VALUABLE MEDICAL BOOKS,

PUBLISHED BY

GRIGG & ELLIOT,

No. 9, North Fourth Street,

PHILADELPHIA.

EBERLE'S PRACTICE OF MEDICINE.—A Treatise on the Theory and Practice of Medicine, in 2 vols. 8vo. By John Eberle, M. D., Professor of Materia Medica and Obstetrics in the Jefferson Medical College, Philadelphia, 2d edition, improved.

This is one of the most valuable works on the Practice of Medicine, that has ever issued from the American or English press.

The distinguished editor of the North American Medical and Surgical Journal, speaking of this work, says—"The work of Dr. Eberle is confessedly one of very great merit. It does much credit to his industry and learning, while it places in a very favourable point of view his abilities as a practitioner. The talents, industry, and variety of research necessary for the production of a System of Practical Medicine, are possessed by few; and when we say, as we do with great candour, that the Treatise before us will bear a very favourable comparison with any modern work of the same class, while it is far superior, as well in regard to the soundness of its pathological views, generally speaking, as to the excellence of its therapeutic precepts, to the more popular of the English systems, we confer upon it and its author no mean praise."

The April No. of Johnson's London Medico-Chirurgical Review, speaking of this work observes, "That this is a very respectable compilation; in fine, superior to Thomas's Practice of Physic in this country."

Although designed chiefly for professional men, it will be found a valuable practical manual for private or domestic reference. If heads of families were to purchase and consult this work instead of the empirical and in many respects misleading compounds so common, they would have the satisfaction of being assured, that nothing but sound and well tested practical directions would be offered them; at the same time they would acquire correct notions concerning the character and systems of diseases. Every person of good understanding may comprehend the practical rules laid down in this work.

To render this invaluable work particularly useful, as a work of reference for family use, a glossary is added of the technical terms used in the work.

A TREATISE ON THE MATERIA MEDICA AND THERAPEUTICS, in 2 vols. Third edition, improved and greatly enlarged. By John Eberle, M. D., Professor of Materia Medica and Obstetrics in the Jefferson Medical College; Member of the American Philosophical Society; Corresponding Member of the Medico-Chirurgical Society, &c.

This work is among the most popular of this distinguished author's works, and ere long will be found in the library of every practical Physician. This fourth edition is much improved.

RUSH ON THE MIND, new fine edition, 1 vol. 8vo.

This work is valuable and highly interesting for intelligent readers of every profession: it is replete with curious and acute remarks, both medical and metaphysical, and deserves particular praise for the terseness of its diction.

COOPER'S FIRST LINES OF THE PRACTICE OF SURGERY: designed as an introduction for students, and a concise book of reference for practitioners. By Samuel Cooper, M. D. With Notes, by Alexander H. Stevens, M. D., and additional Notes, and an Appendix, by Dr. S. M'Clellan. Third American, from the last London edition, revised and corrected. With several new plates and wood cuts, in 2 vols. 8vo.

MEDICAL WORKS.

This work is highly esteemed by all the distinguished of the Medical Profession; and, in many of our Medical Schools, is used as a Text Book.

VELPEAU'S ELEMENTARY TREATISE ON THE ART OF MIDWIFERY, on the Principles of Toxicology and Embryology, in 1 volume, 8vo. Translated from the French, by Charles D. Meigs, M. D., Member of the College of Physicians, &c.

The distinguished editors of the North American Medical and Surgical Journal, after noticing the various works on the subject of the obstetric art, observe: "We have chosen this, because it appears to us to be one of the very best. It is a model for such a work:—the several parts being duly connected, and related and managed with a beautiful simplicity and dexterity, like that used by the naturalist. A sort of nomenclatural neatness and conciseness reigns throughout. It is a book that no physician should be without."

A TREATISE ON THE ANATOMY, PHYSIOLOGY, AND DISEASES OF THE BONES AND JOINTS. In one volume, 8vo. By S. D. Gross, M. D.

MANUAL OF GENERAL ANATOMY, containing a concise description of the Elementary Tissues of the Human Body. From the French of A. L. Bayle and H. Hollard. By S. D. Gross, M. D.

This volume has been highly approved by many of the principal medical men, and has been recommended by several anatomical teachers. "We recommend this little volume to the anatomical student; it contains an excellent account of the primitive tissues, and will greatly facilitate a knowledge of what has been too much neglected in this country, general anatomy."—*Medical Gazette.*

Armstrong's Medical Works.

Williams on Medical Jurisprudence.

⁂ *All the new Medical Works received and for sale as soon as published, on the most reasonable terms.*

BYRON'S WORKS, complete, 1 vol. 8vo., including all his suppressed and Attributed Poems.

MISCELLANEOUS WORKS.

☞ This edition has been carefully compared with the recent London edition of Mr. Murray, and made complete by the addition of more than fifty pages of poems heretofore unpublished in England. Among these there are a number that have never appeared in any American Edition; and the Publishers believe they are warranted in saying that this is the *most complete edition of Lord Byron's Poetical Works*, ever published in the United States.

THE POETICAL WORKS OF MRS. HEMANS, complete, in 1 vol. 8vo.

"As no work in the English language can be commended with more confidence, it will argue bad taste in a female in this country to be without a complete edition of the writings of one who was an honour to her sex and to humanity, and whose productions, from first to last, contain no syllable calculated to call a blush to the cheek of modesty and virtue. There is, moreover, in Mrs. Hemans' poetry a moral purity, and a religious feeling, which commend it in an especial manner, to the discriminating reader. No parent or guardian will be under the necessity of imposing restrictions with regard to the free perusal of every production emanating from this gifted woman. There breathes throughout the whole a most eminent exemption from impropriety of thought or diction—and there is at times a pensiveness of tone, a winning sadness in her more serious compositions, which tells of a soul which has been lifted from the contemplation of terrestrial things, to divine communings with beings of a purer world."

COWPER AND THOMSON'S PROSE AND POETICAL WORKS, complete in 1 vol. 8vo., including two hundred and fifty Letters, and sundry Poems of Cowper, never before published in this country; and of Thomson a new and interesting Memoir, and upwards of twenty new poems, for the first time printed from his own Manuscripts, taken from a late edition of the Aldine Poets, now publishing in London.

The distinguished Professor Silliman, speaking of this edition; observes, "I am as much gratified by the elegance and fine taste of your edition, as by the noble tribute of genius and moral excellence which these delightful authors have left for all future generations; and Cowper especially, is not less conspicuous as a true Christian moralist and teacher, than as a poet of great power and exquisite taste."

GOLDSMITH'S ANIMATED NATURE, in 4 vols. 8vo., illustrated with eighty-five copperplates.

⁂ Goldsmith can never be made obsolete, while delicate genius, exquisite feeling, fine invention, the most harmonious metre, and the happiest diction are at all valued.

This is a work that should be in the library of every family, being written by one of the most talented authors in the English language.

MILTON, YOUNG, GRAY BEATTIE, AND COLLINS' POETICAL WORKS, complete in 1 vol. 8vo.

THE WORKS OF LAURENCE STERNE, in 1 vol. 8vo. with a life of the author, written by himself.

The beauties of this author are so well known, and his errors in style and expression so few and far between, that one reads with renewed delight his delicate turns, &c.

THE POETICAL WORKS OF ROGERS, CAMPBELL, MONTGOMERY, LAMB, AND KIRK WHITE, complete in 1 vol. 8vo.

JOSEPHUS'S (FLAVIUS) WORKS. By the late William Whiston, A. M. From the last London Edition, complete in 2 vols. 8vo.

All those who wish to possess a beautiful and correct copy of this invaluable work, would do well to purchase this edition. It is for sale at all the principal bookstores in the United States, by country merchants generally in the Southern and Western states, and at a very low price.

PREFACE

TO

THE FIRST EDITION.

The objects of a Dispensatory are to present an account of medicinal substances in the state in which they are brought into the shops, and to teach the modes in which they are prepared for use. The importance of these objects, and the general value and even necessity of a work of this nature, will not be disputed. It may, however, be a question, how far the wants of the medical and pharmaceutical community in this country are supplied by the Dispensatories already in circulation; and whether such a deficiency exists as to justify the offer of a new one to the public attention. The great merits of the works severally entitled "The Edinburgh New Dispensatory," and "The London Dispensatory," the former edited by the late Andrew Duncan, M.D., the latter by Anthony Todd Thomson, M.D., are well known wherever the English language is spoken. Founded, as they both are, upon the excellent basis laid by Lewis, they are nevertheless entitled, from the great addition of valuable materials, and the distinctive character exhibited in the arrangement of these materials, to be considered as original works; while the style in which they have been executed speaks strongly in favour of the skill and industry of their authors. But they were calculated especially for the sphere of Great Britain, and are too deficient in all that relates exclusively to this country, to admit of being received as standards here. In the history of our commerce in drugs, and of the nature, growth, and collection of our indigenous medical plants; in the chemical operations of our extensive laboratories; and in the modes of preparing, dispensing, and applying medicines, which have gradually grown into use among us; there is much that is peculiar, a knowledge of which is not to be gained from foreign books, and is yet necessary to the character of an accomplished American pharmaceutist. We have, moreover, a National Pharmacopœia, which requires an explanatory commentary, in order that its precepts may be fully appreciated, and advantageously put into practice. On these accounts it is desirable that there should be a Dispensatory of the United States, which, while it embraces whatever is useful in European pharmacy, may accurately represent the art as it exists in this country, and give instruction adapted to our peculiar wants. It appears due to our national character, that such a work should be in good faith an American work, newly prepared in all its parts, and not a mere edition of one of the European Dispensatories, with here and there additions and alterations, which, though they may be useful in themselves, cannot be made to harmonize with the other materials so as to give to the whole an appearance of unity, and certainly would not justify the assumption of a new and national title for the book. Whether in the Dispensatories which have been published in the United States, these requisites have been satisfactorily fulfilled, it rests with the public to determine. That valuable treatises on Materia Medica and Pharmacy have been issued in this country, no candid person, acquainted with our medical literature, will be disposed to deny. In offering a new work to the medical and pharmaceutical professions, the authors do not wish to be considered as undervaluing the labours of their predecessors. They simply conceive, that the field has not been so fully occupied as to exclude all competition. The pharmacy of continental Europe is ground which has been almost untouched; and much information in relation to the natural history, commerce, and management of our own drugs, has lain ungathered in the possession of individuals, or scattered in separate treatises and periodicals not generally known and read. Since the publication of the last edition of our National Pharmacopœia, no general explanation of its processes has appeared, though required in justice both to that work and to the public. The hope of being able to supply these deficiencies, may, perhaps, be considered a sufficient justification for the present undertaking.

The Pharmacopœia of the United States has been adopted as the basis of this Dispensatory. It is followed both in its general division of medicines, and in its alphabetical arrangement of them under each division. Precedence is, in every instance, given to the names which it recognises; while the explanations by which it fixes the signification of these names, are inserted in immediate connexion with the titles to which they severally belong. Every article which it designates is more or less fully described; and all its processes, after being literally copied, are commented on and explained whenever comment or explanation appeared necessary. Nothing, in fine, has been omitted, which, in the estimation of the authors, could serve to illustrate its meaning or promote the ends which it was intended to subserve. This course of proceeding appeared to be due to the national character of the Pharmacopœia, and to the important object of establishing, as far as possible, throughout the United States, uniformity both in the nomenclature and preparation of medicines. In one particular, convenience required that the plan of the Pharmacopœia should be departed from. The medicines belonging to the department of MATERIA MEDICA, instead of being arranged in two divisions, corresponding with the *Primary* and *Secondary Catalogues* of that work, have been treated of indiscriminately in alphabetical succession; and the place which they respectively hold in the Pharmacopœia is indicated by the employment of the term *Secondary*, in connexion with the name of each of the medicines included in the latter catalogue.

But though precedence has thus been given to the Pharmacopœia of the United States, those of Great Britain have not been neglected. The nomenclature adopted by the different British Colleges, and their formulæ for the preparation of medicines, have been so extensively followed throughout the United States, that a work intended to represent the present state of pharmacy in this country would be imperfect without them; and the fact that the writings of British physcians and surgeons, in which their own officinal terms and preparations are exclusively employed and referred to, have an extensive circulation among us, renders some commentary necessary in order to prevent serious mistakes. The Pharmacopœias of London, Edinburgh, and Dublin, have, therefore, been incorporated, in all their essential parts, into the present work. Their officinal titles are uniformly given—always in subordination to those of the United States Pharmacopœia, when they express the same object; but in chief, when, as often happens, no corresponding medicine or preparation is recognised by our national standard. In the latter case, if different names are applied by different British Colleges to the same object, that is generally preferred which is most in accordance with our own system of nomenclature, and the others are given as synonymes. The medicines directed by the British Colleges are all described, and their processes either copied at length, or so far explained as to be intelligible in all essential particulars.

Besides the medicinal substances recognised as officinal by the Pharmacopœias alluded to, some others have been described, which, either from the lingering remains of former reputation, or from recent reports in their favour, or from their important relation to medicines in general use, appear to have claims upon the attention of the physician and apothecary. Opportunity has, moreover, been taken to introduce incidentally brief accounts of substances used in other countries or in former times, and occasionally noticed in medical books; and that the reader may be able to refer to them when desirous of information, their names have been placed with those of the standard remedies in the Index.

In the description of each medicine, if derived immediately from the animal, vegetable, or mineral kingdom, the attention of the authors has been directed to its natural history, the place of its growth or production, the method of collecting and preparing it for market, its commercial history, the state in which it reaches us, its sensible properties, its chemical composition and relations, the changes which it undergoes by time and exposure, its accidental or fraudulent adulterations, its medical properties and application, its economical uses, and the pharmaceutical treatment to which it is subjected. If a chemical preparation, the mode and principles of its manufacture are indicated in addition to the other particulars. If a poison, and likely to be accidentally taken, or purposely employed as such, its peculiar toxicological effects, together with the mode of counteracting them, are indicated; and the best means of detecting its presence by reagents are explained.

The authors have followed the example of Dr. A. T. Thomson, in giving botanical descriptions of the plants from which the medicines treated of are derived. In relation to all indigenous medicinal plants, and those naturalized or cultivated in this country, the advantages of such descriptions are obvious. The physician may often be placed in situations, in which it may be highly important that he should be able to recognise the vegetable which yields a particular medicine; and the apothecary is constantly liable to imposition from the collectors of herbs, unless possessed of the means of distinguishing by infallible marks the various products presented to him. A knowledge of foreign medicinal plants, though of less importance, will be found useful in various ways, independently of the gratification afforded by the indulgence of a liberal curiosity in relation to objects so closely connected with our daily pursuits. The introduction of these botanical notices into a Dispensatory appears to be peculiarly appropriate, as they are to be considered rather as objects for occasional reference than for regular study or continuous perusal, and therefore coincide with the general design of the work, which is to collect into a convenient form for consultation all that is practically important in relation to medicines. The authors have endeavoured to preserve a due proportion between the minuteness of the descriptions, and their value as means of information to the student; and, in pursuance of this plan, have generally dwelt more at length upon our native plants, than upon those of foreign growth: but in all instances, in which they have deemed any botanical description necessary, they have taken care to include in it the essential scientific character of the genus and species, with a reference to the position of the plant in the artificial and natural systems of classification; so that a person acquainted with the elements of botany may be able to recognise it when it comes under his observation.

In preparing the Dispensatory, the authors have consulted, in addition to many of the older works of authority, the greater number of the treatises and dissertations which have recently appeared upon the various subjects connected with Pharmacy, and especially those of the French writers, who stand at present at the head of this department of medical science. They have also endeavoured to collect such detached facts scattered through the various scientific, medical, and pharmaceutical journals, as they conceived to be important in themselves, and applicable to the subjects under consideration; and have had frequent recourse to the reports of travellers in relation to the natural and commercial history of foreign drugs. The occasional references in the body of the work will indicate the sources from which they have most largely drawn, and the authorities upon which they have most relied. In relation to our own commerce in drugs and to the operations of our chemical laboratories, they are indebted for information chiefly to the kindness of gentlemen engaged in these branches of business, who have always evinced, in answering their numerous inquiries, a promptitude and politeness which merit their warm thanks, and which they are pleased to have this opportunity of acknowledging.*

It has not been deemed necessary to follow the example of the British Dispensatories, by inserting into the work a treatise upon Chemistry under the name of Elements of Pharmacy. Such a treatise must necessarily be very meagre and imperfect; and, as systems of chemistry are in the hands of every physician and apothecary, would uselessly occupy the place of valuable matter of less easy access.

---

* The authors deem it proper to state that they are peculiarly indebted for assistance to Mr. Daniel B. Smith, president of the Philadelphia College of Pharmacy, to whom, besides much important information in relation to the various branches of the Apothecary's business, they owe the prefatory remarks on Pharmacy which are placed at the commencement of the second part of the work, and the several articles, in the Materia Medica, upon *Leeches*, *Litmus*, and the *Carbonate* and *Sulphate of Magnesia*.

The authors may perhaps be permitted to observe, in relation to themselves, that they have expended much time and labour in the preparation of the work; have sought diligently for facts from every readily accessible source; have endeavoured by a comparison of authorities, and a close scrutiny of evidence, to ascertain the truth whenever practicable; and have exerted themselves to the extent of their abilities to render the Dispensatory worthy of public approbation, both for the quality and quantity of its contents, and the general accuracy of its statements. They are conscious, nevertheless, that in so great a multiplicity of details numerous errors and deficiencies may exist, and that the faults of undue brevity in some cases, and prolixity in others, may not have been entirely avoided: but they venture to hope that a candid public will make all due allowances; and they take the liberty to invite from all those who may feel interested in the diffusion of sound pharmaceutical knowledge, the communication of friendly suggestions or criticisms in relation to the objects and execution of the work.

Philadelphia, January, 1833.

PREFACE

TO

THE THIRD EDITION.

In preparing the second edition of the Dispensatory, the authors bestowed much labour upon the work, correcting errors, curtailing superfluities, and supplying deficiencies, whenever observed, and enlarging the original plan by the addition of an Appendix, containing notices and descriptions of numerous drugs, which, though not recognised in the American or British Pharmacopœias, were possessed of some interest from their former or existing relations to Medicine and Pharmacy. Their object was to compress, within convenient limits, all the information concerning medicinal substances which could be deemed essential or peculiarly interesting to the physician and apothecary. They are gratified in being able to infer, from the rapidity with which the late edition, though a large one, has been exhausted, that the public confidence has not been withdrawn from the work. In its revision for the present edition, they have endeavoured to render it still more worthy of this confidence by correcting errors which had previously escaped their notice, introducing whatever new facts and views have been developed in the progress of research, and bringing it, in all respects, as nearly as possible, to a level with the existing state of knowledge in relation to Materia Medica and Pharmacy. Several substances, not noticed in the former editions, have been treated of in the present; and a table of pharmaceutical equivalents has been introduced into the Appendix, which will be found very convenient for reference, both to the student and practitioner. It may be proper in addition to mention, that a few articles, treating of substances not included in the officinal catalogues, have been transferred from the Materia Medica to the Appendix; so that the first part of the work is now devoted exclusively to the consideration of those medicines which are recognised as such, either in the British Pharmacopœias, or in that of the United States. The authors avail themselves of this opportunity to offer their best thanks to those who have kindly pointed out errors or defects which had escaped their own attention; and they repeat their invitation for such friendly suggestions as may contribute to render the Dispensatory more useful, should it reach another edition.

Philadelphia, June, 1836.

Abbreviations employed in the Work.

U. S.—"THE PHARMACOPŒIA OF THE UNITED STATES OF AMERICA. By authority of the National Medical Convention, held at Washington, A. D. 1830."

Lond.—LONDON PHARMACOPŒIA, A. D. 1824.

Ed.—EDINBURGH PHARMACOPŒIA, A. D. 1817.

Dub.—DUBLIN PHARMACOPŒIA, A. D. 1826.

Off. Syn.—OFFICINAL SYNONYMES, or the titles employed by the Pharmacopœias with the accompanying explanations, when these titles are not given in chief.

Sex. Syst.—The SEXUAL SYSTEM, or the artificial system of Linnæus, founded on the sexual organization of plants.

Nat. Ord.—The NATURAL ORDER to which any particular genus of plants belongs. When not otherwise stated, it is to be understood that the natural orders referred to are those recognised by Professor Lindley, of the University of London, in his "Introduction to the Natural System of Botany."

Gen. Ch.—The GENERIC CHARACTER, or scientific description of any particular genus of plants under consideration.

Off. Prep.—OFFICINAL PREPARATIONS; including all the preparations into which any particular medicine directed by the U. S. Pharmacopœia and the British Colleges enters. When the same preparation has received different names in the different Pharmacopœias, only one of these names is mentioned, and precedence is always given to that of the U. S. Pharmacopœia.

Sp. Gr.—SPECIFIC GRAVITY.

Equiv., or *Eq.*—CHEMICAL EQUIVALENT, or the number representing the smallest quantity in which one body usually combines with others.

THE DISPENSATORY OF THE UNITED STATES.

PART I.

MATERIA MEDICA.

The Materia Medica, in its most comprehensive sense, embraces all those substances which are capable of making sanative impressions on the human system; but, as the term is employed in this work, it has a more restricted signification. The Pharmacopœias of the United States and Great Britain very appropriately arrange medicines in two distinct divisions, one including all those which are furnished immediately by nature, or thrown into commerce by the manufacturer; the other, those which are prepared by the apothecary, and are the objects of officinal directions. The former are enumerated under the title of "Materia Medica;" the latter under that of "Preparations," or "Preparations and Compositions." In Dispensatories, which may be considered as commentaries on the Pharmacopœias, the same arrangement is usually followed; and the authors of the present work adopt it the more willingly, as, independently of the weight of authority in its favour, it has the recommendation of being the most convenient. By this plan, all the directions which relate to the practical operations of the apothecary are collected in one place, and are thus more easily referred to, than if mixed indiscriminately with other matters, as they must be by any mode of arrangement which makes no distinction between the original medicinal substances and their preparations. Under the head of Materia Medica, therefore, in this Dispensatory, we treat of medicines in the state only in which they are produced by nature, or come into the hands of the apothecary. Of these medicines, such as are recognised by our National Pharmacopœia are most minutely described; but we consider also all that are included in the officinal catalogues of the British Colleges.

Another point in which we accord with the Pharmacopœias, is the alphabetical arrangement of the objects of the Materia Medica. As a Dispensatory is intended rather for reference than for regular perusal, it is important that its contents should be so disposed as to facilitate consultation. Medicines, in a work of this kind, are considered as independent objects, to be studied separately, and without any reference to community of source, or similarity of character. Their scientific classification belongs to works which treat of them rather in their relations than their essential properties; and different systems have been adopted, according to the set of relations towards which the mind of the author has been especially directed. Thus, the naturalist classifies them according to the affinities of the several objects in nature from which they are derived; the chemist, according to their composition; the practitioner of medicine, according to their effects upon the system in a state of health and disease. But none of these classifications is without imperfections; and a simple alphabetical arrangement is decidedly preferable in every case in which the medicines are considered solely in their individual capacity. Yet, as it comes within the scope of this work to treat of their physiological and therapeutical effects, and as the terms by which these effects are expressed are also the titles of classes to which the medicines belong, it will not be amiss to present the reader with the outlines of a system of classification, by consulting which he will be enabled to ascertain the precise meaning we attach to the terms employed to designate the peculiar action of different medicinal substances.

Remedies are divided into general and local, the former acting on the whole system, the latter on particular parts or organs.

I. GENERAL REMEDIES include 1. SIMPLE STIMULANTS, sometimes called INCITANTS, which, while they raise the actions of the system above the standard of health, exhibit their influence chiefly upon the heart and arteries; 2. NARCOTICS, which especially affect the cerebral functions, and are either *stimulant* or *sedative* according as they increase or diminish the natural actions; 3. ANTISPASMODICS, which, with a general stimulant power, exert a peculiar influence over the nervous system, exhibited in the relaxation of spasm, the calming of nervous irritation, &c.; without any special and decided tendency to the brain; 4. TONICS, which moderately and permanently exalt the energies of all parts of the frame, without necessarily producing any apparent increase of the natural actions; and 5. ASTRINGENTS, which, with more or less tonic power, have the property of producing contraction in the living fibre wherever they come in contact with it.

II. LOCAL REMEDIES may be divided into four sections: *a. Those affecting the function of a part*, namely, 1. EMETICS, which act on the stomach, producing vomiting; 2. CATHARTICS, which act on the bowels, producing a purgative effect; 3. DIURETICS, which act on the kidneys, producing an increased flow of urine; 4. ANTILITHICS, which act on the same organs, preventing the formation of calculous matter; 5. DIAPHORETICS, which increase the cutaneous discharge; 6. EXPECTORANTS, which augment the secretion from the mucous membrane of the bronchi, or promote the discharge of the secreted matter; 7. EMMENAGOGUES, which excite the menstrual secretion; 8. SIALAGOGUES, which increase the flow of saliva; and 9. ERRHINES, which increase the discharge from the mucous membrane of the nostrils: *b. Those affecting the organization of a part*, including 1. RUBEFACIENTS, which produce redness and inflammation of the skin; 2. EPISPASTICS or VESICATORIES, which produce a serous discharge beneath the cuticle, forming a blister; and 3. ESCHAROTICS or CAUSTICS, which destroy the life of the part upon which they act: *c. Those operating by a mechanical agency*, consisting of 1. DEMULCENTS, which lubricate the surface to to which they are applied, and prevent the contact of irritating substances, or mingle with these and diminish their acrimony; and 2. EMOLLIENTS, which serve as vehicles for the application of warmth and moisture, at the same time excluding the air: *d. Those which act on extraneous matters contained within the organs*, including 1. ANTHELMINTICS, which destroy worms or expel them from the bowels; and 2. ANTACIDS, which neutralize acid, whether existing in the alimentary canal, or circulating with the blood.

It is believed that all substances employed as medicines, with the exception of a very few which are so peculiar in their action as scarcely to admit of classification, may be distributed without violence among the above classes. Some substances, however, in addition to the properties of the classes to which they are severally attached, possess others in common, which give them practical value, and authorize their association in distinct groups, not recognized in the system of classification, but constantly referred to in medical language. Thus we have REFRIGERANTS, which, when internally administered, diminish animal temperature; ALTERATIVES, which change, in some inexplicable and insensible manner, certain morbid actions of the system; and CARMINATIVES, which, by promoting contraction in the muscular coat of the stomach and bowels, cause the expulsion of flatus. It is common, moreover, to attach distinct names to groups of remedies, with reference to certain effects which are incident to the properties that serve to arrange them in some more comprehensive class. Thus NARCOTICS frequently promote sleep and relieve pain, and in relation to these properties are called SOPORIFICS and ANODYNES; and various medicines, which by diversified modes of action serve to remove chronic inflammation and enlargements of the glands or viscera, are called DEOBSTRUENTS. These terms are occasionally employed in the following pages, and are here explained, in order that the sense in which we use them may be accurately understood. W.

ACACIÆ GUMMI. *U.S.*

Gum Arabic.

"Acacia vera. Succus concretus. *The concrete juice.*" *U.S.*

Off. Syn. ACACIÆ GUMMI. Acacia vera. Gummi. *Lond.;* ACACIÆ ARABICÆ GUMMI. Ex variis Acaciæ speciebus. *Ed.;* ACACIA ARABICA et ACACIA VERA. Gummi. *Dub.*

Gomme Arabique, *Fr.;* Arabisches Gummi, *Germ.;* Gomma Arabica, *Ital.;* Goma Arabiga, *Span.;* Samagh Arebee, *Arab.*

ACACIA. *Sex. Syst.* Polygamia Monœcia.—*Nat. Ord.* Leguminosæ, *Trib.* Mimoseæ.

This genus is one of those into which the old genus Mimosa of Linnæus was divided by Willdenow. The name *Acacia* was employed by the ancient Greeks to designate the gum-tree of Egypt, and has been appropriately applied to the new genus in which that plant is included.

Gen. Ch. HERMAPHRODITE. *Calyx* five-toothed. *Corolla* five-cleft, or formed of five petals. *Stamens* 4–100. *Pistil* one. *Legume* bivalve. MALE. *Calyx* five-toothed. *Corolla* five-cleft, or formed of five petals. *Stamens* 4–100. *Willd.*

Several species of Acacia contribute to furnish the gum Arabic of the shops. Those which have attracted most attention are the *A. vera* and *A. Arabica*, confounded together by Linnæus under the title of *Mimosa Nilotica.**

Acacia vera. Willd. *Sp. plant.* iv. 1805; Hayne, *Darstel. und Beschreib. &c.* x. 34. This is a tree of middling size, with numerous scattered branches, of which the younger are much bent, and covered with a reddish-brown bark. The leaves are alternate and bipinnate, with two pairs of pinnæ, of which the lower are usually furnished with ten pairs of leaflets, the upper with eight. The leaflets are very small, oblong-linear, smooth, and supported upon very short footstalks. On the common petiole is a gland between each pair of pinnæ. Both the common and partial petiole are smooth. Two sharp spines or rather prickles, from a quarter to half an inch long, of the colour of the smaller branches, and joined together at their base, are found at the insertion of each leaf. The flowers are yellow, inodorous, small, and collected in globular heads supported upon slender peduncles, which rise from the axils of the leaves, in number from two to five together. The fruit is a smooth, flat, two-valved legume, divided by contractions, occurring at regular intervals, into several roundish portions, each containing a single seed. This species flourishes in Upper Egypt and Senegal, and is probably scattered over the whole intervening portions of the African continent. The Acacia of the Cape of Good Hope, considered by Sparrman and Thunberg as the Mimosa Nilotica of Linn., and hence treated by some authors as identical with the present species, appears to be distinct, and has received the name of *Acacia Karroo*. It exudes a gum, which is said to be used at the Cape.

---

* Since the publication of the first edition of this Dispensatory, we have had an opportunity of examining Hayne's great work on medical plants, entitled *Getreue Darstellung und Beschreibung der in der Arzneykunde gebräuchlichen Gewächse*, &c., which has been for several years in the course of publication at Berlin. The account of the Acacias which yield gum Arabic, presented by this author, is the most satisfactory that we have seen; and we have freely availed ourselves in the present edition of the information which he furnishes. This is the more valuable, as much of it was derived from Dr. Ehrenberg, a scientific German traveller, who visited many of the regions where gum Arabic is collected, and had an opportunity of personally inspecting the plants from which it is derived.—*Note to second edition.*

A. Arabica. Willd. *Sp. Plant.* iv. 1805; Hayne, *Darstel. und Beschreib.* x. 32.—*Acacia Nilotica*, Delil. *Ill. flor. de l'Egypt.* p. 79.—*Acacia vera.* Vesling. *Ægypt.* p. 8. This species, though often little more than a shrub, attains in favourable situations the magnitude of a considerable tree, being sometimes forty feet high, with a trunk a foot or more in diameter. The leaves are alternate and doubly pinnate, having from four to six pairs of pinnæ, each of which is furnished with from ten to twenty pairs of minute, smooth, oblong-linear leaflets. The common petiole has a gland between the lowest pair of pinnæ, and often also between the uppermost pair. Both the common and partial petiole, as well as the young branches, are downy. The prickles are straight, and disposed as in the former species. The flowers are also arranged as in the A. vera, and the fruit is of a similar shape. The A. Arabica is perhaps the most widely diffused of the gum-bearing species. It grows in Upper and Lower Egypt, Senegal, and other parts of Africa, flourishes also in Arabia, and is abundant in Hindostan, where its gum is used for food by the natives.

Besides the two species above described, the following afford considerable quantities of gum:—The *A. Senegal*, a small tree, inhabiting the hottest regions of Africa, and said to form vast forests in Senegal; the *A. gummifera*, seen by Broussonet in Morocco near Mogador; the *A. Ehrenbergiana*, a shrub six or eight feet high, named in honour of the German traveller Ehrenberg, who observed it in the deserts of Lybia, Nubia, and Dongola; the *A. Seyal*, growing in the same countries with the last mentioned species, and also in Upper Egypt; and the *A. tortilis*, which sometimes attains the height of sixty feet, and inhabits Arabia Felix, Nubia, Dongola, and the Lybian desert. It is highly probable that gum is obtained also from other species not hitherto described, growing in the hot latitudes of Africa. The *A. decurrens* and *A. floribunda*, natives of New Holland, yield by exudation a tolerably pure gum, which has not yet, however, been extensively collected. Other trees, moreover, not belonging to the genus, afford a similar product, especially the *Feronia elephantum* of Hindostan, the gum of which, according to Ainslie, is used for medical purposes by all the practitioners of Lower India.

The gum-bearing Acacias are all thorny or prickly trees or shrubs, calculated by nature for a dry and sandy soil, and flourishing in deserts where few other trees will grow. We are told that camels attached to the caravans derive from them their chief sustenance in many parts of those desolate regions in which Africa abounds. In these situations they have a stunted growth, and present a bare, withered, and uninviting aspect; but in a favourable situation, as on the banks of rivers, they often assume a luxuriant and elegant appearance.

Their bark and unripe fruit contain tannin and gallic acid, and are sometimes used for tanning leather. An extract was formerly obtained from the immature pods of the *A. Arabica* and *A. vera*, by expression and inspissation. It was known to the ancients by the name of *acaciæ veræ succus*, and was highly lauded by some of the Greek medical writers. It is at present little used, though described in most of the European works on Pharmacy. It is a solid, heavy, shining, reddish-brown substance, of a sweetish, acidulous, styptic taste, and soluble in water. Its virtues are probably those of a mild astringent. On the continent of Europe, a preparation is said to be usually substituted for it called *acacia nostras*, obtained by expression and inspissation from the unripe fruit of the *Prunus spinosa*, or wild plum tree.

The gum of the Acacias exudes spontaneously from the bark of the trunk and branches, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. This is supposed by some to be favoured by disease, and it is stated by Jackson, that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential; for in cooler climates, though the tree may flourish, it yields no gum. According to Ehrenberg, the varieties in the colour and other characters of the gum do not depend upon difference in the species of the plant. Thus, from the same tree, the gum will exude frothy or thick, and clear or dark coloured, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce.

Commercial History. Gum Arabic was formerly procured, chiefly, if not exclusively, from Egypt and the neighbouring countries; and much is still obtained from the same sources. It is collected in Upper Egypt, Nubia, and Darfur, whence it is taken down the Nile to Alexandria. A considerable quantity is also brought to the same port from Arabia. We obtain it in this country through Smyrna, Trieste, Marseilles, or some other entrepot of the Mediterranean commerce. Two varieties of the gum have long been noticed, one more or less coloured, the other white, which were formerly, and, on the continent of Europe, are still distinguished by the titles of *gum gedda*, and *gum turic*, derived from the ports of the Red Sea, Jidda and Tor, from which the varieties were erroneously supposed to be respectively exported. The gum from Egypt is commonly known to our druggists by the name of *Turkey gum*, and is the kind with which the apothecaries are usually supplied. Though interspersed with roundish pieces of various sizes, it consists chiefly of small, irregular fragments, which are commonly whitish, or slightly tinged with yellow or reddish-yellow. It is on the whole lighter coloured, more brittle, more readily soluble, and much freer from impurities than the other commercial varieties, and contains much of that form of gum Arabic, which is characterized by innumerable minute fissures pervading its substance, and impairing its transparency. The best comes in cases.

Much gum Arabic is at present obtained from Barbary; and Mogador, a port of Morocco, is the chief entrepot of the trade. According to Jackson, the natives call the tree which affords it *attaleh*. They gather it in the months of July and August, when the weather is hot and very dry. Two kinds are brought to Mogador, one from the neighbouring provinces, the other by caravans from Timbuctoo. This may account for the fact that the *Barbary gum* in part resembles the Turkey, in part the Senegal. When first deposited in the warehouses, it has a faint smell, and makes a crackling noise, occasioned by the spontaneous rupture of the small masses as they become more dry. The Barbary gum is exported in casks, and reaches the U. States through the route of English commerce.

Gum Senegal, which is a mere commercial variety of this drug, was first introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade; but since the last great European war, it has been largely shared by the English. St. Louis, at the mouth of the Senegal, and Portendic, considerably further north, are the ports in which the commerce in gum has chiefly centered. Immense forests of the Acacia exist at some distance in the interior. These are composed chiefly of two different trees, called by the natives *vereck* or *nereck*, and *nebuel*, or *nebued*, the former of which yields a white gum, the latter a red. These are probably distinct species, the *vereck* being, according to M. Rain, the *A. vera*, and the *nebuel* the *A. Senegal.* According to Adanson, there are several other species in the neighbourhood which yield gum. In the month of November the juice begins to exude from the trees. The dry winds which prevail after the rainy season, cause the bark to crack; the juice flows out, and hardens in masses, which are often as large as a pigeon's egg, and sometimes, according to M. Rain, as large as the egg of the ostrich. At this period the Moors and Negroes proceed to the forests in caravans, collect the gum in leather sacs, and convey it to the coast, where they exchange it for British goods. When stowed in the warehouses, it presents the phenomena before noticed in relation to the Barbary gum. The slight odour at first emitted ceases after a few weeks, and the masses no longer crack when perfectly dry. This variety of gum is imported into the United States chiefly from Bordeaux. It is usually in roundish or oval unbroken pieces, sometimes whitish, but generally yellowish or reddish, or brownish-red, larger than those of the Turkey gum, less brittle and pulverizable, and breaking with a more conchoidal fracture.

Considerable quantities of gum are imported into this country from India. Ainslie states that it is derived from the *A. Arabica;* and it is not improbable that much of it is taken to Calcutta in the Arab vessels from the ports of the Red Sea. It is in pieces of various size, colour, and quality, some resembling the broken fragments of the Turkey gum, though much less chinky; others large, roundish, and tenacious, like the Senegal. Its taste is sweeter than that of the other varieties. It is usually much contaminated, containing, besides the genuine gum Arabic, portions of a different kind of gum, having the characteristic properties of that known by the name of Bassora. This is distinguished by its insolubility in water, with which, however, it unites, swelling up, and forming a soft viscid mass. It owes its properties to the presence of bassorin. The pieces of this gum bear a considerable resemblance to those of the genuine article, and may easily escape detection. Their want of solubility, however, is a ready test. More or less of a similar substance is found in the parcels of gum Arabic from other sources; and we have seen some said to have come from Barbary, chiefly composed of it. Besides this impurity in the India gum, there are often others more readily detected. Among these, we have observed a yellowish-white resinous substance, which has the sensible properties of the turpentines. If proper care be used in assorting this commercial variety, it may be employed for all the purposes of good gum Arabic. The *India gum* is brought into this country partly from Calcutta, partly by way of England. It usually comes in large cases. We have seen a parcel of gum said to have come directly from the Red Sea, enclosed in large sacs made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size.

In consequence of the presence of impurities, and of the difference in its quality, gum Arabic should generally be assorted for pharmaceutical use.

General Properties. Gum Arabic is in roundish or amorphous pieces, or irregular fragments of various sizes, more or less transparent, hard, brittle, pulverizable, and breaking with a shining fracture. It is usually white, or yellowish-white; but frequently presents various shades of red, and is sometimes of a deep orange or brownish colour. It is bleached by exposure to the light of the sun. In powder it is always more or less purely white. It is inodorous, has a very feeble slightly sweetish taste, and when pure, dissolves wholly away in the mouth. The specific gravity varies from 1.31 to 1.48. (*Berzelius.*) Gum Arabic consists essentially of a peculiar proximate principle of plants usually called *gum*, but for which the name of *arabin*,* originally proposed by Chevreul, has been recently adopted by the French chemists. In describing its chemical relations, therefore, we describe those of the principle alluded to. Water, either cold or hot, dissolves it, and forms a viscid solution called mucilage, which when evaporated, yields the gum unchanged. (See *Mucilago Acaciæ.*) It is insoluble in alcohol, ether, and the oils; and alcohol precipitates it from its aqueous solution. The diluted acids dissolve it, but not more freely than water. The concentrated acids decompose it. Triturated with sulphuric acid, at ordinary temperatures, it is converted into a substance similar to the gummy product which results from the action of the same acid on linen rags or saw-dust. Heated with concentrated sulphuric acid, it is decomposed, with the evolution of carbon. The diluted acid, when boiled with it, gives rise to the formation of a saccharine substance. Strong nitric acid converts it into mucic acid, and at the same time produces oxalic and malic acids. It combines with several of the salifiable bases. With the alkalies and earths it forms soluble compounds. By the subacetate of lead it is precipitated from its solution, in the form of a white insoluble compound of gum and protoxide of lead; and a delicate test of its presence in any liquid is thus afforded. It enters into combination with several salts. A solution of borax coagulates it. When added to a solution of silicate of potassa, it precipitates a compound of gum, potassa, and silica, while a compound of gum and potassa remains dissolved. It is distinguished from other gums by affording a yellow or orange precipitate with the solution of persulphate of iron, and a precipitate insoluble in nitric acid, with even a dilute solution of the permuriate of iron. (*Berzelius.*) In solution, it unites with sugar; and the liquid, when evaporated, yields a transparent, solid substance, which is not susceptible of crystallization.

Gum Arabic undergoes no change by time when kept in a dry place. Its aqueous solution, if strong, remains for a considerable length of time unaltered, but ultimately becomes sour in consequence of the production of acetic acid. At a temperature between 300° and 400°, the gum becomes soft, and may be drawn into threads. At a red heat it is decomposed, yielding, among other substances, a minute proportion of ammonia. When burnt, it leaves about three per cent. of ashes, consisting, according to Guérin, of the carbonates of potassa and of lime, a little phosphate of lime, chloride of potassium, oxide of iron, alumina, magnesia, and silica. The lime exists in the gum combined with an excess of malic acid, which gives to its solution the property of reddening litmus paper. Besides pure gum or arabin, gum Arabic contains a very small proportion of some azotized body, several saline substances, and a considerable quantity of uncombined water, amounting, according to Guérin, to 16 or 17 per cent. Pure gum may be obtained by treating the compound of gum and protoxide of lead with sulphuretted hydrogen. Its constituents, according to Gay-Lussac and Thenard, are carbon 42.23, oxygen 50.84, and hydrogen 6.93; or carbon 42.23, and water 57.77; and this result accords very closely with that obtained by Berzelius. The analysis of Guérin is somewhat different, from the circumstance that he succeeded in depriving the gum more thoroughly of moisture.

---

* Much confusion has existed in the use of the word *gum*, which has been employed to express various concrete vegetable juices, and, at the same time, a peculiar proximate principle of plants. It is now proposed to restrict the term to the former of these applications, and to designate the principle alluded to by a distinct name. Within a few years the subject of the gums has been investigated by M. Guérin, who has repeated and corrected the experiments of former chemists, and thrown new light upon the nature of these substances. Several of the facts mentioned in the text have been derived from his memoir, published in the *An. de Chim. et de Phys.* t. XLIX. p. 248. M. Guérin considers as characteristic of gums, the property of affording mucic acid, when acted on by nitric acid. He recognizes in the different gums three distinct proximate principles; namely, 1. *arabin*, or the pure gum of chemical writers, which is the essential constituent of gum Arabic in all its varieties; 2. *bassorin*, which enters largely into the composition of Bassora gum and tragacanth; and 3. *cerasin*, which constitutes the portion of cherry gum insoluble in cold water. Of arabin sufficient is said in the text. Bassorin will be treated of under the the head of Bassora gum. Of *cerasin* it may be proper to say a few words in this place. The gums which exude from the cherry, apricot, peach, and plum trees, and which the French call *gomme du pays*, appear to be identical in composition, consisting of a portion soluble in cold water, which is arabin, and a portion insoluble, which was formerly thought to be the same with bassorin, but has been proved by M. Guérin to be different, and is appropriately denominated cerasin. This principle is colourless, semitransparent, tasteless, inodorous, uncrystallizable, insoluble in alcohol, insoluble in cold water, in which it softens and swells a little, and convertible by the action of boiling water into arabin, with which it appears to be isomeric. In this last property it differs materially from bassorin, which is not changed by boiling water. M. Guérin suggests that the natural heat of the climate in tropical countries produces the same effect upon the exuded gums as artificial heat in colder regions, and that consequently the acacia gum consists chiefly of arabin.

The properties above described belong to gum Arabic generally. There are, however, pharmaceutic varieties differing from each other to a degree and in a manner which deserve notice. 1. *Gum that is transparent and readily soluble.* This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey gum and gum Senegal. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscidity of its solution. Under this head may be included the *gomme blanche fendillée* of Guibourt, and other French writers. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light; but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the pieces are somewhat opaque, each of the minute fragments into which they may be broken is perfectly transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medical use, and for most purposes in pharmacy. 2. *Gum less transparent and less soluble.* Guibourt has proposed for this variety the name of *gomme pelliculée*, from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Its transparency is less perfect than that of the former variety; it is less quickly and less completely dissolved by water, and forms a more viscid solution. It melts with difficulty in the mouth, and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. In Europe it is frequently called *gum Gedda.* Between these two varieties of gum there are insensible gradations, so that it would be difficult always to classify the specimens which may come under notice.

Medical Properties and Uses. This gum is used in medicine, chiefly as a demulcent. By the viscidity of its solution, it serves to cover and sheathe inflamed surfaces; and by blending with and diluting irritating matters, tends to blunt their acrimony. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed slowly to dissolve. Internally administered it has been found especially useful in inflammatory affections of the gastric and intestinal mucous membrane; and its employment has even been extended to similar affections of the lungs and urinary organs. Whether it is beneficial in the latter cases in any other manner than by the dilution resulting from its watery vehicle, is a doubtful point. By some physicians it is thought to possess a positively sedative influence over the action of inflamed surfaces to which it is applied in the state of solution. As an article of diet in febrile cases, and others requiring an adherence to a very rigid regimen, it is perhaps superior to almost any other substance. If not positively sedative, it is certainly not in the least irritating, while it is sufficiently nourishing to prevent the injurious action of the organs upon themselves. Its nutritive properties have been denied; but the fact of their existence rests on incontrovertible evidence. The Moors and Negroes live on it almost exclusively during the period of its collection and conveyance to market; the Bushmen Hottentots, in times of scarcity, support themselves upon it for days together; and we are told that the apes of South Africa are very fond of it. Six ounces a day are said to be sufficient to sustain life in a healthy adult. In many cases of disease, its solution may with propriety constitute the exclusive drink and food of the patient. It is best prepared by dissolving an ounce of the gum in a pint of boiling water, and allowing the solution to cool. In pharmacy, gum Arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches.

ACETOSÆ FOLIA. *Lond.*

Sorrel Leaves.

"Rumex Acetosa. *Folia.*" *Lond.*

Off. Syn. RUMICIS ACETOSÆ FOLIA, *Ed.;* RUMEX ACETOSA. Folia. *Dub.*

Oseille des jardins, *Fr.;* Sauerampfer, *Germ.;* Acetosa, *Ital.;* Azedera, *Span.*

Rumex. See RUMEX AQUATICUS.

Several species of Rumex have acid leaves, and are distinguished by the common name of *sorrel* from the others which are called *dock*. Two only deserve particular notice, the *R. Acetosa*, or common English sorrel, which is sometimes cultivated in our gardens, and the *R. Acetosella*, or common sorrel of our fields.

Rumex Acetosa. Willd. *Sp. Plant.* ii. 260.; Woodv. *Med. Bot.* p. 660. t. 230. This is a perennial herbaceous plant, with a striated leafy stem, branching at top, and rising one or two feet in height. The radical leaves are narrow, oblong, arrow-shaped, and supported on long foot-stalks; those attached to the stem are alternate, pointed, and clasping. The flowers are diœcious, in terminal panicles, and partly tinged of a red colour.

R. Acetosella. Willd. *Sp. Plant.* ii. 260.; *Eng. Bot.* 1574. The common field sorrel is also an herbaceous perennial, with a stem from four to twelve inches high, and lanceolate-hastate leaves, having the lobes spreading or recurved. The male and female flowers are on separate plants. The valves are without grains. The flowers appear in May, June, and July. Though abundant in the light sandy or gravelly soils of this country, it is supposed by some botanists to have been introduced from Europe.

Sorrel leaves are pleasantly sour, and without odour. Their acidity is dependent on the presence of binoxalate of potassa, with a small proportion of tartaric acid. Starch and mucilage are also among their constituents. Their taste is almost entirely destroyed by drying.

They are refrigerant and diuretic, and may be used with great advantage, as an article of diet, in scorbutic complaints. They are prepared in the form of salad, or boiled like spinage. The juice of the fresh leaves forms with water a pleasant acidulous drink, sometimes given in fevers. W.

Gen. Ch. *Calyx* five-leaved. *Petals* five, connected by the claws. *Stamens* unequal, the five shorter exterior ones connected at the base. *Capsules* opening elastically at the corners, five-angled. *Seeds* covered with an arillus. *Pursh.*

Oxalis Acetosella. Willd. *Sp. Plant.* ii. 780.; Woodv. *Med. Bot.* p. 563. t. 201. The wood-sorrel is a small perennial, herbaceous, stemless plant, with numerous radical leaves, which are all ternate, and supported upon slender hairy petioles. The leaflets are obcordate, entire, hairy, of a yellowish-green colour, but frequently purplish on their under surface. The scape or flower-stalk, which usually exceeds the petioles in length, is furnished with two scaly bractes near the middle, and terminates in a large white, or flesh-coloured flower, marked with red streaks. The styles are of the same length with the inner stamens.

This plant is a native both of Europe and N. America. In this country it is found chiefly in the mountainous regions of the interior. It selects shady places, such as woods, groves, and hedges; and flowers in May. Other indigenous species of Oxalis, more widely diffused than the *O. Acetosella,* might be substituted for it without disadvantage, as they possess similar properties. They all have ternate leaves with obcordate leaflets, and, with the single exception of the *O. violacea,* bear yellow flowers. The whole herbaceous portion may be used.

Properties. Wood-sorrel is without smell, and has a pleasant sour taste. It owes its acidity to the *binoxalate of potassa,* which is separated for use, and sometimes sold in the shops under the name of the *salt of sorrel.* In England it is mixed with a considerable proportion of bitartrate of potassa, and sold as the *essential salt of lemons.* It comes from Switzerland and Germany, where it is prepared from different species of Oxalis and Rumex. The following process is employed. The plants previously bruised are macerated for some days in water, and then submitted to pressure. The liquid thus obtained is mixed with clay and occasionally agitated for two days. At the end of this time, the clear liquor is decanted, and evaporated so that crystals may form when it cools. These are purified by solution and a new crystallization. Five hundred parts of the plant afford four parts of the acidulous salt. The same salt may be prepared by cautiously dropping a solution of potassa into a saturated solution of oxalic acid. The binoxalate crystallizes when a sufficient quantity of the alkali has been added. It is in rhomboidal crystals, of a sour pungent bitterish taste, soluble in ten times their weight of boiling water, much less so in cold water, and unalterable in the air. It is employed for removing iron mould and ink stains from linen, and sometimes as a test for lime. It contains 72.48 parts or two equivalents of oxalic acid, 47.5 parts or one equivalent of potassa, and 18 parts or two equivalents of water.

Medical Properties. This and other species of sorrel are refrigerant; and their infusion, or a whey made by boiling them in milk, may be used as a pleasant drink in febrile and inflammatory affections. A solution of the binoxalate of potassa is used on the continent of Europe as a substitute for lemonade. The fresh plant, eaten raw, is said to be useful in scorbutic cases. W.

ACETUM. *U. S., Lond., Ed.*

Vinegar.

Off. Syn. ACETUM VINI. *Dub.*

Vinaigre, *Fr.;* Essig, *Germ.;* Aceto, *Ital.;* Vinagre, *Span.*

Vinegar is a sour liquid, the product of a peculiar fermentation called acetous. Viewed chemically, it is a very dilute solution of acetic acid, containing foreign matters. (See *Acidum Aceticum.*)

The acetous fermentation can be induced in all liquors which have undergone or are susceptible of the vinous fermentation. Thus sugar and water, saccharine vegetable juices, infusion of malt, cider, and wine, may be converted into vinegar, if subjected to the action of a ferment, and exposed, with access of air, to a temperature between 75° and 90°.

In different countries, different liquors are used for conversion into vinegar. In France and other wine countries, wine is employed; in Britain, infusion of malt; and in the United States, for the most part, cider. For the use of the white lead manufacturer, it has, of latter years, been extensively made from potatoes.

The method pursued in making wine vinegar at Orleans, in France, where it is manufactured in the greatest perfection, is as follows. Casks are employed of about the capacity of 88 wine gallons, those being preferred which have been previously used for a similar purpose. They are placed upright in three rows, one above another; each cask having an opening at the top of about two inches in diameter. In summer, no artificial heat is used; but in winter, the temperature of the manufactory is maintained at about 68°. The wine intended to be converted into vinegar is kept in separate casks, containing beech shavings, on which the lees are deposited. Twenty-two gallons of good vinegar, boiling hot, are first introduced into each vinegar cask, and at the end of eight days, about two gallons of the wine, drawn off clear, are added; and the same quantity is added every eight days, until the casks are full. After this, the vinegar takes about fifteen days to form. At the end of this time, only half the contents of each cask is drawn off; and it is filled up again by the addition of two gallons of wine every eight days as at first. In some cases, however, the quantity of wine added, and the intervals between the successive additions, are greater or less than those here indicated; the variations in this respect depending upon the progress of the fermentation. To determine this point, the vinegar makers plunge a stave into the cask; and if, upon withdrawing it, they find it covered with froth, they judge that the fermentation is going on properly, and, accordingly, add more wine.

Two sorts of wine vinegar occur in commerce, the white and the red; the former being derived from the acetification of white, the latter, of red wine. Red vinegar, however, may be deprived of its colour and rendered limpid, by being passed repeatedly through animal charcoal.

When the infusion of malt is employed, the process is as follows. The infusion, when properly cooled, is put into large and deep fermenting tuns, where it is mixed with yeast, and kept in fermentation for four or five days. The liquor is now distributed into smaller vessels, placed in a room heated by means of a stove, and kept there for about six weeks, or until the whole is soured. It is then transferred to common barrels, which are placed in the open air, the bung-holes being simply covered with a tile to keep out the rain; in which situation they are allowed to remain for four or five months, or until perfect vinegar has formed. The process is then completed in the following manner. Large tuns are prepared, with false bottoms, on which is put a quantity of the refuse of raisins and other fruit, technically called *rape*. These tuns are worked in pairs, one being completely filled with the vinegar from the barrels, and the other only three-fourths filled. In the latter, the fermentation takes place most readily; and the process is rendered more active alternately in one or the other tun, by filling up each daily from the other, until the process is completed.

In the United States, cider is the principal liquid from which vinegar is prepared. In families, it is made from cider which has become too sour, and from the daily remains of the family consumption. These are put into the vinegar barrel, in a warm place, along with some good vinegar, or with what is called the *mother of vinegar*, that is, the peculiar gelatinous coagulum which forms in this liquid during the progress of the acetous fermentation, and which acts as the ferment. In a few weeks the vinegar will be formed.

When vinegar is made on a large scale from cider, the liquor is placed in barrels with their bung-holes open, which are exposed during the summer to the heat of the sun. The acetification is completed in the course of about two years. The progress of the fermentation, however, must be watched; and as soon as perfect vinegar has formed, it should be racked off into clean barrels. Without this precaution, the acetous fermentation would be followed by the putrefactive, and the whole of the vinegar be spoiled. The early cider is not so good for conversion into vinegar as the late, in consequence of the abundance of malic acid which the former contains; for it must be recollected, that in cider, the malic acid is not the subject matter of the acetous fermentation, but the alcohol which it contains as a vinous liquor.

Vinegar may be clarified, without injuring its aroma, by throwing about a tumbler full of boiling milk into from fifty to sixty wine gallons of the liquid, and stirring the mixture. This operation has the effect, at the same time, of rendering red vinegar pale.

The changes which occur during the acetous fermentation, are not well understood. During its progress, there is a slight disengagement of heat; the liquor absorbs oxygen, becomes turbid, and filaments form, which are observed to move in various directions, until, finally, the fermentation being completed, they are deposited in a mass of a pultaceous consistence. The liquor now becomes transparent, its alcohol is found to have disappeared, and acetic acid to have formed in its place. How then is this change of alcohol into acetic acid effected? From a comparison of the ultimate composition of these two substances, Berzelius supposes that one equivalent of alcohol, absorbs four equivalents of oxygen, three of which are expended in forming water with three equivalents of hydrogen in the alcohol, while the fourth enters into the composition of the acetic acid produced. In this way four equivalents of carbon, six of hydrogen, and two of oxygen (alcohol,) become four equiv. of carbon, three of hydrogen, and three of oxygen (acetic acid.) The carbonic acid, observed to be generated by De Saussure during the acetous fermentation, is considered by Berzelius as a product not of that process, but of the vinous fermentation simultaneously taking place in the liquid, in consequence of the presence of sugar.

It is known with certainty, that alcohol, either pure, or simply diluted with water, will never undergo the acetous fermentation; but if it be properly reduced with water, and mixed with yeast, or some other ferment, acetification will take place. According to Chaptal, if two pints of brandy be carefully mixed with about four drachms of yeast, and a little starch, there will be produced an extremely strong vinegar, which will begin to form about the fifteenth day. Vinegar may also be made by means of the starch and ferment mixed with water, without the alcoholic liquor; but in this case the process will be longer, and the product much weaker.

Acetic acid is not produced exclusively by the acetous fermentation. Thus it is found that sugar, mixed with water in which the gluten of wheat has fermented, will be converted into vinegar, without access of air, and without any appearance of fermentation. The infusion of malt, provided sufficient hops have not been added, becomes sour in the course of a few days; and the same is the case with beer and cider if long kept.

Properties. Vinegar, when good, is of an agreeable penetrating odour, and pleasant acid taste. Its colour varies from pale yellow to deep red. When long kept, particularly if exposed to the air, it becomes muddy and ropy, acquires an unpleasant smell, putrefies, and loses its acidity. This result may, in a good measure, be prevented by boiling it for a few minutes, so as to coagulate and separate the gluten, and immediately transferring it to bottles, which must be well corked.

The essential parts of vinegar are *acetic acid* and *water*, in the proportion of about five parts of the former to ninety-five of the latter; but besides these it contains various other substances, derived from the particular vinous liquor from which it may have been prepared. Among these may be mentioned, colouring matter, gum, starch, gluten, sugar, a little alcohol, and frequently malic and tartaric acid, with minute portions of alkaline and earthy salts. It is sometimes intentionally adulterated with sulphuric, muriatic, or nitric acid. Sulphuric acid may be detected by acetate of baryta, which throws down sulphate of baryta, distinguishable from the malate and tartrate of the same base by its insolubility in nitric acid. Muriatic acid is shown by a precipitate being formed by nitrate of silver, insoluble in nitric acid, but perfectly soluble in water of ammonia. To detect nitric acid, add a little common salt, saturate by adding carbonate of potassa, and evaporate to dryness. Upon the dry residue, pour equal parts of sulphuric acid and water, through which some gold leaf has been diffused, and boil the mixture. If nitric acid be present, nitro-muriatic acid will be generated, in consequence of the decomposition of the common salt, and the gold leaf will be dissolved.

English malt vinegar always contains sulphuric acid. According to Mr. Phillips, the strongest vinegar of this kind is called *proof vinegar*, and is distinguished by the manufacturer as No. 34. It is estimated to contain five per cent. of real acid, and the maker is allowed to mix with it one-thousandth of its weight of sulphuric acid. In testing this vinegar for impurities, allowance should be made for this proportion of sulphuric acid, equivalent to one grain and a fifth of sulphate of baryta to the fluidounce.

Sometimes grains of paradise, spurge flax, capsicum, or pellitory of Spain, are added to vinegar to give it more pungency. When present, they can be detected by the taste.

Vinegar is rendered aromatic by various additions; such as citron, thyme, and rosemary. Henry's aromatic vinegar is an acetic solution of camphor, and of the oils of cloves, lavender, and rosemary. The Edinburgh College have a preparation of this kind under the name of *Acidum Aceticum Aromaticum*, to which head the reader is referred.

Medical Properties. Vinegar acts as a refrigerant and diuretic. With this view, it is added to diluent drinks in inflammatory fevers. It is useful in affections of the urinary organs, attended with a white deposition from the urine, consisting of phosphate of lime and phosphate of magnesia and ammonia. It is sometimes used as a clyster, diluted with twice or thrice its bulk of water. It has been supposed to be a powerful antidote to the narcotic poisons, but this is a mistake. In the case of opium the best authorities unite in considering it worse than useless, as it rather gives activity to the poison than neutralizes it. Externally it is employed as a fomentation or lotion in bruises and sprains. Diluted with water, it forms the best means of clearing the eye from small particles of lime. Its vapour is inhaled in certain states of sorethroat; and is diffused through sick rooms under the impression that it neutralizes pestilential effluvia, though in fact it has no other effect than to cover unpleasant smells. The dose is from one to four fluidrachms; as a clyster from one to two fluidounces.

ACIDUM ACETICUM EMPYREUMATICUM. *U.S.*

Pyroligneous Acid.

"Acidum aceticum impurum, ex ligno destillatum. *Impure acetic acid, obtained from wood by distillation.*" *U.S.*

Acide pyro-ligneux, *Fr.;* Brenzliche Holzsäure, *Germ.;* Acido pyrolignico, *Ital.*

This is the impure acetic acid obtained from wood by destructive distillation in close vessels. Wood, when charred, yields many volatile products, among which are an acid liquor, empyreumatic oil, and tar containing creosote and some other newly discovered proximate principles. When the carbonization is performed in close vessels, these products, which are lost in the ordinary process of charring, may be collected, and at the same time, a larger amount of charcoal obtained. The acid liquor, when freed as far as possible by rest from the tar and oil, is the pyroligneous acid.

Carbonization in close vessels, with a view to preserve the volatile products, was first put in practice by Mollerat at Nuits in France. The apparatus employed at Choisy, near Paris, is thus described by Thenard. It consists of, 1st, a furnace with a moveable top; 2d, a strong sheet-iron cylinder, sufficiently capacious to contain a cord of wood, and furnished with a sheet-iron cover; 3d, a sheet-iron tube proceeding horizontally from the upper and lateral part of the cylinder to the distance of about a foot; 4th, a copper tube connected with the last, which is bent in such a manner as to plunge successively to the bottom of two casks filled with water, and after rising out of the second, is then bent back, and made to terminate in the furnace. At the bottom of each cask, the tube dilates into a ball, from the under part of which another tube proceeds, which, passing water-tight through the cask, terminates over a vessel, intended to receive the condensible products.

The sheet-iron cylinder, being filled with wood, and closed by luting on its cover with fire-clay, is let down into the furnace by the help of a crane. The fire is then applied, and when the process is completed, the cylinder is removed by the same means, to be replaced by another. During the carbonization, the volatile products pass off by the tube; and those which are condensible, being the pyroligneous acid and tar, are condensed by the water in the casks, and collect in the lower bends of the tubes, from which they run into the several recipients; while the incondensible products, being inflammable gases, are emitted finally in the furnace, where, by their combustion, they assist in maintaining the heat. Eight hundred pounds of wood afford, on an average, thirty-five gallons of crude acid, weighing about three hundred pounds.

Properties. Pyroligneous acid is a brown transparent liquid, having a strong smoky smell. It consists essentially of acetic acid, diluted with more or less water, and holding in solution tar and empyreumatic oil. It may be purified by chemical means, and furnishes a strong acetic acid, which is officinal with the London College under the name of *Acidum Aceticum Fortius.* In its purified state it is sometimes used in the manufacture of white lead. In the extensive lead works of the Messrs. Lewis, of Philadelphia, pyroligneous acid is made on a large scale, after the French method, with a view to its subsequent purification and employment in the manufacture of this article.

Medical and Economical Properties. Pyroligneous acid, in a dilute state, has been used as an application to gangrene, and ill-conditioned ulcers. It acts on the principle of an antiseptic and stimulant, the former property being probably due to the presence of creosote. Several cases in which it was successfully employed, are reported in a paper by Dr. T. Y. Simons, of Charleston, S. C. published in the fifth volume of the American Journal of Medical Sciences.

This acid is advantageously applicable to the preservation of animal food. Mr. William Ramsay, (*Edin. Phil. Journ.* iii. 21.) has made some interesting experiments on its use for this purpose. Herrings and other fish, simply dipped in the acid and afterwards dried in the shade, were effectually preserved, and when eaten, were found very agreeable to the taste. Herrings slightly cured with salt, by being sprinkled with it for six hours, then drained, next immersed in pyroligneous acid for a few seconds, and afterwards dried in the shade for two months, were found by Mr. Ramsay to be of fine quality and flavour. Fresh beef, dipped in the acid in the summer season for the short space of a minute, was perfectly sweet in the following spring. Professor Silliman states, that one quart of the acid added to the common pickle for a barrel of hams, at the time they are laid down, will impart to them the smoked flavour as perfectly as if they had undergone the common process of smoking. B.

ACIDUM ARSENIOSUM. *U.S.*

Arsenious Acid.

Off. Syn. ARSENICUM ALBUM. *Lond.;* OXIDUM ARSENICI, *Ed.;* ARSENICI OXYDUM ALBUM. *Dub.*

White Arsenic; Acide arsenieux, Arsenic blanc, *Fr.;* Arsenichte Säure, Weisser Arsenik, *Germ.;* Arsenik, *Dan.*, *Swed.*, *Polish;* Acido arsenioso, Arsenico, *Ital.;* Arsenico blanco, *Span.*

The basis of all the arsenical preparations is a peculiar metal called arsenic. It is brittle and of a steel-gray colour, and possesses much brilliancy when recently broken or sublimed. Exposed to the air, its surface becomes dull and blackens. Its texture is granular, and sometimes a little scaly. Rubbed in the hands it communicates a peculiar odour, but it is devoid of taste. Its sp. gr. is 5.7 according to Berzelius, 5.9 according to Guibourt. When heated to about 356° of Fahr. (*Berzelius*) it sublimes without fusing, giving rise to vapours having an alliaceous or garlicky odour. Its subliming point is differently stated by Dr. J. K. Mitchell and Mr. Durand. According to these experimenters, this point is as high as a red heat visible in the dark. (*Journ. Phil. Col. of Pharm.* iv. 108. *July*, 1832.) Its equivalent number is 37.7.

Arsenic forms two well characterized combinations with oxygen, both having acid properties, called *arsenious* and *arsenic acid*.

Preparation, &c. Arsenious acid is prepared chiefly in Bohemia and Saxony, where it is procured on a large scale, as a collateral product, during the smelting of cobalt ores, which are almost invariably accompanied by arsenic. These ores are roasted in reverberatory furnaces, with long horizontal flues. The arsenic is converted, by combustion, into arsenious acid, which sublimes and condenses on the sides of the flues. In this state it is not pure, and requires a second sublimation, which is performed in cast iron vessels, fitted with conical heads of the same material, having an opening at the summit. The vessels are placed over a furnace, and brought to a red heat, when a portion of the impure arsenious acid is thrown in through the opening, which is immediately stopped. This portion being sublimed, a new portion is introduced in a similar manner. Finally the vessels are allowed to cool, and the heads being removed, the purified acid is found attached to them in vitreous layers, at first as transparent as glass, but gradually becoming, by contact with the air, opaque at their surface. These are broken up in fragments of a convenient size, and thrown into commerce. The arsenious acid which reaches this country is generally packed in casks, containing from two to five hundred pounds, and is shipped principally from the ports of Hamburg and Bremen.

Properties. Arsenious acid, as it occurs in commerce, is in masses exhibiting a vitreous fracture. It is of a milk-white colour exteriorly, but internally, perfectly transparent. As first sublimed, the whole mass is transparent, but it gradually becomes white and opaque, the change proceeding progressively from the surface inwards. The nature of this change has not been well determined. According to Guibourt, the sp. gr. of the transparent variety is 3.73; that of the opaque, 3.69. The experiments, however, of Dr. Mitchell and Mr. Durand make the density of the former variety from 3.208 to 3.333. As it occurs in the shops for medicinal use, it is in the form of a white powder, almost as fine as flour. In this state it is sometimes adulterated with powdered chalk, or sulphate of lime, a fraud which is easily detected by exposing the powder to a heat sufficient to evaporate the arsenious acid, when these impurities will be left behind. It is erroneously stated to have an acrid taste. Dr. Christison asserts that it possesses hardly any taste, inasmuch as it produces merely a faint sweetish impression on the palate. In strong, hot solution, it has an austere taste, most nearly resembling that of sulphate of zinc. (*Mitchell and Durand.*) It has no smell even when in a state of vapour; as the garlicky odour, which is sometimes attributed to it, belongs only to the vapours of the metal; and when apparently arising from the acid itself, is, in fact, owing to its reduction. Its point of sublimation, according to Berzelius, is at an incipient red heat; but according to Mitchell and Durand, it is lower instead of higher than that of metallic arsenic, being only 425° of Fahr. When sublimed slowly, it condenses in regular octohedral crystals, exhibiting a strong lustre. It consists of two equivalents of arsenic 75.4, and three equivalents of oxygen $24=99.4$.

Arsenious acid is soluble in water. Guibourt states that its solubility differs according as it is transparent or opaque. Thus 1000 parts of water at 69° Fahr. dissolve 9.6 of the transparent, and 12.5 of the opaque variety; and the same quantity of boiling water dissolves 97 parts of the transparent, retaining 18 when cold, and 115 parts of the opaque, retaining 29 on cooling. These results show that a boiling saturated solution, when allowed to cool, retains more of the acid in solution, than can be dissolved in cold water without a preliminary boiling, and teach the propriety of employing a boiling temperature when searching for this mineral. The solubility of the powder of arsenious acid, as prepared for use in medicine, corresponds, of course, with that of the opaque variety.

Medical Properties. Internally, the action of the preparations of arsenic is alterative and febrifuge; externally, for the most part, violently irritant. They have been considered as peculiarly applicable to the treatment of diseases of a periodical character. When commencing their exhibition, the dose should be small, and afterwards gradually increased, its operation being carefully watched. When the specific effects of the medicine are produced, it must be immediately laid aside. These are, a general disposition to œdema, especially of the face and eyelids, a feeling of stiffness in these parts, itching of the skin, tenderness of the mouth, loss of appetite, and uneasiness and sickness of the stomach. The peculiar swelling produced is called *œdema arsenicalis.* The principal preparations now in use are the arsenious acid, the article under consideration, and the solution of arsenite of potassa, or Fowler's solution. The arseniates of potassa and soda, and the sulphuret of arsenic are also occasionally employed. One grain of the arseniate of soda, dissolved in a fluidounce of water, forms the *arsenical solution of Pearson.*

It may be a question whether the different arsenical preparations act precisely in the same way, when exhibited internally. It is supposed by some, that the selection need only be regulated by the convenience for exhibition. Dr. Physick, whose opinion is entitled to great respect, thinks otherwise; for, with regard to the arsenious acid, and the solution of arsenite of potassa, (Fowler's solution,) the result of his experience is, that they act differently, and cannot be substituted for one another.

Some writers have entirely proscribed the use of the arsenical preparations in medicine. Amongst these, one of the most authoritative is Mr. Brande, who considers their introduction into the Pharmacopœias a great evil, as affording facilities, by legalizing the medicinal use of the poison, for its employment for self-destruction and murder. At the same time he believes that more harm than benefit has resulted from its administration. (*Man. of Pharm.* p. 29.) We confess, however, that we do not share these opinions with Mr. Brande. Arsenic is confessedly a virulent poison, and is frequently employed for criminal purposes; but when it is considered how extensively it is used in the arts, it is questionable whether its exclusion from the materia medica would much lessen the facility of obtaining it. On the other hand, it may be asked, are poisons more dangerous as medicines than other medicinal substances, if given in their appropriate doses? We should think not; though we freely acknowledge, that dangerous mistakes in the dose are more apt to occur. If the views of Mr. Brande were carried out, they would lead to the discarding of the corrosive chloride of mercury, hydrocyanic acid, strychnia, and other articles from the materia medica; but we believe that no practitioner will be found willing to strike these substances from the list of remedies.

While we wish to retain arsenic as a potent remedy in the hands of the judicious practitioner, we should be glad to find the public authorities in the United States subjecting the sale of this poison to strict regulations, under heavy penalties for their infraction. Speaking of the practice in Europe, Berzelius remarks, "Le commerce de l'acide arsénieux est toujours soumis a une surveillance sévère, et l'achat n'en est permis qu'a ceux, qui ont donné des preuves légales qu'il leur est indispensable dans l'exercise de leur état. A l'exception de ces cas, l'acheteur et le vendeur sont soumis a une responsabilité très sévère." (*Traité de Chimie*, ii. 431.)

Arsenic has been exhibited in a great variety of diseases, the principal of which are scirrhus and cancer, especially cancer of the lip; anomalous ulcers; intermittent fever; chronic rheumatism, particularly that form of it attended with pains in the bones; diseases of the bones, especially nodes; frontal neuralgia; and different painful affections of the head, known under the names of hemicrania and periodical headache. It has been extolled as a remedy in certain cutaneous affections, particularly lepra. Cases of its efficacy in several of these diseases will be mentioned here, while its effects in other complaints will be noticed under the article *Liquor Potassæ Arsenitis*, to which the reader is referred. Its external application has been principally restricted to cancer, and anomalous and malignant ulcers, especially of that kind denominated *noli me tangere*. For a complete list of the diseases in which arsenic has been tried, the reader is referred to Mr. Hill's paper in the Edin. Med. Journal, vols. v. and vi.

Justamond considered arsenic as a specific in cancer, but subsequent experience has not justified his opinion. This metal, however, is thought highly of by many practitioners in cases of lupus, and ill-looking sores of the face, lips, and tongue, and often effects a cure.

Arsenic is the chief ingredient in nearly all the empyrical remedies for the cure of cancer by external application. Plunket's caustic was a secret remedy of this kind, of great celebrity, and consisted of the Ranunculus acris and Ranunculus Flammula, each an ounce, bruised, and mixed with a drachm of arsenious acid, and five scruples of sulphur. The whole was beaten into a paste, formed into balls, and dried in the sun. When used, these balls are rubbed up with yolk of egg, and spread on pig's bladder. The use of the vegetable matter is to destroy the cuticle; for unless this is done, the arsenic will not act. Mr. Samuel Cooper thinks this caustic was never of any permanent benefit in genuine cancer, but has effected perfect cures in some examples of lupus, and malignant ulcers of the lips and roots of the nails.

The late Dr. Rush, (*Trans. Am. Phil. Soc.* ii. 212,) has given an account of the cancer powder of a certain Dr. Hugh Martin, who was surgeon to one of the Pennsylvania regiments during the American Revolution. Dr. Rush had witnessed its application in several cases, and bears testimony to its having performed complete cures in several cancerous ulcers, mostly seated on the nose or cheeks; but where the disease was much connected with the lymphatic system, or with scrofula, it always failed. Upon the death of Dr. Martin, Dr. Rush obtained some of the powder, and having subjected it to analysis, found its active ingredient to be arsenious acid, in the proportion of about one-fortieth of the whole powder. The remainder was vegetable matter, and, in the specimen which Dr. Rush experimented upon, consisted of belladonna. The powder in question gave less pain than the nitrate of silver, and seldom produced an eschar, but only moderate inflammation; the vegetable matter with which the arsenious acid was mixed mitigating the violence of its action. Dr. Martin sometimes touched the ulcers with a feather, dipped in a liquid, which was probably a solution of arsenious acid.

At Paris, an arsenical paste of the following composition is used as an application to malignant ulcers:—Red sulphuret of mercury 70 parts; dragon's blood 22 parts; arsenious acid 8 parts. It is applied, made up into a paste with saliva. The pain produced by this composition is very severe, and its application dangerous. The practice of sprinkling unmixed arsenious acid on ulcers is now reprobated, as fraught with the greatest danger. Mr. S. Cooper characterizes it as a murderous practice. It may, however, be used either in solution, or reduced by some mild ointment. A lotion may be formed with eight grains of arsenious acid and the same quantity of carbonate of potassa, dissolved in four fluidounces of distilled water; and a cerate, with one drachm of arsenious acid and twelve drachms of simple cerate. The arsenic cerate of the U. S. Pharm. is only of half this strength. (See *Ceratum Arsenici.*) The lotion is in effect a solution of arsenite of potassa.

Febure's remedy for cancer consisted of ten grains of arsenious acid dissolved in a pint of distilled water, to which were added an ounce of extractum conii, three fluidounces of liquor plumbi subacetatis, and a fluid drachm of tinct. opii. With this the cancer was washed every morning. Febure's formula for internal exhibition was, arsenious acid two grains; rhubarb half an ounce; syrup of chicory, q. s.; distilled water a pint. Of this mixture, a tablespoonful, which contained about a twelfth of a grain of the acid, was given every night and morning, with half a fluid drachm of the syrup of poppies. The dose was gradually increased to six tablespoonfuls.

Arsenious acid may also be given in pills. A convenient formula is to mix one grain of the acid with ten grains of sugar, and to beat the mixture with crum of bread, so as to form a pilular mass, to be divided into ten pills, one of which is a dose.

Properties of Arsenious Acid as a Poison. Arsenious acid, in an overdose, administered internally, or applied externally, acts with very great energy, and generally destroys life in a short time. The symptoms it produces are an austere taste; fetid state of the mouth; frequent ptyalism; continual hawking; constriction of the pharynx and œsophagus; the sensation of the teeth being on edge; hickups; nausea; anxiety; frequent sinkings; burning pain at the precordia; inflammation of the lips, tongue, palate, throat, and œsophagus; irritable stomach, so as not to be able to support the blandest drinks; vomiting of matters, sometimes brown, at other times bloody; black, horribly fetid stools; pulse small, frequent, concentrated, and irregular, occasionally slow and unequal; palpitations; syncope; insatiable thirst; burning heat over the whole body, or a sensation of icy coldness;

difficult respiration; cold sweats; scanty, red, and bloody urine; change in the countenance; a livid circle round the eye-lids; swelling and itching of the body; livid spots over the surface, and occasionally a miliary eruption; prostration of strength; loss of feeling, especially in the feet and hands; delirium; convulsions, often accompanied with insupportable priapism; falling off of the hair; detachment of the cuticle, &c. It is very rare to observe all these symptoms in the same individual. In some cases, indeed, they are nearly all wanting, death taking place without any pain or prominent symptom. After death, the morbid appearances are various. In some cases, no vestige of lesion can be discovered. The appearances, however, in the generality of cases, are the following. The mouth, stomach, and intestines are inflamed; the stomach and duodenum exhibit spots resembling eschars, and perforations of all their coats; and the villous coat of the former is in a manner destroyed, and reduced to the consistence of a reddish-brown pulp.

Dr. Christison divides the poisonous effects of arsenious acid into three orders of cases, according to the character and violence of the symptoms. In the first order, the poison produces symptoms of irritation and inflammation along the course of the alimentary canal, and commonly kills in from one to three days. In the second, the signs of inflammation are moderate, or even altogether wanting, and death occurs in five or six hours, at a period too early for inflammation to be always fully developed. In the third order of cases, two stages occur, one in which inflammatory symptoms are developed, as in the first order; the other, marked by symptoms referrible to nervous irritation, such as imperfect palsy of the arms or legs, epilepsy, tetanus, hysterical affections, mania, and coma. It is a general character of this poison to induce inflammation of the stomach in almost all instances, provided death does not take place immediately, whatever be the part to which it is applied. Thus the poison, when applied to a fresh wound, will give rise to the same morbid appearances in the stomach and intestines, as when it is swallowed. In some cases, observed by Drs. Mall and Bailie, the rectum was much inflamed, while the colon and small intestines escaped.

The precise rank which should be assigned, in the scale of poisons, to arsenious acid when applied externally, is still undetermined. One set of observers contend that its external application is not attended with great danger, while another party conceives that it acts as a virulent poison. Hunter, Sir Everard Home, Jœger, Brodie, Dr. Campbell of Edinburgh, Smith, and Orfila, have all adduced experiments on the inferior animals, which prove that arsenious acid, inserted into a recent wound, causes death after a longer or shorter period. Indeed, some observations prove that the poisonous effects of the substance are developed in a smaller dose, when used in this way, than when taken into the stomach. Nor are there wanting many well authenticated facts of its deleterious effects on the human constitution. Roux reports the case of a young woman under his care, whose death was caused, after agonizing sufferings, by the application of an arsenical paste to a cancerous breast. Sir Astley Cooper, in his lectures, bears testimony to the dangerous effects of arsenic externally applied. On the other hand, some writers contend for the safety of the external application of this poison. Mr. Blackadder applied it in large quantities to sores, and never witnessed a single instance in which it acted constitutionally. Dr. Randolph of Philadelphia, (*North Amer. Med. and Surg. Journ.* v. 257,) states that Dr. Physick informed him, that though he had frequently and successfully employed arsenic by external application, he had never, in the whole course of his practice, seen it productive of the injurious consequences which have been attributed to it. In weighing such conflicting testimony, we are constrained to believe, that the circumstances of the different experiments and observations must have been different; and we think that the observations of Blackadder and Harles point out in what this difference consists. It seems to depend entirely on the circumstances of the application, as being favourable or unfavourable to absorption. Blackadder attributes his very success to the large quantities of the arsenic which he employs; and which, he contends, kills the part without being absorbed; and this is probably the fact. Harles's observations may be explained on the same principle. He contended that the outward application of arsenic is comparatively safe to ulcers, either common or malignant; but is dangerous to parts recently wounded and pouring out blood. Here the difference would seem to consist in the greater liability to absorption in the latter than in the former case. The very dilution caused by the blood, may be an efficient promoter of absorption, and is entirely consonant with the experiments of Dr. Campbell, who found that arsenic acted with more energy, when dissolved in water, than in the solid state. The case in which Dr. Randolph employed this mineral, by the advice of Dr. Physick, was one of ulcerated scrotum, in which it acted by producing the death of the diseased part, a state evidently unfavourable to absorption. The formula employed was one part of the arsenious acid to five parts of the flowers of sulphur.

Arsenious acid, when it produces the death of a part, does not act, strictly speaking, as an escharotic. It destroys the vitality of the organized structure, and its decomposition is the consequence. The true escharotic acts chemically by decomposing the part to which it is applied, inducing a change incompatible with its life. This distinction being preserved, we can explain why the operation of the arsenious acid is often limited to the destruction of diseased formations, which are known to possess a feeble vitality; while the true escharotics destroy both the diseased and healthy structure. When the arsenious acid succeeds as an external application to cancers, which is a very rare occurrence, it acts on this principle; destroying the vitality of the whole diseased portion, and causing it to be thrown off as something foreign to the system.

Upon the whole, new facts are wanting to clear up this difficult subject. Judging from the lights we possess, the external application of arsenious acid, in case it is absorbed, is attended with very great danger; and the conditions of a part and of the system at large, favourable or otherwise to absorption, are too little understood, to make it warrantable to use this poison externally without the greatest caution.

Treatment of Poisoning by Arsenious Acid. Several antidotes have been recommended for arsenious acid. Magnesia, proposed by Mr. Hume, and charcoal by M. Bertrand, are not found on further observation to be entitled to this character. Three cases are on record of recoveries after the use of large doses of magnesia; but it is more than probable that collateral circumstances contributed to the cure. With regard to charcoal, Orfila has proved, that, whatever may be its powers when swallowed mixed with arsenious acid, it has no effect when taken after the ingestion of the poison. The hydrated peroxide of iron, *freshly* prepared, was announced in 1834 by Dr. Bunsen, of Gottingen, as an antidote for arsenious acid, and its efficacy has been confirmed by MM. Orfila and Lesueur, and MM. Soubeiran and Miquel, by a number of experiments on inferior animals. It acts by producing with the poison, the insoluble, and therefore inert arsenite of iron. The antidote is prepared by treating a boiling solution of crystallized sulphate of iron (green vitriol,) with nitric acid, so long as orange fumes are given off, diluting and filtering the liquor, and then precipitating it by an excess of ammonia. The alkali throws down the hydrated peroxide as a reddish precipitate which must be carefully washed. It is essential to its efficacy, that the oxide should be administered in its pulpy and recent state, and in a dose at least twelve times as great as the amount of the poison supposed to be taken; but as the antidote is perfectly innocent in itself, it is prudent to give it in much larger quantities. Its efficacy is of course greater, the sooner it is administered after the ingestion of the poison; but even after delay, its use will prove advantageous, so long as there is reason to believe that any of the poison still remains in the stomach. (*Journ. de Pharm.* t. xxi. p. 98.)

The antidote above mentioned having been faithfully applied, the medical treatment will consist in the administration of mucilaginous drinks. Should the patient survive long enough for inflammatory symptoms to arise, these should be combated on the general principles for treating inflammation. Accordingly, venesection and leeches may become necessary; and in the course of the treatment, emollient enemata, antispasmodics, and narcotics will often prove useful in allaying pain and nervous irritation. Convalescence is generally long and distressing, and hence it becomes of the greatest importance to attend to the diet, which should consist exclusively of milk, gruel, cream, rice, and similar bland articles.

Reagents for detecting Arsenious Acid. As arsenic is so frequently employed for criminal purposes, or self-destruction, it becomes of importance to detect its presence in medico-legal investigations. The tests for this poison may be divided into, 1. Those which indicate indirectly its presence; and, 2. Those which demonstrate its presence incontestibly, by bringing it to the metallic state. The former embrace all the liquid reagents, so called; the latter the different processes for metallization.

The most characteristic reagents, according to Dr. Christison, are *sulphuretted hydrogen*, *ammoniacal nitrate of silver*, and *ammoniacal nitrate of copper*. In the opinion of this writer, the concurrent indications of these three tests are all-sufficient for detecting in an infallible manner the presence of arsenious acid; but we think that in questions involving life and death, it is best to make assurance doubly sure, and, therefore, that the metallization of the poison ought never to be omitted.

In using sulphuretted hydrogen, the solution must be neutral. An excess of alkali may be neutralized with acetic acid; and an excess of nitric or sulphuric acid, by potassa. A slight excess of acetic acid is not, however, hurtful; on the contrary, it rather favours the subsidence of the precipitate, which is of course sulphuret of arsenic. According to Dr. Christison, this test is so exceedingly delicate, that it detects the poison, when dissolved in one hundred thousand parts of water. The colour it produces is lemon or sulphur-yellow; but the presence of vegetable or animal matter commonly changes it to a whitish or brownish tint. Some medical jurists recommend the use of sulphuretted hydrogen water; but the gas is far preferable. It can be applied with much convenience by using one of Dr. Hare's self-regulating gas reservoirs.

Dr. Christison has shown, that how delicate soever the ammoniacal nitrate of silver may be in ordinary solutions, it is not to be depended upon in dilute solutions of this poison, where animal or vegetable matter is present; for the precipitate is either not formed, in consequence of the organic principles exerting a solvent power over it, or, if formed, is essentially altered in colour.

The ammoniacal sulphate of copper is a test of very great delicacy. The precipitate occasioned by it is the arsenite of copper, of an apple-green or grass-green colour. Its operation is prevented by muriatic, nitric, sulphuric, acetic, citric, and tartaric acids in excess; as also by ammonia. But a greater objection to it is, that its indications fail when animal or vegetable matter is present, in case the arsenic is not abundant.

Of the three tests mentioned, perhaps the sulphuretted hydrogen is the most delicate; and it has the advantage of yielding a precipitate eligible for subsequent reduction. But they are all liable to the objection of being obscured in their indications, where the amount of poison is minute, by the presence of organic principles; a complication which constitutes the most difficult problem which can be presented to the attention of the medical jurist. As this case includes all others of more easy solution, we shall suppose it presented to the medical chemist, and shall indicate the steps which are to be pursued.

Having obtained general indications of the presence of arsenic, the first step will be to separate the organic matters; the second, to throw down the arsenic by means of sulphuretted hydrogen; and the third, to reduce the precipitate obtained.

The following are the directions laid down by Dr. Christison for separating the organic principles. Boil the suspected matter with distilled water for half an hour, and filter, first through gauze to separate the coarser particles, and afterwards through paper. To the transparent solution thus obtained, add acetic acid, which will coagulate some animal principles. To ascertain whether the solution has been sufficiently freed from animal matter by this measure, neutralize with ammonia, and test a small portion of it with the ammoniacal nitrate of silver. If this gives a characteristic precipitate, the solution is sufficiently deprived of animal matter; if not, another measure must be adopted to separate it. This consists in first rendering the solution neutral or slightly alkaline, next faintly acidulating with muriatic acid, and then adding an excess of nitrate of silver. This salt precipitates the animal matter in combination with oxide of silver. After this step, the excess of silver is thrown down by a slight excess of chloride of sodium, (common salt,) and the solution filtered.

Having in this manner disembarrassed the solution from organic matter, the free nitric acid is neutralized by potassa in slight excess, and the solution acidulated with acetic acid. A stream of sulphuretted hydrogen is then passed through it, which will throw down the arsenic as a sulphuret. If the proportion of arsenic be very small, a yellowness only will be produced, owing to the precipitate being soluble in an excess of the precipitant. In this case it is necessary to boil, to drive off the excess of sulphuretted hydrogen. The precipitate is then collected and dried. If it be very minute, it must be allowed to subside, and the supernatant liquid having been withdrawn, the remainder is to be poured upon a filter. After filtration, the precipitate is washed down to the bottom of the filter by means of the instrument called a *pipette*, employed for washing scanty precipitates. The filter is then gently pressed between folds of bibulous paper, and the precipitate removed with the point of a knife before it dries, and then dried in little masses on a watch-glass. In this manner Dr. Christison states that it is easy to collect so small a portion of the sulphuret as the twenty-fifth part of a grain. The precipitate is then to be reduced by means of a flux, which this author recommends to consist of two parts of ignited carbonate of soda and one of charcoal, as preferable to black flux. The best flux for the arsenious acid is freshly ignited charcoal.

A method different from that of Dr. Christison has been recommended by M. Taufflier for separating organic substances. It consists in adding to the mucilaginous liquid, resulting from the decoction of the suspected matters, a solution of oxide of zinc in potassa. The oxide precipitates in union with the organic substances, while the potassa unites with the arsenious acid and remains in solution. The clear solution, obtained by decantation or filtration, being then acidulated with muriatic acid, the arsenic is precipitated by sulphuretted hydrogen, as recommended by Dr. Christison. (*Journ. de Pharm.* xx. 392.)

The general formula for reduction is as follows. The operation is performed in a small glass tube. If the matter to be operated on is small, it is introduced to the bottom of the tube, and then a little of the flux is added to cover it, care being taken that the materials are conducted to the place they are to occupy, by means of a small glass funnel with a slender stem, without soiling the empty part of the tube. The heat is to be applied by means of a spirit lamp, the upper part of the material being first heated with a small flame, and afterwards the lower part with a larger flame. A little water, disengaged at first, should be removed with a roll of filtering paper, before sufficient heat has been applied to sublime the metal. When the dark crust begins to form, the tube should be held quite steady, and in the same part of the flame. This crust is the metallic arsenic, having the surface next the tube resplendent and polished, and the interior surface crystallized. Its characters are quite distinct, even when it does not amount to more than the three-hundredth part of a grain.

ACIDUM CITRICUM. *U.S.*, *Lond.*, *Dub.*

Citric Acid.

Off. Syn. ACIDUM CITRICUM CRYSTALLIZATUM. *Ed.*

Acidum limonis; Acide citrique, *Fr.;* Citronensäure, *Germ.;* Acido citrico, *Ital.*, *Span.*

Citric acid is the peculiar acid to which limes and lemons owe their acidity, being found in greatest abundance in the former. It is present also in the juice of other fruits, though in smaller amount; such as the European cranberry, (Vaccinium Oxycoccus,) the red whortelberry, (Vaccinium Vitis idæa,) the berry of the bittersweet, (Solanum Dulcamara,) the red gooseberry, (Ribes Grossularia,) the garden currant, (Ribes rubrum,) the strawberry, (Fragaria vesca,) the raspberry, (Rubus idæus,) and the tamarind, (Tamarindus Indica.)

The acid is extracted from lemon or lime juice by a very simple process, for which we are indebted to Scheele. The juice is imported into the United States from the West Indies, principally from the Island of Cuba, for the purpose of being converted into syrup, or manufactured into citric acid. To obtain the acid, the juice is first completely saturated by carbonate of lime, (chalk or whiting,) in fine powder, and the citrate of lime formed is allowed to subside. This is then washed repeatedly with water, and decomposed by diluted sulphuric acid. An insoluble sulphate of lime is immediately formed, and the citric acid, being separated, remains in the supernatant liquor. This is carefully concentrated in leaden boilers, until a pellicle begins to form, when it is transferred to other vessels in order to cool and crystallize. As the crystals obtained by the first crystallization are generally brown, they require to be redissolved and recrystallized for several successive times, in order to render them pure and white.

Mr. Parkes, in his Chemical Essays, has given a very interesting account of the manufacture of citric acid, which is made in large quantities in London for the use of the calico-printers. As Mr. P. was himself engaged in this manufacture, the following outline of the process which he pursued, may be received with greater confidence. The juice is placed in large square vats, in which it is saturated with clean soft chalk or whiting, gradually added to prevent excessive effervescence. The insoluble citrate of lime is allowed to subside, and the supernatant liquid, containing mucilage, saccharine matter, and a little malic acid, is drawn off by means of a syphon. The citrate is then passed through a sieve, and washed with warm water, until all remaining mucilage, and other soluble impurities are removed. It is then decomposed, while yet moist, by means of sulphuric acid, taken in the proportion of nine pounds and a half of the strong acid diluted with seven gallons of water, for every ten pounds of chalk used in the saturation. Some deduction, however, may be made from the water of dilution, in consideration of the water present in the moist citrate. The quantity of chalk expended may be easily ascertained by weighing out more than is sufficient for the purpose of saturation, and weighing the remainder after the point of saturation shall have been attained. The sulphuric acid is gradually poured in immediately after the water has been added to it, in order that the decomposition may be assisted by the heat generated by its dilution; and at the same time, the whole is well stirred with a strong wooden spatula, in order to prevent the citrate from running into lumps and thus escaping the action of the acid. As the point of complete decomposition of the citrate approaches, the sulphate of lime precipitates more and more quickly, and the quantity of supernatant liquid becomes sensibly greater. When the decomposition has been completed, the solution of citric acid is drawn off, and the sulphate of lime washed repeatedly with *cold* water, to separate any remains of acid. The solution of the acid, together with the washings, is then concentrated by evaporation in leaden boilers, until it reaches the sp. gr. of about 1.130; when the fire is to be withdrawn and the acid removed to a smaller leaden vessel, where it undergoes a further concentration by means of a water-bath. When the bulk of the acid liquor becomes very much reduced by evaporation, it requires to be transferred to a still smaller leaden boiler, where it is further evaporated by the same means, until the liquor acquires the consistence of very thin molasses. It is then watched with the greatest attention for noting the production of a pellicle, upon the appearance of which over the whole surface of the liquor, the acid is to be deemed sufficiently concentrated, and must be immediately removed from the water-bath, and laid aside to cool and crystallize. If at this stage of the process the removal of the acid were neglected, the whole would be in danger of being carbonized and spoiled.

The liquor is allowed to remain at rest four days, that crystals may be formed, from which the mother waters, presenting a black colour, are to be drained. These are then diluted with ten or twelve times their bulk of water, saturated anew by means of carbonate of lime, and treated in all respects as if they consisted of fresh lemon juice. By this proceeding, a new crop of crystals will be obtained.

Whatever care may be taken in conducting the process, the first crop of crystals will be of a light brownish colour; but if the solution has been burnt during the evaporation, or the mucilage imperfectly separated, they will be dark brown or black. In order to have the crystals perfectly pure and white, it is necessary to subject them to repeated solutions and crystallizations. According to Mr. Parkes, a gallon of good juice, if the process be well conducted, will yield eight ounces of white crystals. But the product depends very much on the quality of the juice, which is very variable as to the quantity of citric acid which it contains. The more recent the juice the better the quality. That which is stale will sometimes be quite sour, without containing any citric acid, in consequence of having undergone the acetous fermentation.

In decomposing the citrate of lime by sulphuric acid, it is not prudent to trust altogether to the appearance of the liquor, in deciding when the decomposition is complete. A more certain criterion is to filter a small portion of the liquor, and test it with acetate of lead. If no sulphuric acid be present in excess, the precipitate will consist of citrate of lead, and be entirely soluble in nitric acid. On the contrary supposition, the precipitate will be a mixture of citrate and sulphate of lead, the latter of which will remain undissolved on the addition of nitric acid.

It is desirable to have a slight excess of sulphuric acid; as it rather favours than otherwise the crystallization of the citric acid. It is found necessary also, to add occasionally a small portion of sulphuric acid to the citric acid liquor, during the progress of its concentration.

Citric acid is manufactured in different cities of the United States, for use in the arts and in medicine. In Philadelphia it is made in the usual manner, from the juice of limes and lemons, to the extent, perhaps, of 500 pounds annually, and commands the wholesale price of $2 75, or $3 00 per pound. The juice which is imported is of variable quality, furnishing from four to six ounces of the pure crystallized acid to the gallon.

Citric acid is very properly placed in the materia medica of the United States and Edinburgh Pharmacopœias, as an article purchased from the manufacturing chemist, and not made by the apothecary. The Dublin College introduces it among its preparations; while the London places it in the materia medica, and also gives a process for preparing it.

The following is an outline of the processes of the London and Dublin Pharmacopœias for preparing this acid. The London College adds an ounce of prepared chalk, or a sufficient quantity for saturation, to a pint of lemon juice. The resulting citrate of lime is then dried, and decomposed by means of nine fluidounces of diluted sulphuric acid. The process of the Dublin College is the same, with the exception that the dried citrate is decomposed by a quantity of diluted sulphuric acid, equal to eight times the weight of the chalk employed.

It would seem, that both these Colleges use an excess of sulphuric acid. The acid should always bear a fixed relation to the chalk employed; and this relation was ascertained by Mr. Phillips to be nearly six fluidounces of the officinal diluted sulphuric acid to the ounce of chalk. This chemist considers the drying of the citrate to be an injudicious direction, as the salt will be more readily decomposed in the moist state.

Properties. Citric acid is a white crystallized solid, often in large crystals, permanent in the air, and having the form of rhomboidal prisms with dihedral summits. Its sp. gr. is 1.6. Its taste is strongly acid, and almost caustic. When heated, it dissolves in its water of crystallization, and at a higher temperature undergoes decomposition, becoming yellow or brown, and forming a very sour syrupy liquid, which is uncrystallizable. By destructive distillation, it gives rise to water, empyreumatic oil, acetic and carbonic acids, carburetted hydrogen, and a peculiar acid, called pyrocitric.

Citric acid dissolves in three-fourths of its weight of cold, and half its weight of boiling water. A weak solution of it has an agreeable taste, but cannot be kept, as it undergoes spontaneous decomposition. It is incompatible with alkaline solutions, whether pure or carbonated; converting them into citrates; also with the earthy and probably all the metallic carbonates, most acetates, the alkaline sulphurets, and soaps. It is characterized by its taste, by the shape of its crystals, and by its forming an insoluble salt with lime, and a deliquescent one with potassa. Sometimes the larger crystals of tartaric acid are sold for the citric, a fraud which is readily detected by the addition of carbonate of potassa, which forms with the substituted acid a crystalline precipitate of bitartrate of potassa, (cream of tartar.) Druggists throughout the United States may obtain citric acid in Philadelphia, in full confidence of its purity, from the warehouse of Mr. John Elliott, manufacturing chemist, who prepares it on a large scale, and of the best quality.

Composition. This acid consists of two equivalents of hydrogen 2, four equivalents of carbon 24.48, and four equivalents of oxygen 32=58.48. The crystallized acid contains two equivalents of water 18, making its equivalent 76.48.

Medical Properties. Citric acid is principally employed for making a substitute for lemonade, and in the composition of the neutral mixture and effervescing draughts. When added in the quantity of nine drachms and a half to a pint of distilled water, it forms a solution of the average strength of lime juice. Of this solution, or of lemon juice, a scruple of bicarbonate of potassa saturates three fluidrachms and a half; a scruple of carbonate of potassa, four fluidrachms; and a scruple of carbonate of ammonia, six fluidrachms. Half a fluidounce of lemon juice, or of an equivalent solution of citric acid, when saturated, is considered as a dose. An agreeable substitute for lemonade may be formed by dissolving from two to four parts of the acid, mixed with a little sugar and oil of lemons, in nine hundred parts of water; or a scruple of the acid may be dissolved in a pint of water, and sweetened to the taste with sugar which has been rubbed on fresh lemon-peel. ACIDUM MURIATICUM. *U.S., Lond., Ed., Dub.*

Muriatic Acid.

Spirit of sea-salt, Marine acid, Hydrochloric acid; Acide hydro-chlorique liquide, *Fr.;* Salzsäure, Kochsalzsäure, *Germ.;* Acido muriatico, *Ital., Span.*

The muriatic acid of pharmacy and the arts, is a solution of muriatic acid *gas* in water, and is sometimes called *liquid* muriatic acid. Its officinal sp. gr., according to the United States, London, and Dublin Pharmacopœias, is 1.16; according to the Edinburgh, 1.17. The three British Colleges give a process for its preparation; while in the United States Pharmacopœia, it is placed exclusively in the list of materia medica, as an article to be procured from the manufacturing chemist.

Preparation. Muriatic acid is obtained by the action of sulphuric acid on chloride of sodium or common salt. It is procured, on a large scale, by distilling the salt with an equal weight of sulphuric acid, somewhat diluted with water, from iron stills furnished with earthen heads, into earthenware receivers containing water. Thus obtained, it is contaminated with iron and other impurities, and is not fit for medicinal purposes.

The acid is generally prepared in the laboratory, by saturating distilled water with the gas in a Woulfe's apparatus. A quantity of pure fused* common salt is introduced into a retort or matrass, placed in a sand-bath. The vessel is then furnished with an S tube, and connected with the series of bottles, each two-thirds full of water. A quantity of sulphuric acid is then gradually added, equal in weight to the common salt employed, and diluted with one-third of its weight of water. The materials ought not to occupy more than half the body of the retort. When the extrication of the gas slackens, heat is to be applied, and gradually increased until the water in the bottles refuses to absorb any more, or until upon raising the heat, no more gas is found to come over. As soon as the process is completed, boiling water is to be added to the contents of the retort, in order to facilitate the removal of the residue. During the progress of the saturation, the water in the several bottles suffers an increase of temperature, which lessens its power of absorption. It is therefore expedient, in order to obtain a strong acid, to keep the bottles cool by means of water or ice. The connecting tubes need not plunge deeply into the acid.

The rationale of the process for obtaining this acid is sufficiently simple. Common salt is a compound of chlorine and sodium; muriatic acid, of chlorine and hydrogen; and liquid sulphuric acid, of dry sulphuric acid and water. The water is decomposed; its oxygen, combining with the sodium of the common salt, generates soda, which unites with the sulphuric acid to form sulphate of soda; while the hydrogen and chlorine, being in the nascent state, combine, and escape as muriatic acid gas. The residue of the process is consequently sulphate of soda or Glauber's salt. It is reserved by the British Colleges to be dissolved and crystallized, in order to form the officinal sulphate of soda. (See *Sodæ Sulphas.*)

The following is a synopsis of the proportions of the ingredients prescribed by the British Colleges for obtaining this acid:—*London*, two pounds of dried chloride of sodium, twenty ounces of sulphuric acid, and a pint and a half of distilled water:—*Edinburgh*, equal weights of salt, acid, and water; the salt having been previously exposed to a red heat:—*Dublin*, one hundred parts of dried salt, eighty-seven of commercial sulphuric acid, and one hundred and twenty-four of water.

The three Colleges distil the materials to dryness, the London and Edinburgh directing the use of a sand-bath. One-third of the water prescribed in the London and Edinburgh Pharmacopœias, and one-half of that directed in the Dublin, is mixed with the sulphuric acid; the rest being put into the receiver to absorb the gas. The diluted acid is allowed to cool before being added to the salt. The London College add the salt to the diluted acid, previously introduced into the retort, while the other two Colleges pursue the more convenient plan of adding the acid to the salt.

From the above view, it is perceived that the British Colleges differ as to the proportion of acid to the salt. Theory calls for a little less than 82 parts of the liquid acid to 100 of the common salt; while the London College uses about 83 parts, the Dublin 87, and the Edinburgh 100 parts of acid to that quantity of salt. The London proportions are, therefore, nearest the theoretical quantities, and would even seem to furnish a slight excess of acid; but from careful experiments made by Dr. Barker of Dublin, it appears to be demonstrated, that to decompose completely the whole of the salt, 87 parts of strong acid are necessary; for it is a principle now generally conceded, as was contended for many years ago by Dr. Hope, that to produce complete decomposition of a salt, it is sometimes necessary to use more than an equivalent quantity of the decomposing agent. Accordingly, Dr. Hope declares in favour of the Edinburgh process, that equal weights of acid and salt give a larger product of muriatic acid, with less expense of time and fuel, than when a smaller quantity of acid is employed.

---

* According to Thenard, the fusion of the common salt will very much facilitate the conducting of the process.

The drying and igniting of the common salt is not done with a view, as was formerly supposed, of driving off water of crystallization, as it does not contain any; but it has been asserted by Dr. Duncan, that the ignition has the effect of affording a less coloured product, while it secures the incidental advantage of freeing the salt from the nitrate of potassa.

Properties of the Liquid Acid. Muriatic acid, when pure, is a transparent, colourless liquid, of a corrosive taste and suffocating odour. Exposed to the air, it emits white fumes, owing to the escape of the acid gas, and its union with the moisture of the atmosphere. As ordinarily seen, it has a straw colour, due to the presence either of iron or of a minute portion of organic matter, such as cork, wood, &c. When concentrated, it blackens organic substances like sulphuric acid. Its sp. gr. varies with its strength. When as highly concentrated as possible, its density is 1.21; when of proper medicinal strength, 1.16. Mixed with nitric acid, it forms nitro-muriatic acid, or aqua regia. (See *Acidum Nitromuriaticum.* Dub.)

As it is desirable to know, on many occasions, in chemical and pharmaceutical operations, the quantity of strong liquid acid, of acid gas, and of chlorine, contained in samples of acid of different densities, we subjoin a table by Dr. Ure, containing this information, as abridged by Dr. Duncan.

Table of the Quantity of Liquid Muriatic Acid of sp. gr. 1.2, *of Muriatic Acid Gas, and of Chlorine, in* 100 *parts of Liquid Acid of different densities.*

Muriatic acid is characterized by forming, on the addition of nitrate of silver, a white precipitate, (chloride of silver,) which is insoluble in acids, but readily soluble in ammonia. It is incompatible with alkalies and most earths, with oxides and their carbonates, and with sulphuret and tartrate of potassa, tartar emetic, tartarized iron, nitrate of silver, and solution of subacetate of lead.

Adulterations. This acid, when pure, will evaporate without residue in a platinum spoon. If sulphuric acid be present, muriate of baryta will cause a precipitate, in the dilute acid, of sulphate of baryta. If nitric acid be present, the muriatic acid will have the properties of *aqua regia*, and will consequently dissolve gold-leaf. Iron may be detected by saturating the dilute acid with carbonate of soda, and then adding ferrocyanate of potassa, which will strike a blue colour in case that metal is present.

Properties of Muriatic Acid Gas. Muriatic acid gas is a colourless elastic fluid, possessing a pungent odour, and irritating properties to the organs of respiration. It destroys life and extinguishes flame. It reddens litmus strongly, and has the other properties of a strong acid. Its sp. gr. is 1.269. Subjected to a pressure of 40 atmospheres, at the temperature of 50°, it is condensed into a transparent liquid. It absorbs water with the greatest avidity, and according to the temperature and pressure, unites with a greater or less quantity of that liquid. Water, at the temperature of 69°, takes up 464 times its volume of the gas, increasing one-third in bulk, and about three-fourths in weight. Water thus saturated constitutes the strong liquid acid already described. With metallic oxides it forms either a muriate of the oxide, or a chloride of the metal and water.

Composition. Muriatic acid gas consists of one equiv. of chlorine 35.42, and one equiv. of hydrogen $1=36.42$; or of one volume of chlorine and one of hydrogen united without condensation. It is called *hydrochloric* and *chlorohydric* acid by the French chemical writers.

Medical Properties. Muriatic acid is refrigerant and antiseptic. It is exhibited, largely diluted with water, in fevers, some forms of syphilis, and in the phosphatic calculous diathesis. Dr. Paris has given it with success in the most malignant cases of typhus and scarlatina, administered in a strong infusion of quassia. The same writer has found it one of the most efficacious remedies for preventing the generation of worms, after a free evacuation of the bowels. It proves also a good adjunct to gargles in ulcerated sore throat and scarlatina maligna. The dose for internal exhibition is from ten to twenty minims in a sufficient quantity of some bland fluid, as barley water or gruel. In the composition of gargles it may enter in the proportion of from half a fluidrachm to two fluidrachms to six fluidounces of the vehicle.

Toxicological Properties. Muriatic acid, when swallowed in a poisonous dose, produces blackness of the lips, fiery redness of the tongue, hickups, violent efforts to vomit, and agonizing pain in the stomach. There is much thirst, great restlessness, a dry and burning skin, and a small concentrated pulse. If the acid has been recently swallowed, white vapours of a pungent smell are emitted from the mouth. The best antidote is magnesia, which acts by saturating the acid. Soap is also useful for the same reason. In the course of the treatment, bland and mucilaginous drinks must be freely given. When inflammation supervenes, it must be treated on the general principles for combating inflammation from other causes.

This is a very powerful acid, obtained from nitrate of potassa or nitre, by the action of sulphuric acid. It is officinal in all the Pharmacopœias. The British Colleges give a process for obtaining it; but, in the United States Pharmacopœia, it is more properly placed in the materia medica list, as an article to be purchased from the manufacturing chemist. Its officinal sp. gr. in the United States and Lond. Pharm., is 1.5; in the Dublin, 1.49. The Edin. College does not indicate its sp. gr.

The usual process adopted in the laboratory for obtaining this acid is to add to nitrate of potassa in coarse powder, contained in a retort, an equal weight of strong sulphuric acid, poured in by means of a tube or funnel, so as not to soil the neck. The materials should not occupy more than two-thirds of the capacity of the retort. A receiver being adapted, heat is applied by means of a spirit-lamp, the naked fire, or a sand-bath, moderately at first, but afterwards more strongly when the materials are observed to be beginning to get solid, in order to bring the whole into a state of perfect fusion. Red vapours will at first arise, and afterwards disappear in the progress of the distillation. Towards its close they will be reproduced, which is an indication that the process is completed.

The rationale of this process is as follows. Nitrate of potassa is a dry salt, consisting of one equiv. of nitric acid and one of potassa. Liquid sulphuric acid consists of one equiv. of dry sulphuric acid and one equiv. of water; and liquid nitric acid, of one equiv. of dry nitric acid and one and a half equiv. of water. The equivalent quantities of the materials are one equiv. of nitrate of potassa and two equiv. of liquid sulphuric acid. Two equiv. of dry sulphuric acid, combine with the one equiv. of potassa, forming one equiv. of bisulphate of potassa, which remains in the retort retaining half an equiv. of water; while the remaining one and a half equiv. of water from the sulphuric acid, uniting with one equiv. of dry nitric acid, form one equiv. of liquid nitric acid, which distils over. Thus it is perceived that liquid sulphuric and nitric acids differ in this respect, that the former contains one, the latter one and a half equivalents of water, to one of the dry acid. Now nitric acid is incapable, according to Mr. Phillips, (*Phil. Mag.* ii. 430,) of existing in the ordinary liquid state, without being combined with at least one and a half equivalents of water; and as the residual bisulphate requires half an equivalent more, it becomes necessary, in effecting the decomposition of the nitre, to employ a quantity of liquid sulphuric acid which contains two equivalents of water.

The quantities of salt and acid for mutual decomposition, are in round numbers 102 of the former and 98 of the latter. Now this approaches very nearly to equal weights, the quantities found most eligible in practice; and when it is recollected that the theoretical proportions are based upon the supposition of a perfectly concentrated sulphuric acid, which is not always the condition of the acid of commerce, the slight excess of acid, which equal weights would seem to give, may be necessary to make up for any deficiency in its strength.

The British Colleges differ somewhat in the proportion of the materials which they employ for making this acid. The following is an outline of their respective processes.

The *London* College takes equal weights, (two pounds, each,) of dried nitrate of potassa and sulphuric acid. These are mixed in a glass retort, and the nitric acid is distilled by means of a sand-bath, until red vapours arise. The acid is then redistilled from an ounce of nitrate of potassa. Two hundred and twelve grains of crystallized carbonate of soda are saturated by one hundred grains of this acid.

The *Dublin* College mixes one hundred parts of nitrate of potassa with ninety-seven parts of commercial sulphuric acid, "in a glass retort, and with an apparatus adapted to collecting the acid products, distils until the residuum in the retort concretes, and again becomes liquid."

The *Edinburgh* College first obtains a red fuming acid under the name of nitrous acid, by one formula; and by a separate one, exposes this to a gentle heat to dissipate the red portion, and convert it into nitric acid. The following is an outline of these two processes.

Acidum Nitrosum. *Ed.*—Pour sixteen ounces of sulphuric acid on two pounds of bruised nitrate of potassa, and distil by means of a sand-bath by a heat gradually increased, until the iron pot begins to be red-hot. The sp. gr. of this acid is 1.52.

Acidum Nitricum. *Ed.*—Take any quantity of nitrous acid, and pour it into a glass retort. Then having adapted a cooled receiver, expose the acid to a very gentle heat, until the red portion has passed over, and the nitrous acid, nearly deprived of colour, has been converted into nitric acid.

The proportions of the London College are perhaps the best for obtaining nitric acid, for reasons already explained. They are preferred also by Thenard, and, being equal weights, have the advantage of being easily remembered. The redistillation from nitre, ordered by this College, is intended to free the product from any contaminating sulphuric acid. It is, however, unnecessary; for if the sulphuric acid be added in the process, without soiling the neck of the retort, the nitric acid obtained will never be impure from this cause.

The Dublin proportions of acid and nitre were deduced by Dr. Barker from careful experiments, and approach more nearly to the exact quantities for mutual decomposition than equal weights. They may be considered as virtually the same with the London.

The Edinburgh College uses a proportion of sulphuric acid considerably less than the other Colleges, being only two-thirds of the weight of the nitre. The consequence is, that sufficient water is not present to condense the elements of the nitric acid; and accordingly a part of the acid is resolved into nitric oxide or red nitrous acid fumes, which, uniting with the undecomposed acid, give rise to a red acid product, erroneously called by the College *nitrous* acid. Hence arises the necessity of the subsequent application of heat to dissipate the red portion, in the process for bringing it to the state of nitric acid.

According to the Edinburgh proportions, it is perceived that there is more than one, but less than two equivalents of sulphuric acid to one of the salt. It has been very justly remarked by Mr. Phillips, that one equivalent of sulphuric acid is competent to decompose one equivalent of nitrate of potassa, but not sufficient, from the deficiency of water, to condense and preserve all the nitric acid extricated. Dr. Hope, however, Professor of Chemistry in the University of Edinburgh, defends the process of the College, and insists that the proportion of sulphuric acid used is sufficient to decompose the nitre, with the result of giving an acid of great strength and free from sulphuric acid. The late Dr. Duncan also advocated the Edinburgh proportions, by alleging that they are the same as those of the Paris Codex.

The question of the relative eligibility of the London and Edinburgh processes is not to be decided solely by the strength of the product, but by its strength and amount considered conjointly, and by those incidental advantages or disadvantages which may attach to either process. Neither ought the nitrous acid product to be made the basis of comparison; but rather the nitric acid, which may be obtained from it by the subsequent exposure to heat. Comparing the two processes in this point of view, it cannot fail to strike every one that the copious production of red vapours, as happens in the Edinburgh process, must lessen the amount of the nitric acid; and though it may be alleged, that they are in the nitrous acid, they are lost when this is converted into nitric acid. Mr. Phillips found that 150 parts of red nitrous acid, of the sp. gr. 1.52, yielded, by the application of heat, only 114 of pale nitric acid, of sp. gr. 1.49; while 27 parts of red nitrous acid of sp. gr. 1.58 distilled over. The loss, therefore, amounted to 9 parts. It is also an incidental disadvantage of the Edinburgh process, that the residual salt is a mixture of sulphate and bisulphate of potassa, which is not so readily washed out as the bisulphate, and the removal of which is much more apt to cause the fracture of the retort. Any saving which arises from the use of less sulphuric acid in the Edinburgh process, is perhaps more than counterbalanced by this circumstance.

As the main objection to the process of the Edinburgh College is that the quantity of water supplied to the elements of the nitric acid is too small, while the sulphuric acid used is amply sufficient to decompose the salt; the question arises, how far it would answer a good purpose to add the necessary quantity of water to the sulphuric acid, before its addition to the nitre. This plan has been adopted by Döbereiner, who has found that a larger though less concentrated product is obtained when one part of water is added to nine parts of sulphuric acid, just before its addition to the nitre.

As in medicine and most of the arts, a strong nitric acid is not required, we would suggest, that one equivalent of nitre might be decomposed with least loss of acid, by being distilled with one equivalent of liquid sulphuric acid, previously united with three and a half equivalents of water. The water in this case would form a nitric acid with four equivalents of water, constituting a liquid acid, in which the acid and water are united with the strongest affinity, and which boils without undergoing any change. On these principles, Berzelius states, that where it is not necessary to have a concentrated nitric acid, it is best to dilute the sulphuric acid with an equal weight of water, before commencing the distillation. Whenever this plan is adopted, iron distillatory vessels cannot be used, as the dilute sulphuric acid would act on them much more rapidly than when it is in a concentrated state.

We have stated above, that the red acid of the Edinburgh College is erroneously called nitrous acid. It is in fact nitric acid holding nitric oxide in solution. Indeed, the acid of the other Colleges, is to a certain extent of the same nature, as it is generally yellow from the presence of a small quantity of the same gas. Real nitric acid is perfectly colourless. Nevertheless, it may be proper to add, that, according to the equivalent numbers, if we suppose two equivalents of nitric acid, united to one equivalent of nitric oxide, the compound would correspond to three equivalents of nitrous acid. The red acid, whatever may be its exact nature, is known to be considerably denser than the real pale nitric acid. The officinal red acid, as already stated, has the density of 1.52. When at its highest degree of concentration, it weighs, according to Meissner, 1.63; while the strongest perfectly colourless nitric acid, according to the same authority, has the sp. gr. of 1.48 only.

Upon the whole, we prefer the process of the Dublin College for obtaining nitric acid. The proportions adopted are good, and the unnecessary redistillation of the London College is omitted.

Preparation of Nitric Acid for the Arts. Two strengths of this acid occur in the arts;—*double aqua fortis*, which is half the strengh of concentrated nitric acid, and *single aqua fortis*, which is half as strong as the double. Aqua fortis is frequently obtained by distilling a mixture of nitre and calcined sulphate of iron. By an interchange of ingredients, sulphate of potassa and nitrate of iron are formed, the latter of which, at the distilling heat, readily yields its nitric acid. The sulphate of potassa is washed out of the residue, and the peroxide of iron which is left, is sold, under the name of colcothar, to the polishers of metals. The distillation is performed in large cast-iron retorts, lined on the inside with a thick layer of red oxide of iron, to protect them from the action of the acid. The acid is received in large glass vessels containing water. A considerable portion of the acid is decomposed by the heat into reddish vapours, which subsequently dissolve in water, and absorb the oxygen which has been disengaged. The acid thus obtained is red and tolerably strong; but it is diluted with water before being thrown into commerce. The sp. gr. of this acid is about 1.22.

In France, nitric acid is manufactured on the large scale from nitre and sulphuric acid, in cast-iron cylinders. The cylinders are disposed horizontally across a furnace, and are strewed internally throughout their whole length with nitre. Two circular cast-iron plates, each pierced with a hole, serve to close the extremities. At one, the sulphuric acid is poured in, and by means of a stoneware tube connected with the other, the nitric acid is collected in receivers. The sulphate of potassa is removed after each operation. The iron cylinders are acted upon by the acid; yet, notwithstanding this disadvantage, the process, when conducted in such vessels, is attended with a great saving of expense.

In England, nitric acid is generally procured for the purposes of the arts, by distilling the materials in earthenware retorts, or cast-iron pots with an earthen head, connected with a series of glass or stoneware receivers containing water. The proportion of sulphuric acid employed by the manufacturer, is between one and two equivalents; and hence the product has an orange-red colour, which is removed by heating the acid.

In the United States, nitric acid is made on the large scale, in a distillatory apparatus, having the same general arrangement as in France and England. Sometimes a cast-iron cylinder is used as in France, and sometimes a thick cast-iron pot, with an earthenware head. The pot is set in brickwork over a fire-place, and the materials having been placed in it, the head is luted on with a fat lute, and made to communicate with two receivers, either of stoneware or glass, connected together by means of a tube. Large demijohns of glass answer the purpose of receivers very well. The incondensible products are made to pass by means of a tube into a portion of water. The quantity of sulphuric acid employed in different establishments, varies from one-half to two-thirds of the weight of the nitre. In a very large chemical establishment in this city, which we have had the pleasure of inspecting, through the kindness of the liberal proprietor, the proportions employed for a charge are 150 pounds of nitre to 84 pounds of strong sulphuric acid. Nitrate of soda, having been latterly imported into the United

States in large quantities from Peru, has been used by some manufacturing chemists to obtain nitric acid. It yields a larger amount of acid for a given weight than the nitrate of potassa; but the residuum, sulphate of soda, is less valuable than sulphate of potassa. The latter salt may be sold to the alum makers at the average price of twenty dollars per ton.

Nitric acid is never imported into the United States; the foreign article not being able to enter into competition with the home manufacture.

Properties. Nitric acid, so called from nitre, is a dense liquid, extremely sour and corrosive. It was discovered by Raymond Lully, in the 13th century, and its constituents, by Cavendish, in 1784. When perfectly pure, it is colourless; but as usually obtained, it has a straw-colour, owing to the presence of nitrous acid. Exposed to the air, it emits white fumes, possessing a disagreeable odour. By the action of light, it undergoes a slight decomposition and becomes yellow. Its sp. gr., when as highly concentrated as possible, is 1.513. It acts powerfully on animal matter, producing its decomposition. On the living fibre it operates as a strong caustic. It stains the skin and most animal substances of an indelible yellow colour. On vegetable matter, it acts, when concentrated, by imparting oxygen, converting the carbon into carbonic acid, and the hydrogen into water. When diluted, it converts most animal and vegetable substances into oxalic, malic, and carbonic acids. The general character of its action is to impart oxygen to other bodies, which it is enabled to do in consequence of the large quantity of this principle which it contains in a state of loose combination. It acidifies sulphur and phosphorus, and oxidizes all the metals, except chromium, tungsten, columbium, cerium, titanium, osmium, rhodium, gold, platinum, and iridium. In the liquid state, it always contains water, which is essential to its existence in that state. Mixed with a certain quantity of water, it forms the diluted nitric acid of the London and Dublin Pharmacopœias. (See *Acidum Nitricum Dilutum.*) It combines with salifiable bases and forms nitrates. With muriatic acid, it constitutes nitro-muriatic acid or aqua regia. (See *Acidum Nitromuriaticum*, Dub.) When of the sp. gr. 1.42, its composition being one equivalent of dry acid and four equivalents of water, it boils at 250°. When either stronger or weaker, it volatilizes at a lower temperature; and by losing more acid than water in the first case, and more water than acid in the second, it constantly approaches to the sp. gr. of 1.42, when its boiling point becomes stationary.

As in many chemical and pharmaceutical operations, a nitric acid below the standard strength is necessarily employed, it often becomes important to know the proportion of dry acid, and of acid of the standard strength of 1.5, contained in an acid of any given specific gravity. The following table, drawn up from experiments by Dr. Ure, gives information on these points.

Table, showing the Quantity of Liquid Nitric Acid, (sp. gr. 1.5.) *and of Dry Nitric Acid, contained in* 100 *parts of the Acid at different Densities.*

The *nitrous acid* of the Edinburgh College (*Acidum Nitrosum*) is a red or orange-coloured liquid, exceedingly volatile, and emitting red fumes of a suffocating odour. It consists of nitric acid holding nitric oxide in solution. When diluted with water, it parts with the nitric oxide and becomes successively blue, green, and yellow. Mixed with an equal weight of water, it forms the dilute nitrous acid of the Edinburgh College. (See *Acidum Nitrosum Dilutum.*)

Nitric acid, when uncombined, is recognized by its peculiar action on silver and copper, and by its forming nitre when saturated with potassa. When in the form of a nitrate, it is detected by its action on gold-leaf, after the addition of muriatic acid, in consequence of the evolution of the chlorine; or it may be discovered, according to Dr. O'Shaughnessy, by heating the supposed nitrate in a test tube with a drop of sulphuric acid, and then adding a crystal of morphia. If nitric acid be present, it will be set free by the sulphuric acid, and communicate an orange-red followed by a yellow colour to the morphia. To prevent all ambiguity, arising from the accidental presence of nitric acid in the sulphuric acid employed, the operator should satisfy himself by a separate experiment, that the latter acid has no power to produce the colours mentioned with morphia. (*Turner's Chemistry, Fifth Lond. Edit.*)

The most common impurities in nitric acid are sulphuric and muriatic acids; the former derived from the acid used in the process, the latter from common salt, which is not an unfrequent impurity in nitre. They may be detected by adding a few drops of the solution of muriate of baryta and nitrate of silver to separate portions of the nitric acid, diluted with three or four parts of distilled water. If these precipitants should produce a cloud, the muriate will indicate sulphuric acid, and the nitrate, muriatic acid. These impurities may be separated by adding nitrate of silver in slight excess, which will precipitate them as chloride and sulphate of silver, and then distilling nearly to dryness in very clean vessels. The sulphuric acid may also be got rid of by distilling from a fresh portion of nitre, as practised by the London College. These impurities, however, do not in the least affect the medicinal properties of the acid.

Composition. The officinal nitric acid consists of one equiv. of dry acid 54.15, and one and a half equiv. of water 13.5=67.65. The dry acid consists of one equiv. of nitrogen 14.15, and five equiv. of oxygen 40=54.15; or in volumes of one volume of nitrogen, and two and a half volumes of oxygen, supposed to be condensed, to form nitric acid vapour, into one volume. The strongest possible liquid acid consists of one equiv. of dry acid and one equiv. of water, and has the sp. gr. 1.513. (*Thenard.*)

Incompatibles. Most of the substances with which nitric acid is incompatible, may be inferred from what has been already said. It is incompatible with protosulphate of iron, which it converts into persulphate, with salifiable bases, carbonates, and sulphurets, and with the acetates of lead and potassa. It is also capable of decomposing alcohol, with which it forms nitric ether.

Medical Properties. Nitric acid is tonic and antiseptic. Largely diluted with water, it forms a good acid drink in febrile diseases, especially typhus. Dr. Duncan frequently gave it, with unequivocal advantage, in the low typhus occurring in the suburbs of Edinburgh. In syphilis, and in the chronic hepatitis of India, it is highly extolled by Dr. Scott, formerly of Bombay. It cannot be depended upon as a remedy in syphilis, but is often an excellent adjuvant in worn out constitutions, either to prepare the system for the use of mercury, or to lessen the effects of that metal on the constitution, by supporting the tone of the system. Externally, it has been used with advantage as a lotion to fetid ulcers, of the strength of about twelve minims to the pint of water. As nitric acid dissolves both uric acid and the phosphates, it was supposed to be applicable to those cases of gravel in which the uric acid and the phosphates are mixed; but subsequent experience has not confirmed its practical efficacy in such cases. Nevertheless, when the sabulous deposite depends upon certain states of disordered digestion, this acid may prove serviceable by restoring the tone of the stomach The dose is from five to twenty minims in three fluidounces or more o. water, given three or four times a day.

Nitric acid, in a state of vapour, is considered useful for destroying contagion; and hence is employed in purifying gaols, hospitals, and ships, and other infected places. It is prepared for use by the extemporaneous decomposition of nitre by sulphuric acid. Half an ounce of powdered nitre is put into a saucer, which is placed in an earthen dish containing heated sand. On the nitre, two drachms of sulphuric acid are then poured, and the nitric acid fumes are immediately disengaged. The quantities just indicated are considered to be sufficient for disinfecting a cubic space of ten feet. Fumigation in this manner was first introduced by an English physician, Dr. Carmichael Smyth, who received from the British Parliament for its discovery, a reward of five thousand pounds. It may well be doubted whether the nitric acid, as a disinfector, is at all comparable to chlorine; and since the introduction of the chlorides of lime and soda as disinfecting agents, this gas has been brought into so manageable a form, that its use may very well supercede that of every other agent employed with similar intentions. (See *Chloride of Lime* and *Chloride of Soda*, in the Appendix.)

Properties as a Poison. Nitric acid, in its concentrated state, is the mineral poison most frequently taken for the purpose of self-destruction. Immediately on swallowing it, there are produced burning heat in the mouth, œsophagus, and stomach; acute pain; disengagement of gas; abundant eructations; nausea and hiccup. Soon after, there occur repeated and excessive vomiting, the vomited matter having a peculiar odour and taste; tumefaction of the abdomen, with exquisite tenderness; a feeling of coldness on the surface; horripilations; icy coldness of the extremities; small depressed pulse; horrible anxieties; continual tossings and contortions; extreme thirst. The breath becomes extremely fetid, and the countenance exhibits a complete picture of suffering. The cases are almost uniformly fatal. The best remedies are repeated doses of magnesia as an antidote, mucilaginous drinks in large quantities, olive or almond oil in very large doses, emollient fomentations, and clysters. Until magnesia can be obtained, an immediate resort to a solution of soap in large amount will be proper.

ACIDUM SULPHURICUM. *U.S.*, *Lond.*, *Ed.*

Sulphuric Acid.

Off. Syn. ACIDUM SULPHURICUM VENALE, *Dub.*

Oil of vitriol; Acide sulphurique, *Fr.;* Vitriolöl, Schwefelsäure, *Germ.;* Acido solforico, *Ital.;* Acido sulfurico, *Span.*

Sulphuric acid is placed in the Materia Medica of all the Pharmacopœias noticed in this work, as an article to be obtained from the wholesale manufacturer. Its officinal sp. gr., as prescribed in the U.S. Pharm., is 1.8485; in the London and Dublin, 1.850; and in the Edinburgh, 1.845. These differences in density are so slight, that a virtual agreement may be assumed to exist in the strength of the different officinal acids.

Preparation. Sulphuric acid is obtained by burning sulphur, mixed with one-eighth of its weight of nitre, over a stratum of water, contained in a chamber lined with sheet lead. If the sulphur were burnt by itself, the product would be sulphurous acid, which contains only two-thirds as much oxygen as sulphuric acid. The object of the nitre is to furnish, by its decompositon, the requisite additional quantity of oxygen. To understand the process, it is necessary to bear in mind that nitric acid contains five, sulphuric acid three, sulphurous acid two, nitric oxide two, hyponitrous acid three, and nitrous acid four equivalents of oxygen, combined with one equiv. of their several radicals. One equiv. of sulphur decomposes one equiv. of nitric acid of the nitre, and becomes one equiv. of sulphuric acid, which combines with the potassa of the nitre to form sulphate of potassa. In the mean time, the nitric acid, by furnishing three equiv. of oxygen to form the sulphuric acid, is converted into one equiv. of nitric oxide, which is evolved. This gas, by combining with two equiv. of the oxygen of the air, immediately becomes nitrous acid vapour, which diffuses itself throughout the leaden chamber. While these changes are taking place, the remainder of the sulphur is undergoing combustion, and filling the chamber with sulphurous acid gas. The nitrous and sulphurous acid gases, being thus intermingled in the chamber, react on each other: one equiv. of nitrous acid, by the aid of moisture, unites with one equivalent of sulphurous acid, so as to form a crystalline compound consisting of one equiv. of sulphuric acid, and one equiv. of hyponitrous acid, united to a portion of water. This compound falls into the water of the chamber, and instantly undergoes decomposition. The sulphuric acid dissolves in the water, and the hyponitrous acid, resolved, at the moment of its extrication, into nitrous acid and nitric oxide, escapes with effervescence. The nitrous acid thus set free, as well as that reproduced by the nitric oxide uniting with the oxygen of the atmosphere, again reacts with the sulphurous acid and humidity, and gives rise to a second portion of the crystalline compound, which undergoes the same changes as the first. In this manner the nitric oxide performs the part of a carrier of oxygen from the air of the chamber to the sulphurous acid, to convert the latter into sulphuric acid. The residue of the process consists of sulphate of potassa and is sold to the alum makers.

Preparation on the Large Scale. The leaden chambers vary in size, but are generally from thirty to thirty-two feet square, and from sixteen to twenty feet high. The floor is slightly inclined to facilitate the drawing off of the acid, and covered to the depth of several inches with water. There are several modes of burning the mixture of sulphur and nitre, and otherwise conducting the process, but that pursued in France is as follows. Near to one of the sides of the chamber, and at about a foot from its bottom, a cast iron tray is placed over a furnace, resting on the ground, with a chimney having no communication with the chamber, and its mouth opening externally. On this tray the mixture is placed, being introduced by a square opening, which may be shut by means of a sliding door, and the lower side of which is level with the surface of the tray. The door being shut, the fire is gradually raised in the furnace, whereby the sulphur is inflamed, and the products already spoken of are generated. When the combustion is over, the door is raised, and the sulphate of potassa removed. A fresh portion of the mixture is then placed on the tray, and the air of the chamber is renewed by opening a door and valve situated at its opposite side. Next, the several openings are closed, and the fire is renewed. These operations are repeated with fresh portions of the mixture, every three or four hours, until the water at the bottom of the chamber has reached the sp. gr. of about 1.2. It is then drawn off and transferred to leaden boilers, where it is boiled down until it has nearly attained the sp. gr. of 1.5. Its further concentration requires a higher heat than lead can bear, and accordingly, it is transferred to large glass or platinum retorts, where it is evaporated as long as water distils over. This water is slightly acid, and is thrown back into the chamber. When the acid is fully concentrated, opaque grayish-white vapours arise, and the process, by their appearance, is known to be finished. The acid is allowed to cool, and transferred to large demijohns of green glass, called carboys, which, for greater security, are surrounded with straw or wicker-work, and packed in tubs, or flour barrels sawed in two.

The English method of manufacturing this acid, as described by Mr. Parkes, is somewhat different. The mixture is usually spread on iron or leaden plates, resting on stands of lead within the chamber, placed at some distance from each other, and a foot or two above the surface of the water. The sulphur is then lighted by means of a hot iron, and the doors closed. If the sulphur and nitre be well mixed, the combustion will last for thirty or forty minutes; and in three hours from the time of lighting, the condensation of the gases having in that interval been completed, the doors are thrown open for fifteen or thirty minutes, to admit fresh atmospheric air, and to allow time for the residuary nitrogen to escape, preparatory to the next burning. These operations are repeated with fresh charges of the mixture, every four hours, both night and day, until the water has attained the requisite acid impregnation, when it is transferred to leaden boilers, and otherwise treated as already explained. The quantity of the charge for each burning is determined by the size of the chamber, allowing one pound of the mixture for every three hundred cubic feet of atmospheric air which it may contain.

As, in the manufacture of sulphuric acid, the nitre is the most expensive article, many plans have been resorted to, for the purpose of obtaining the nitrous acid at a cheaper rate. One plan is to procure it by the igneous decomposition of nitre and dried sulphate of iron, and to pass it into a chamber already filled with sulphurous acid and atmospheric air, but devoid of water. After an interval of several hours, when the chamber is fully charged with the several gases, a certain quantity of steam from a boiler is allowed to enter with great force. This causes the formation of the sulphuric acid, which precipitates with the condensed steam on the floor of the chamber. Another method of obtaining nitrous acid is by treating molasses or starch with common nitric acid. In this case, the manufacturer obtains oxalic acid as a collateral product, which serves to diminish his expenses.

In most of the manufactories of sulphuric acid in France, nitrate of soda has been substituted for nitre. The advantages of the former salt are its greater cheapness, and the circumstance of its containing a larger proportional quantity of nitric acid.

The above explanations relate to the mode of preparing common sulphuric acid; but there is another kind known on the continent of Europe by the name of the *fuming sulphuric acid of Nordhausen*, so called from its properties, and a place in Saxony where it is largely manufactured. This acid is obtained by distilling dried sulphate of iron in large stoneware retorts, heated nearly to whiteness, and connected with receivers of glass or stoneware. The acid distils over, and peroxide of iron is left behind in the form of colcothar.

The process for making sulphuric acid by the combustion of sulphur with nitre, was first mentioned by Lemery, and afterwards put in practice by an English physician of the name of Ward. As practised by him, the combustion was conducted in very large glass vessels. About the year 1746, the great improvement of the leaden chambers was introduced by Dr. Roebuck, an eminent physician of Birmingham, where the first apparatus of this kind was erected; and in consequence of it, the acid immediately fell to one-fourth of its former price, and was introduced into many arts, from which it had been previously excluded by its expense. At the present day, immense quantities are manufactured in Great Britain, amounting, in 1823, according to a calculation of Mr. Parkes, to upwards of six millions of pounds.

In the United States, the first manufactory of this acid was established in Philadelphia by the late Mr. John Harrison. At present there are manufactories in successful operation in most of the large cities of the union. These supply the entire demand of the United States, no foreign acid being imported at the present day. The wholesale price of the acid varies from three and a half to four and a half cents per pound.

Properties. Sulphuric acid is a dense, colourless, inodorous liquid, having an oleaginous appearance, and possessing strong corrosive qualities. On the living fibre, it acts as a powerful caustic. Rubbed in small quantity between the fingers, it has an unctuous feel, in consequence of its dissolving the cuticle. In the liquid form, it always contains water, which is essential to its existence. When pure and as highly concentrated as possible, its sp. gr. is 1.8485, a fluidounce weighing a small fraction over fourteen drachms. Whenever its density exceeds this, the presence of sulphate of lead, or of some other impurity is indicated. It boils at 620°, and freezes at 15°. When diluted, its boiling point is lowered. When of the sp. gr. 1.78, it freezes at above 32°; and hence it is hazardous for manufacturers to keep an acid of that strength in glass vessels in cold weather, as they are liable to burst. With salifiable bases, it forms a numerous class of salts called sulphates. It acts powerfully on organic bodies, whether vegetable or animal, depriving them of the elements of water, developing charcoal, and turning them black. A small piece of cork or wood dropped into the acid, will, on this principle, render it of a dark colour. When diluted with pure water, it ought to remain limpid, and when heated sufficiently in a platinum spoon, it should evaporate without residue. When present in small quantities in solution, it is detected unerringly by muriate of baryta, which causes a precipitate of sulphate of baryta. The most usual impurities in it are the sulphates of potassa and lead, the former derived from the residue on the iron tray, the latter from the leaden boilers in which the acid is concentrated. It occasionally contains nitre, which is added to render dark acid colourless. These impurities often amount to 3 or 4 per cent. The commercial acid cannot be expected to be absolutely pure, but, when properly manufactured, it ought not to contain more than one per cent. of impurity. The fixed impurities are discoverable by evaporating a portion of the suspected acid, when they will remain. If sulphate of lead be present, the acid will become turbid by dilution.

Sulphuric acid, as it occurs in commerce and in the shops, is often under its standard strength; and hence it becomes important to know how much liquid sulphuric acid of the standard specific gravity, and of dry acid, is contained in an acid of any given density. The following table, drawn up from careful experiments by Dr. Ure, gives information of this kind. The mode of using it, is first to ascertain the specific gravity of any acid by experiment; and then, opposite to this specific gravity in the table, will be found the percentage of standard liquid acid and of dry acid contained in it.

Table of the Quantity of Liquid Sulphuric Acid of Sp. Gr. 1.8485, *and of Dry Acid, in* 100 *parts of Dilute Acid at different Densities.*

The only way to obtain pure sulphuric acid is by distillation. Owing to the high boiling point of this acid, the operation is rather precarious, in consequence of the danger of the fracture of the retort, from the sudden concussions to which the boiling acid gives rise. Dr. Ure recommends that a retort of the capacity of from two to four quarts be used in distilling a pint of acid. This is connected, by means of a wide glass tube three or four feet long, with a receiver surrounded with cold water. All the vessels must be perfectly clean, and no luting is employed. The retort is then to be cautiously heated by a small furnace of charcoal. It is useful to put into the retort a few sharp-pointed pieces of glass, or slips of platinum foil, with a view to diminish the shocks produced by the acid vapour. The distilled product ought not to be preserved until a dense grayish-white vapour is generated, the appearance of which is the sign that the real concentrated acid is coming over. If this vapour should not immediately appear, it shows that the acid subjected to distillation is not of full strength, and the distilled product, until the point of utmost concentration is attained, will be an acid water.

The Dublin College gives a formula for purifying the commercial acid by distillation. (See *Acidum Sulphuricum Purum.*) This formula, however, is unnecessary, as the commercial sulphuric acid, diluted with water, whereby it is purified from sulphate of lead, is sufficiently pure for medical use, while the pure distilled acid is only necessary in conducting experiments of research. The strong acid is not convenient for medicinal use, and hence a formula for a diluted acid is given in the United States Pharmacopœia, following the example of the British Colleges. (See *Acidum Sulphuricum Dilutum.*)

Incompatibles. Sulphuric acid is incompatible with most metals; with salifiable bases and their carbonates; with most salts, effecting their decomposition; with alcohol, which it converts into ether; with all organic substances, which it chars or otherwise decomposes; and with vegetable astringent infusions.

Composition. The ordinary liquid acid of the sp. gr. 1.8485, consists of one equivalent of dry acid 40.1, and one equiv. of water 9=49.1; and the dry acid, of one equiv. of sulphur 16.1, and three equiv. of oxygen 24=40.1. The liquid acid of Nordhausen has a density as high as 1.89 or 1.9, and consists of two equiv. of dry acid, and one equiv. of water. This acid is particularly adapted to the purpose of dissolving indigo for dyeing the Saxon blue. When heated gently in a retort, connected with a dry and refrigerated receiver, dry or anhydrous sulphuric acid distils over, and the common liquid acid remains behind. The anhydrous acid under 64° is in the form of small colourless crystals, resembling asbestos. It is tenacious, difficult to cut, and may be moulded in the fingers like wax, without acting on them. Exposed to the air, it emits a thick opaque vapour of an acid smell. Above 64° it is a liquid, very nearly of the density of 2. It has so strong an affinity for water, that when thrown into that liquid, it causes a hissing noise, like that produced by quenching red-hot iron.

Medical Properties. Sulphuric acid is tonic, antiseptic, and refrigerant. Internally it is always administered in a dilute state. (For its medical properties in this form, see *Acidum Sulphuricum Dilutum.*) Externally it is sometimes employed as a caustic; but, from its liquid form, it is very inconvenient for this purpose. It is applied also as an ointment mixed with lard, in swellings of the knee-joint and other affections, in the proportion of a drachm to an ounce. (See *Unguentum Acidi Sulphurici*, Dub.) Charpie, corroded by it, forms a good application to gangrene.

Toxicological Properties. The symptoms of poisoning by this acid are the following:—Burning heat in the throat and stomach; extreme fetidness of the breath; nausea, and excessive vomitings of black or reddish matter; excruciating pains in the bowels; difficulty of breathing; extreme anguish; a feeling of cold on the skin; great prostration; constant tossing; convulsions, and death. The intellectual faculties remain unimpaired. Frequently the uvula, palate, tonsils, and other parts of the fauces, are covered with black or white sloughs. The treatment consists in the administration of large quantities of magnesia, or if this is not at hand, of a solution of soap. The safety of the patient depends upon the greatest promptitude in the application of the remedies. After the poison has been neutralized, mucilaginous and other mild drinks must be taken in large quantities.

Uses in the Arts. Sulphuric acid is more used in the arts than any other acid. It is employed to obtain nearly all other acids; to extract soda from common salt; to make alum and sulphate of iron, when these salts command a good price, and the acid is cheap; to dissolve indigo; to prepare skins for tanning; and lastly, to prepare phosphorus, sulphuric ether, the chlorides of mercury, chloride of lime or bleaching salt, sulphate of zinc, and sulphate of magnesia. The arts of bleaching and dyeing principally cause its consumption.

ACIDUM TARTARICUM. *U.S., Lond., Dub.*

Tartaric Acid.

Acide tartrique, *Fr.;* Weinsteinsäure, *Germ.;* Acido tartarico, *Ital., Span.*

Tartaric acid is officinal in all the Pharmacopœias commented on in this work, except the Edinburgh. It is placed among the preparations by the London and Dublin Colleges; but stands more properly, in the United States Pharmacopœia, in the Materia Medica, as an article to be purchased from the wholesale manufacturer. It is extracted from tartar, a peculiar substance which concretes on the inside of wine-casks, being deposited there during the fermentation of the wine. Tartar, when purified, is the cream of tartar of the shops, and is found to be a supersalt, consisting of two equivalents of tartaric acid, and one equiv. of potassa. It is, therefore, in correct chemical language, a bitartrate of potassa. (See *Potassæ Supertartras.*)

Tartaric acid was first obtained in a separate state by Scheele in 1770. The process consists in saturating the excess of acid in the bitartrate of potassa with carbonate of lime, and decomposing the resulting soluble tartrate of lime by sulphuric acid, which precipitates in combination with the lime, and liberates the tartaric acid. The equivalent quantities are one equiv. of bitartrate, and one equiv. of carbonate of lime. The process, when thus conducted, furnishes the second equivalent or excess of acid only of the bitartrate. The other equivalent may be procured by decomposing the neutral tartrate of potassa remaining in the solution after the precipitation of the tartrate of lime, by muriate of lime in excess. By double decomposition, muriate of potassa will be formed, and a fresh portion of tartrate of lime, which latter is to be decomposed by sulphuric acid in the same manner as the first portion. The process, when thus conducted, will furnish, in theory, twice as much tartaric acid as when the excess of acid only is saturated and set free.

Preparation on the Large Scale. The mode of obtaining this acid on the large scale is as follows. Mix intimately, by grinding in a mortar and passing through a sieve, 100 parts, of bitartrate of potassa (cream of tartar) with 26½ parts of pulverized chalk. Throw the mixture, by spoonfuls, into 8 or 10 times its weight of boiling water, waiting until the effervescence has ceased, before every fresh addition. Examine the solution by litmus paper, and if not neutral, make it so, by the addition of a little chalk. Wash the tartrate of lime with abundance of cold water, and add to it a quantity of sulphuric acid equal in weight to the chalk employed, and diluted with from 10 to 16 times its weight of water. Agitate the mixture frequently for 24 hours, and then test a small portion of the clear solution for sulphuric acid by acetate of lead. A precipitate will be formed, which is either tartrate of lead, or a mixture of tartrate and sulphate of lead. If the former, it will dissolve entirely in dilute nitric acid; if the latter, only partially, as the sulphate of lead is insoluble in this acid. If a slight excess of sulphuric acid should be indicated, it is of no consequence; but if the excess be considerable, it must be removed by a fresh addition of chalk. On the other hand, an excess of tartrate of lime, which interferes very much with the crystallization of the tartaric acid, must be decomposed by adding a small quantity of sulphuric acid. The clear liquor, separated from the sulphate of lime, is concentrated by evaporation to the consistence of syrup, and allowed to crystallize. Repeated solutions and crystallizations are necessary to get the crystals white. The mode of ascertaining the quantity of chalk consumed, is to weigh out more than is necessary in the process, and, after the saturation has been completed, to weigh what is left. If the neutral tartrate of potassa be also converted into tartrate of lime in the manner already explained, the quantity of sulphuric acid for decomposition must be doubled. Sometimes the bitartrate of potassa is decomposed by lime, in which case the whole of the tartaric acid present is converted into tartrate of lime at one operation; but the caustic potassa, also liberated, by dissolving the tartrate of lime formed and preventing it from precipitating, renders this process ineligible.

The reader is now prepared to understand the formulæ of the London and Dublin Colleges.

"Take of supertartrate of potassa two pounds and a half; boiling distilled water three gallons; prepared chalk a pound; sulphuric acid a pound. Boil the supertartrate of potassa with two gallons of the distilled water, and add by degrees the prepared chalk, until effervescence shall have ceased. Set the mixture by, that the tartrate of lime may subside. Pour off the solution, and wash the tartrate of lime repeatedly with distilled water, until it comes off tasteless. Then pour on the sulphuric acid, diluted with a gallon of boiling distilled water, and set aside for twenty-four hours, occasionally agitating the mixture. Filter the liquor, and evaporate it in a water-bath, that crystals may form."—*Lond.*

"Take of bitartrate of potassa, reduced to powder, ten parts; prepared chalk, four parts; sulphuric acid seven parts; water, one hundred and twenty parts. Mix the bitartrate of potassa with one hundred parts of hot water, and gradually add the prepared chalk; then, as soon as the effervescence shall have ceased, pour off the supernatant liquor. Wash the residual tartrate of lime, until it becomes tasteless. Into the clear decanted liquor, drop as much of the water of muriate of lime as may be sufficient to throw down the tartrate of lime. Let this also be washed with water, and mixed with the former deposite. Then add the sulphuric acid, diluted with twenty parts of water, and, employing frequent agitation, digest the mixture with a *medium* heat during three days. Pour off the supernatant acid fluid, and wash out the acid from the sediment. Let the liquors, including the first acid liquor and the washings, evaporate with a gentle heat to the point of crystallization. Let the crystals, purified by repeated solutions and crystallizations, be kept in a stopped glass vessel."—*Dub.*

These processes agree in the proportions of bitartrate and chalk employed. The quantity of chalk directed appears to be excessive, being two-fifths of the weight of the bitartrate; whereas, by theory, a portion only one-fourth the weight of the latter is required; and making every allowance for impurities, one-third would be amply sufficient. The plan of dissolving the bitartrate in boiling water, and then adding the chalk, is not an eligible one. It is better to mix them together according to the plan given by Dr. Henry, as described in the beginning of this article, and to throw the mixture by spoonfuls at a time into boiling water. In this way, less water is necessary, and less excess of chalk is required, as less of it escapes decomposition. Instead of prescribing the quantity of chalk, it would, perhaps, have been an improvement, if the Colleges above quoted, had directed a quantity "sufficient for saturation." The London College uses the proper quantity of sulphuric acid, the best authorities directing that this acid should equal in weight the chalk employed, where the excess of acid only in the bitartrate is obtained. The Dublin College, it is perceived, decomposes the neutral tartrate, and would obtain, if no loss occurred, a double quantity of tartaric acid. The London College, however, makes no use of the solution of the neutral tartrate; but to prevent waste it ought to be evaporated so as to furnish soluble tartar. The process of the Dublin College is inaccurately quoted by the authors of the London and Edinburgh Dispensatories. Dr. A. T. Thomson has misapprehended the effect of the muriate of lime employed in the Dublin formula.

Nearly all the tartaric acid consumed in the United States is of domestic manufacture. Occasionally, however, a few kegs are imported from Bordeaux or Marseilles, when the article happens to command a good price.

Properties. Tartaric acid is a white crystallized solid in the form of irregular six-sided prisms. Sometimes two opposite sides of the prism become very much enlarged, so as to cause the crystals to present the appearance of tables. It is unalterable in the air, and possesses a strong acid taste, which becomes agreeable when the acid is sufficiently diluted with water. It is soluble in five or six times its weight of cold, and twice its weight of boiling water. It is also soluble in alcohol. A weak solution undergoes spontaneous decomposition by keeping, becoming covered with a mouldy pellicle. In the form of crystals, it always contains combined water, from which it cannot be separated without previous combination with a base. In uniting with bases, it has a remarkable tendency to form double salts, several of which constitute important medicines. When subjected to heat, it yields, in addition to the usual products of the destructive distillation of vegetable matter, a peculiar acid, called *pyrotartaric.* It is distinguished from all other acids by forming a precipitate, consisting of bitartrate of potassa, when added to a salt of that alkali. The most usual impurity in it is sulphuric acid, which is detected by the solution affording, with muriate of baryta, a precipitate insoluble in excess of muriatic acid.

Tartaric acid is incompatible with salifiable bases and their carbonates; with salts of potassa, with which it produces a crystalline precipitate of bitartrate; and with the salts of lime and of lead, with which it also forms precipitates. It consists, when dry, of two equivalents of hydrogen 2, four equiv. of carbon 24.48, and five equiv. of oxygen 40=66.48; and when crystallized, of one equiv. of dry acid 66.48, and one equiv. of water 9=75.48.

Medical Properties. Tartaric acid, being cheaper than citric acid, forms, when dissolved in water and sweetened, a good substitute for lemonade. It is very much used in medicine to form acid refrigerant drinks and effervescing draughts. What are called *soda powders*, consist of twenty-five grains of tartaric acid, and half a drachm of bicarbonate of soda, put up in separate papers. When used, the acid and salt are dissolved in separate portions of water, and the solutions mixed and drank in a state of effervescence. These powders furnish a good substitute for soda water. Tartaric acid is also a constituent in the gentle aperient called *Seidlitz powders.* These consist of a mixture of two drachms of tartrate of potassa and soda, (Rochelle salt,) and two scruples of bicarbonate of soda, put up in a white paper, and thirty-five grains of tartaric acid contained in a blue one. The contents of the white paper are dissolved in about half a pint of water, to which those of the blue paper are added; and the whole is taken in a state of effervescence. The excess of acid renders the medicine more pleasant, without injuring its aperient quality. This acid, when powdered and dried by a gentle heat, and then mixed in due proportion with the bicarbonate of soda, forms a good effervescing powder, a teaspoonful of which, stirred into a tumbler of water, forms the dose. The mixture must be kept in well stopped vials. The neutralizing power of tartaric acid is about the same as that of citric acid.

Tartaric acid is not employed in any officinal preparation. B.

ACONITUM, *U. S.*

Aconite.

"Aconitum Neomontanum. Folia. *The leaves.*" *U. S.*

Off. Syn. ACONITI FOLIA. Aconitum Napellus. Folia. *Lond.;* ACONITI NAPELLI FOLIA. *Ed.;* ACONITUM PANICULATUM. Folia. *Dub.*

Aconit, *Fr.;* Eisenhut, Mönchskappe, *Germ.;* Aconito, Napello, *Ital.;* Aconito, *Span.*

Aconitum. *Sex. Syst.* Polyandria Trigynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. *Petals* five, the highest arched. *Nectaries* two, peduncled, recurved. *Pods* three or five. *Willd.*

The plants belonging to this genus are herbaceous, with divided leaves, and violet or yellow flowers disposed in spikes, racemes, or panicles. In the French Codex three species are adopted as officinal, the *A. Anthora*, *A. Cammarum*, and *A. Napellus* of Linnæus. The London and Edinburgh Colleges recognise only the *A. Napellus*, which was erroneously supposed to be the plant employed by Störck, who introduced the medicine into notice. The U. S. Pharmacopœia follows Willdenow in adopting the *A. neomontanum* as the plant described by Störck. The Dublin College recognises only the *A. paniculatum* of De Candolle. This botanist, in his Prodromus, divides the genus *Aconitum* into four sections—*Anthora*, *Lycoctonum*, *Camarum*, and *Napellus*. The *A. paniculatum* belongs to the third of these divisions; and the particular plant, believed to have been used by Störck, is a variety of this species, distinguished in the Prodromus as the *Störckianum*. De Candolle is probably correct. The A. neomontanum of Willdenow for which the honour has been generally claimed, is, according to Geiger, possessed of little acrimony, and is therefore very different from Störck's plant, which is represented as extraordinarily acrid. It is, however, of little consequence which was used by Störck, as most of the species possess similar virtues, and one is frequently substituted for another in the shops. Geiger states that he has found none equal to the A. Napellus in acrimony; and this may, therefore, perhaps, be considered as the most efficacious. Only one species of aconite is indigenous in this country—the *A. uncinatum.* Most of the others are natives of the Alpine regions of Europe and Siberia. Those employed in medicine appear to be indiscriminately called by English writers *wolfsbane* or *monkshood.*

Aconitum Napellus. Linn. *Flor. Suec. ed.* 1755, p. 186.—*A. neubergense.* De Cand. *Syst. veg.* i. 373.—*A variabile neubergense.* Hayne, *Darstel. und Beschreib.* &c., xii. 14. This is a perennial herbaceous plant, with a turnip-shaped or fusiform root, and an erect, round, smooth, leafy stem, which is usually simple, and rises from two to four feet, sometimes even six or eight feet in height. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions, the upper, short footstalks and three or five divisions. The divisions are narrow at their base, but widen in the form of a wedge towards their summit, and present two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the laciniæ or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue colour, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes rise from the axils of the upper leaves. Though without calyx, they have two small calycinal stipules situated on the peduncle within a few lines of the flower. The petals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two pedicled nectaries, of which the spur is capitate, and the lip bifid and revolute. The fruit consists of three, four, or five podlike capsules.

The plant is abundant in the mountainous forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental flower. All parts of it are acrid and poisonous; but the leaves only are officinal. They should be collected when the flowers begin to appear, or shortly before.

Properties. The fresh leaves have a faint narcotic odour, which is most sensible when they are rubbed. Their taste is at first bitterish and herbaceous, afterwards burning, very acrid, and durable. When long chewed, they inflame the tongue. The dried leaves have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. They should be of a green colour and neither musty nor tasteless. Those parcels should always be rejected which are destitute of acrimony. Other species of aconite are often substituted, and, if possessed of the same sensible properties, without inconvenience. The analysis of aconite, though attempted by several chemists, has not been satisfactorily accomplished. Bucholz obtained from the fresh herb of the A. neomontanum, resin, wax, gum, albumen, extractive, lignin, malate and citrate of lime and other saline matters, besides 83.33 per cent. of water. During the bruising of the herb, he experienced headach, vertigo, &c., though water distilled from it produced no poisonous effect. It has been rendered probable by the researches of Geiger and Hesse, that there are two active principles in aconite, one easily destructible, upon which the acrimony depends, the other but slightly acrid, having alkaline properties, and capable of exerting a powerful narcotic influence over the system. For the latter, the name of *aconitin* has been proposed; which, however, if the claim of the principle to the rank of an alkali be admitted, should be changed to *aconitia.* Hesse obtained it from the dried leaves by a process similar to that employed in procuring atropia. (See *Belladonna.*) Dr. Turnbull recommends the following process, as affording it in a state of considerable purity. The alcoholic extract of the root prepared by a cautious evaporation is to be treated with water, and the aqueous solution filtered. To the filtered solution, water of ammonia is to be added drop by drop, so long as any precipitate is produced. When the precipitate has subsided, the supernatant liquid is to be drawn off, and the residual mass washed repeatedly with small quantities of cold water, and then dried. (*Lond. Med. and Surg. Journ., Feb.* 1835.) *Aconitia* is white, uncrystallizable, inodorous, and of a bitter, somewhat acrid taste, though its acrimony is much weaker and less permanent than that of the plant itself. Unless very pure, it is apt to be associated with a portion of the acrid principle, from which it can be wholly freed only by repeatedly dissolving it in a diluted acid, and precipitating by means of an alkali. It is fusible without being volatile, is scarcely soluble in water, but very soluble in alcohol, and is dissolved by ether. It neutralizes the acids, producing with them salts which appear to be uncrystallizable. In its operation on the animal system, it is exceedingly powerful; one-fiftieth of a grain having sufficed to kill a small bird. (*Annalen der Pharmacie*, 1833.) Dr. Turnbull states that twenty drops of an alcoholic solution containing one grain to the drachm, put into the mouth of a guinea pig, produced death in a few minutes. Peschier has announced the existence of a peculiar acid in aconite, which he calls *aconitic acid.*

Medical Properties and Uses. Aconite was well known to the ancients as a powerful poison, but was first employed as a medicine by Baron Störck of Vienna, whose experiments with it were published in the year 1762. In moderate doses it excites the circulation, increases the perspiratory and urinary discharge, and exercises considerable influence over the nervous system. When given in poisonous doses, it occasions burning heat of the stomach, thirst, violent nausea, vomiting, purging, severe gastric and intestinal spasms, vertigo, mania, convulsions, and death. Its constitutional effects are also experienced when it is applied to the surface of a wound. Orfila inferred from his experiments, that, while it irritates the part to which it is applied, it also enters the circulation and acts powerfully on the nervous system, particularly the brain, giving rise to a species of mental alienation. Dissection reveals inflammation of the stomach and bowels, with engorgement of the brain and lungs. Aconite has been employed in rheumatism, gout, scrofula, secondary syphilis, scirrhus and cancer, certain cutaneous diseases, amaurosis, paralysis, epilepsy, intermittent fever, and other complaints. Its highest reputation has perhaps been as a remedy in obstinate rheumatism, in which complaint it has been very successful in the hands of the German practitioners. Professor Fouquier, who experimented largely with it in the *Hôpital de la Charité*, found little advantage from its use, except as a diuretic in passive dropsy. It may be administered in powder, extract, or tincture. The dose of the powdered leaves is one or two grains; that of the extract from half a grain to a grain, to be repeated twice or three times a day, and gradually increased till the effects of the medicine are experienced. The tincture may be prepared by macerating two ounces of the dried leaves in a pint of alcohol, and may be given in the dose of ten or fifteen drops, to be gradually augmented. Aconite is little used by American practitioners.

Aconitia has been employed externally in neuralgia, and in gouty and rheumatic affections. According to Dr. Turnbull, it excites a sensation of heat and prickling in the part, succeeded by a feeling of numbness and constriction, which lasts several hours; but little or no vascular irritation is produced. An alcoholic solution containing one grain in a fluidrachm, or an ointment composed of two grains of aconitia, six drops of alcohol, and a drachm of lard, may be applied, in small portions, by friction, to the part affected, three or four times a day; the proportion of the alkali being gradually increased as the occasion may demand. Care should be taken that the cuticle be not abraded, as dangerous constitutional effects might otherwise result.

Axonge, Graisse, Saindoux, *Fr.;* Schweineschmalz, *Germ.;* Grasso di porco, Lardo, *Ital.;* Manteca de puerco, Lardo, *Span.*

Lard is the prepared fat of the hog. The London and Dublin Colleges give processes for its preparation; but as in this country it is purchased by the druggists already prepared, the introduction of any officinal directions into our Pharmacopœia was deemed superfluous. The adipose matter of the omentum and mesentery, and that which surrounds the kidneys, are usually employed; though the subcutaneous fat is said to afford lard of a firmer consistence. In the crude state it contains membranes and vessels, and is more or less contaminated with blood, from all which it must be freed before it can be fit for use. For this purpose, the fat, having been deprived as far as possible, by the hand, of membranous matter, is cut into pieces, washed with water till the liquid ceases to be coloured, and then melted, usually with a small portion of water, in a copper or iron vessel, over a slow fire. The heat is continued till all the moisture is evaporated, which may be known by the transparency of the melted fat, and the absence of crepitation when a small portion of it is thrown into the fire. Care should be taken that the heat is not too great, as otherwise the lard might be partially decomposed, acquire a yellow colour, and become acrid. The process is completed by straining the fluid through linen, and pouring it into suitable vessels, in which it concretes upon cooling.

Lard, as offered for sale, often contains common salt, which renders it unfit for pharmaceutic purposes. To free it from this, the Dublin College directs that it be melted with twice its weight of boiling water, the mixture well agitated and set aside to cool, and the fat then separated.

Properties. Lard is white, inodorous, with little taste, of a soft consistence at ordinary temperatures, fusible at about 100° F., insoluble in water, partially soluble in alcohol, dissolved and decomposed by the stronger acids, and converted into soap by union with the alkalies. According to Braconnot, it contains, in 100 parts, 62 of *elaïn* or the liquid principle of oils, and 38 of *stearin* or the concrete principle. Most fats and oils, whether of animal or vegetable origin, are composed of these two ingredients, upon the relative proportion of which their consistence respectively depends. They may be obtained separate by the action of boiling alcohol, which on cooling deposites the stearin, and yields the elaïn upon evaporation. Another method is to compress fat, or oil congealed by cold, within the folds of bibulous paper. The elaïn is absorbed by the paper, and may be separated by compression under water; the stearin remains.

Elaïn resembles oil in appearance, is colourless when pure, congeals at 20° F., may be evaporated unchanged *in vacuo*, has little odour and a sweetish taste, is insoluble in water but soluble in boiling alcohol, and consists of carbon, oxygen, and hydrogen.

Stearin is white, concrete, fusible at 111° F., volatilizable unchanged *in vacuo*, partly volatilized and partly decomposed when heated in a retort, insipid, inodorous, slightly soluble in alcohol, insoluble in water, and composed, like the former principle, of carbon, hydrogen, and oxygen.*

Exposed to the air, lard absorbs oxygen and becomes rancid. It should therefore be kept in well closed vessels, or procured fresh when wanted for use. In the rancid state it is irritating to the skin, and sometimes exercises an injurious reaction on substances mixed with it. Thus the ointment of iodide of potassium, which is white when prepared with fresh lard, is said to be more or less yellow when the lard employed is rancid.

Medical Properties and Uses. Lard is emollient, and is occasionally employed by itself in frictions, or in connexion with poultices to preserve their soft consistence; but its chief use is in pharmacy as an ingredient of ointments and cerates. It is frequently added to laxative enemata.

# ALCOHOL. *U. S.*

Alcohol.

SPIRITUS RECTIFICATUS. *Lond., Dub.;* ALCOHOL FORTIUS. *Ed.*

Spirit of wine; Alcool, Esprit de vin, *Fr.;* Rectificirter Weingeist, *Germ.;* Alcoole, Acquavite rettificata, *Ital.;* Alcohol, Espiritu rectificado de vino, *Span.*

Considerable confusion prevails in the nomenclature adopted in the different Pharmacopœias, to express the various pharmaceutical strengths of the liquid, which in its pure state is known to the chemist under the name of alcohol. The London and Dublin Colleges have adopted three strengths of this substance; while the Edinburgh and United States Pharmacopœias have admitted only two. The following table presents a synoptic view of the names and strengths of the alcohol according to these different authorities; assuming those preparations to be identical, the specific gravities of which approach to an equality.

	U. S.	*Lond.*	*Dub.*	*Ed.*
Highest off. strength.	—	Alcohol. Sp. gr. 0.815	Alcohol. Sp. gr. 0.810	—
Medium do.	Alcohol. Sp. gr. 0.835	Spiritus Rectificatus. Sp. gr. 0.835	Spiritus Rectificatus. Sp. gr. 0.840	Alcohol Fortius. Sp. gr. 0.835
Lowest do.	Alcohol Dilutum.	Spiritus Tenuior. Sp. gr. 0.930.	Spiritus Tenuior. Sp. gr. 0.919	Alcohol Dilutius. Sp. gr. 0.935

Thus it is perceived that the officinal "Alcohol" of the United States Pharmacopœia, is a rectified spirit of the sp. gr. 0.835; while the spirit under the same officinal name, of the London and Dublin Colleges, is much stronger. It is certainly to be regretted that the same name has been applied to the substance of such different strengths, as it leads to confusion. Our principal object, however, in this article, is to describe the *alcohol* of the United States Pharmacopœia, corresponding to the London and Dublin *Spiritus Rectificatus*, and the Edinburgh *Alcohol Fortius;* and we shall introduce incidentally the formulæ for the stronger spirit of the London and Dublin Colleges, called by the same name. The *Alcohol Dilutum*, and the corresponding preparations of the British Pharmacopœias, will be considered in their appropriate place, in the second part of this work. (See *Alcohol Dilutum.*)

---

* From recent experiments by M. Le Canu it appears, that the concrete portion of animal oils to which the name of stearin has hitherto been applied, consists, in fact, of two distinct principles, distinguished by their different fusibility and solubility in ether. For that which is most fusible and most soluble in ether, he proposes the name of *margarin,* while for the other he retains the appellation before given to the mixture of the two.

Alcohol, in the chemical sense, is a peculiar liquid, generated for the most part in vegetable juices and infusions by a peculiar fermentation, called the vinous or alcoholic. The liquids which have undergone it are called vinous liquors, and are of various kinds. Thus the fermented juice of the grape is called wine; of the apple, cider; and the fermented infusion of malt, beer. All these, and many others, are vinous liquors, and for that reason contain alcohol.

With regard to the nature of the liquids susceptible of the vinous fermentation, one general character runs through them all, however various they may be in other respects, that, namely, of containing sugar in some form or other. It is found further, that after they have undergone the vinous fermentation, the sugar they contained has, either wholly or in part, disappeared, and that the only new products are alcohol which remains in the liquid, and carbonic acid which escapes during the process; and these, when taken together, are found to be equal in weight to the sugar which has disappeared. It is hence inferred, with much appearance of probability, that sugar is the subject matter of the vinous fermentation, and that during the change, it is resolved into alcohol and carbonic acid. Additional facts in support of this view, will be adduced under the head of the composition of alcohol.

Sugar, however, will not undergo the vinous fermentation by itself; but requires to be dissolved in water, subjected to the influence of a ferment, and kept at a certain temperature. Accordingly, sugar, water, the presence of a ferment, and the maintenance of an adequate temperature, may be deemed the prerequisites of the vinous fermentation. The water acts by giving fluidity, and the ferment and temperature operate by commencing and maintaining the chemical changes. The precise manner in which the ferment operates in commencing the reaction is not known. Neither has it been certainly ascertained whether it is a peculiar vegetable principle, or whether a number of distinct vegetable substances are capable of acting in a similar way. As a general rule, substances containing nitrogen, such as gluten, albumen, caseous matter, &c., possess the property of inducing the vinous fermentation. The proper temperature ranges from 60° to 90°.

Certain vegetable infusions, as those of potatoes and rice, though consisting almost entirely of starch, are, nevertheless, capable of undergoing the vinous fermentation, and form seeming exceptions to the rule that sugar is the only substance susceptible of this fermentation. The apparent exception is explained by the circumstance, that starch is susceptible of a spontaneous change which converts it into sugar. How this change takes place is not well known, but it is designated by some authors as the *saccharine* fermentation. Thus Kirchoff proved, that if a mixture of gluten from flour, and starch from potatoes, be put into hot water, the starch will be converted into sugar. When, therefore, starch is apparently converted into alcohol by fermentation, it is supposed that during the change it passes through the intermediate state of sugar.

Alcohol, being the product of the vinous fermentation, necessarily exists in all vinous liquors, and may be obtained from them by distillation. Formerly it was supposed that these liquors did not contain alcohol, but were merely capable of furnishing it in consequence of a new arrangement of their ultimate constituents, the result of the heat applied in the distillation. Brande, however, disproved this idea, by showing that alcohol may be obtained from all vinous liquors without the application of heat, and, therefore, must preexist in them. His method consists in precipitating their acid and colouring matter by subacetate of lead, and separating the water by carbonate of potassa. Gay-Lussac and Donovan have proved the same fact. According to the former, litharge in fine powder is the best agent for precipitating the colouring matter.

In vinous liquors, the alcohol is diluted with abundance of water, and associated with colouring matter, volatile oil, extractive, and various acids and salts, their nature and number depending upon the source of the liquor. In purifying it we take advantage of its volatility, which enables us to separate it by distillation, combined with some of the principles of the vinous liquor employed, and more or less water. The distilled product of vinous liquors forms the different varieties of ardent spirit of commerce. When obtained from wine, it is called brandy; from fermented molasses, rum; from cider, malted barley, or rye, whiskey; from malted barley and rye-meal with hops, and rectified from juniper berries, Holland gin; from malted barley, rye, or potatoes, rectified with turpentine, common gin; and from fermented rice, arrack. These spirits are of different strengths, that is, contain different proportional quantities of alcohol, and have various peculiarities by which they are distinguished by the palate. Their strengh is accurately judged of by the specific gravity, which is always inversely proportional to their concentration. When they have a sp. gr. of 0.920 they are designated in commerce by the term proof spirit. If lighter than this, they are said to be above proof; if heavier, below proof. *Proof spirit* may be considered as corresponding with the average strength of the weaker alcohol used in pharmacy. (See *Alcohol Dilutum.*)

Proof spirit is still very far from being pure; being a dilute alcohol, containing about half its weight of water, together with essential oil and other foreign matters. It may be further purified and strengthened by redistillation, or *rectification* as it is called. Whiskey is the spirit usually employed for this purpose, and from every hundred gallons, between fifty-seven and fifty-eight will be obtained, of the average strength of rectified spirit, (sp. gr. 0.835.) corresponding to the *alcohol* of the U. S. Pharm., and the *Spiritus Rectificatus* of the Lond. and Dub. Colleges. When this is once more cautiously distilled, it will be further purified from water, and attain the sp. gr. of about 0.825, which is the lightest spirit which can be obtained by ordinary distillation. It still, however, contains eleven per cent. of water. In the mean while, the spirit, by these repeated distillations, becomes more and more freed from essential oil.

If it be desired to obtain alcohol of still greater concentration, it is necessary to avail ourselves of certain substances which have a powerful affinity for water. Of this nature are lime, carbonate of potassa, and chloride of calcium. These being mixed with the rectified spirit, unite with water and sink, while the purer spirit floats above, and may be separated by decantation or distillation. By availing themselves of substances of this nature, the London and Dublin Colleges are enabled to produce their strongest spirit, which they denominate *alcohol.* (See tabular view page 52.) The following are the processes which they adopt.

ALCOHOL, (sp. gr. 0.815,) *Lond.*—"Take of rectified spirit, *a gallon;*

subcarbonate of potassa, *three pounds.* To the spirit add *a pound* of the subcarbonate of potassa, previously heated to 300°, and allow the mixture to macerate for twenty-four hours, with frequent agitation. Then, having poured off the spirit, add to it the remaining subcarbonate, heated to the same degree. Finally, by means of a water-bath, distil the alcohol, and keep it in stopped bottles."

Alcohol, (sp. gr. 0.810,) *Dub.*—"Take of rectified spirit, *a gallon;* pearlashes, dried and still hot, *three pounds and a half;* muriate of lime, dried, *a pound.* Add the pearlashes in powder to the spirit, and let the mixture digest in a covered vessel for seven days, shaking it frequently. Draw off the supernatant spirit, and mix with it the muriate of lime. Lastly, distil, with a moderate heat, until the mixture in the retort begins to thicken."

The alkali used in both these processes, is the carbonate of potassa, (improperly called subcarbonate in the London formula,) which is a very deliquescent salt, and consequently well fitted to abstract the water from alcohol. The chloride of calcium, (dry muriate of lime,) used by the Dublin College, is an agent of a similar kind, and for the same reason. The London College uses the carbonate only, and that in two portions; while the second addition of the Dublin, is of chloride of calcium. The Dublin formula is to be preferred, on account of the superior *deaquating* power of chloride of calcium, which, moreover, from its solubility in alcohol, comes in contact, as Dr. Barker of Dublin very justly remarks, with every particle of the water.

Alcohol, thus obtained, still contains a small proportion of water, to separate which, it must be very carefully and repeatedly distilled from chloride of calcium, or some other substance having a powerful attraction for water. When thus treated, it is finally brought to the sp. gr. 0.796, at the temp. of 60°, which is considered its point of greatest concentration, as it is now entirely free from water of dilution. In this state, it is called *absolute alcohol.*

Absolute alcohol may be obtained, on a small scale, by the ingenious method of Mr. Graham of Edinburgh. It consists in supporting a cup, containing a few ounces of common alcohol, over a shallow basin, covered to a small depth with lime. The whole is placed on the plate of an air-pump under a shallow receiver, and the air exhausted. The exhaustion causes a mixed atmosphere of the vapours of alcohol and water to arise, the latter of which only is absorbed by the lime. Its absorption permits fresh portions of watery vapour to be formed, which are absorbed in their turn, and the emission and absorption of the aqueous vapour continue so long as any water remains in the alcohol. In the mean time, the permanent atmosphere of alcoholic vapour effectually represses its fresh formation. Common spirit may thus be brought to the state of absolute alcohol in the course of five or six days. A good way for ascertaining when all the water has been removed, is to drop into the liquid a piece of anhydrous baryta, which will remain unchanged if the alcohol be free from water; otherwise it will fall to powder.

Properties. Alcohol is a colourless transparent liquid, of a penetrating, agreeable odour, and a burning and highly pungent taste. When free from water of dilution, its sp. gr. is 0.796, at the temp. of 60°. Its density progressively increases by dilution, so that its sp. gr. is an index of its strength. When of the sp. gr. 0.820, its boiling point is at 176°; this point being always lower in proportion as the alcohol is stronger. Its specific gravity, as a vapour, is 1.60 compared with air. It has never been congealed, having been exposed to the greatest artificial cold yet produced, (91° below zero,) without losing its liquidity. On account of this property, it is used in thermometers for measuring very low temperatures. It is inflammable, and burns without smoke or residue, the products being water, and carbonic acid. Its flame is of a bluish colour when the alcohol is strong; but yellowish, when weak. It combines with water in all proportions, forming mixtures which are variously denominated in commerce. Its value depends upon the quantity of absolute alcohol which it contains; and as this is greater in proportion as the sp. gr. of any sample is less, it is found convenient to take the density in estimating its purity. This is done by instruments with bulbs and long stems, called hydrometers, which, by being allowed to float in the spirit, sink deeper into it in proportion as it is lighter. Any given hydrometer strength corresponds with some particular specific gravity; and by referring to tables constructed for the purpose, the percentage of absolute alcohol indicated in each case is at once shown. The following table constructed by Lowitz and improved by Thomson, is of this kind. We have placed in notes, referring to their respective specific gravities in the table, the names of the different officinal spirits, whereby the percentage of absolute alcohol is indicated which they severally contain.

Table of the Specific Gravity of different mixtures of Absolute Alcohol and Distilled Water, at the Temp. of 60°.

Alcohol is capable of dissolving a great number of substances; as for example, sulphur and phosphorus in small quantity; iodine; ammonia; and potassa, soda, and lithia in the caustic state, but not as carbonates. Among vegetable substances, it is a solvent of the organic vegetable alkalies, sugar, mannite, camphor, resins, balsams, volatile oils, and soap. It dissolves the fixed oils sparingly, except castor oil, which is abundantly soluble. It acts on most acids, forming ethers with some, and effecting the solution of others. All deliquescent salts are soluble in alcohol, except carbonate of potassa; while the efflorescent salts, and those either insoluble or sparingly soluble in water, are mostly insoluble in it.

---

* Alcohol, *Dub.* (nearly.) † Alcohol, *Lond.* ‡ Lightest spirit obtained by ordinary distillation. § Alcohol, *U.S.;* Spiritus Rectificatus, *Lond.;* Alcohol Fortius, *Ed.* ‖ Spiritus Rectificatus. *Dub.* ¶ Spiritus Tenuior, *Dub.* (nearly.) ** Spiritus Tenuior, *Lond.* †† Alcohol Dilutius, *Ed.*

It is capable of combining, in the solid form, with different substances, so as to form definite compounds, which, from their analogy to hydrates, are called *alcoates.*

Composition. Alcohol consists of three equivalents of hydrogen 3, two equiv. of carbon 12.24, and one equiv. of oxygen 8 = 23.24; or in volumes, of three volumes of hydrogen, two volumes of the vapour of carbon, and half a volume of oxygen. These ultimate constituents are considered by the generality of chemists to be so combined as to form one equiv. of olefiant gas 14.24, and one equiv. of water 9; corresponding to one volume of olefiant gas, and one volume of the vapour of water, which are condensed into one volume of alcohol vapour.

Some chemists view the equivalent number of alcohol as double that given above, or 46.48. Those who take this view consider it as a compound of one equiv. of etherine 28.48, and two equiv. of water 18; or in volumes, of one volume of etherine and two volumes of the vapour of water, condensed into two volumes. *Etherine* is a highly volatile liquid, discovered by Faraday, consisting of four equiv. of carbon 24.48, and four of hydrogen 4 = 28.48; or of four volumes of vapour of carbon, and four of hydrogen condensed into one volume of its vapour. It is hence obvious that etherine is *isomeric* with olefiant gas, and only differs from it in having an equivalent exactly double, and in being, in a state of vapour, twice as dense.

It has been already stated, that in the vinous fermentation, sugar is converted into alcohol and carbonic acid. Now sugar consists, according to the analysis of Dr. Prout, of one equiv. of hydrogen, one of carbon, and one of oxygen; and carbonic acid consists of one equiv. of carbon and two of oxygen. Bearing in mind these data, as also the composition of alcohol, it is easy to explain how sugar may be resolved into alcohol and carbonic acid. If, in order to equalize the hydrogen in the sugar and alcohol respectively, we suppose three equiv. of sugar to be the subject-matter of decomposition, we shall have present in that quantity of it, three equiv. of hydrogen, three of carbon, and three of oxygen. Now, if from these we take one equiv. of carbon and two of oxygen—that is, carbonic acid—we shall have left three equiv. of hydrogen, two of carbon, and one of oxygen, or the exact constituents of alcohol. Thus the composition of the several substances concerned most fully confirms the statement previously made as to the subject-matter and products of the vinous fermentation.

Medical Properties, &c. Alcohol is a very powerful diffusible stimulant. It is the intoxicating ingredient in all spirituous and vinous liquors, including under the latter term porter, ale, and cider, and every liquid in short which has undergone the vinous fermentation. In its pure state it is never used in medicine; but diluted to various degrees, it forms a menstruum for many remedies. In a diluted state, and taken in small quantity, it excites the system, renders the pulse full, communicates additional energy to the muscles, and gives temporary exaltation to the mental faculties. In some states of acute disease, characterized by excessive debility, it is a valuable remedy. In the form of brandy, it is frequently given in the sinking stages of typhus with advantage. Other kinds of ardent spirit are occasionally administered, and each is supposed to have its peculiar qualities.

Thus, according to Dr. Paris, brandy may be esteemed simply cordial and stomachic; rum, heating and sudorific; and gin and whiskey, diuretic. Physicians should be on their guard not to prescribe alcoholic remedies in chronic diseases, whether alone or in the form of tinctures, for fear of begetting habits of intemperance in their patients. Externally, alcohol is sometimes applied to produce cold by evaporation, or to stimulate when its evaporation is repressed.

As an article of daily and dietetic use, alcoholic liquors produce the most deplorable consequences. Besides the moral degradation which they cause, their habitual use gives rise to dyspepsia, hypochondriasis, visceral obstructions, dropsy, paralysis, and not unfrequently mania.

Alcohol is extensively employed by perfumers and distillers, in making essences and cordials. In the arts it is used to form drying varnishes, and in chemistry, as an important analytic agent. Being a powerful antiseptic, it is very useful in preserving anatomical preparations.

Effects as a Poison. When taken in a large quantity, alcohol, in the form of various ardent spirits, produces a true apoplectic state, and occasionally speedy death. The face becomes livid or pale, the respiration stertorous, the mouth frothy; and sense and feeling are more or less completely lost. Where the danger is imminent, an emetic may be administered. The affusion of cold water is often very useful. As a counter-poison, acetate of ammonia has been asserted to act with advantage.

Pharmaceutic Uses. Alcohol is very extensively employed as a pharmaceutic agent. Either in its rectified state, or diluted with water, it is used in the formation of all the tinctures, spirits, ethers, and resinous extracts; is added to the vinegars, some of the medicated waters, and one or more of the decoctions and infusions, to assist in their preservation; serves as a vehicle or diluent of certain active medicines, as in the *Alcohol Ammoniatum*, and *Acidum Sulphuricum Aromaticum;* and is employed for various incidental purposes connected with its solvent power.

ALETRIS. *U.S. Secondary.*

Star Grass.

"Aletris farinosa. Radix. *The root.*" *U.S.*

ALETRIS. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Asphodeleæ.

Gen. Ch. *Corolla* tubular, six-cleft, wrinkled, persistent. *Stamens* inserted into the base of the segments. *Style* triangular, separable into three. *Capsule* opening at the top, three-celled, many seeded. *Bigelow.*

Aletris farinosa. Willd. *Sp. Plant.* ii. 183; Bigelow, *Am. Med. Bot.* iii. 92. This is an indigenous perennial plant, the leaves of which spring immediately from the root, and spread on the ground in the form of a star. Hence have originated the popular names of *star grass*, *blazing star*, and *mealy starwort*, by which it is known in different parts of the country. The leaves are sessile, lanceolate, entire, pointed, very smooth, longitudinally veined, and of unequal size, the largest being about four inches in length. From the midst of them a flower stem rises, one or two feet in height, nearly naked, with remote scales, which sometimes become leaves. It terminates in a slender scattered spike, the flowers of which stand on very short pedicels, and have minute bractes at the base. The calyx is wanting. The corolla is tubular, oblong, divided at the summit into six spreading segments, of a white colour, and presenting, when old, a mealy or rugose appearance on the outside. The plant is found in almost all parts of the U. States, growing in fields and about the borders of woods, and flowering in June and July.

Properties. The root, which is the officinal portion, is small, crooked, branched, blackish externally, brown within, and intensely bitter. The bitterness is extracted by alcohol, and the tincture becomes turbid upon the addition of water. The decoction is moderately bitter; but much less so than the tincture. It affords no precipitate with the salts of iron.—(*Bigelow.*)

Medical Properties. In small doses the root appears to be simply tonic, and may be employed advantageously for similar purposes with other bitters of the same class. When largely given it produces nausea. The powder may be administered as a tonic in the dose of ten grains. W.

ALLIUM. *U.S.*

Garlick.

"Allium sativum. Bulbus. *The Bulb.*" *U.S.*

Off. Syn. ALLII RADIX. Allium sativum. Radix. *Lond.;* ALLII SATIVI RADIX. *Ed.;* ALLIUM SATIVUM. Bulbus. *Dub.*

Ail, *Fr.;* Knoblauch, *Germ.;* Aglio, *Ital.;* Ajo, *Span.*

Allium. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Asphodeleæ.

Gen. Ch. *Corolla* six-parted, spreading. *Spathe* many-flowered. *Umbel* crowded. *Capsule* superior. *Willd.*

This is a very extensive genus, including more than sixty species, most of which are European. Of the nine or ten indigenous to this country, none are employed. Of the European species, several have been used from a very early period, both as food and medicine. Three only are officinal; the *A. sativum*, or garlick; the *A. Cepa*, or onion; and the *A. Porrum*, or leek. The U. S. Pharmacopœia has adopted only the *A. sativum*, and to this we shall confine our observations in the present place, simply stating that few genera present a greater resemblance in medical and sensible properties among the various species that compose them, than the present.

Allium sativum. Willd. *Sp. Plant.* ii. 68; Woodv. *Med. Bot.* p. 749, t. 256. This is a perennial plant, and like all its congeners, bulbous. The bulbs are numerous, and enclosed in a common membranous covering, from the base of which the fibres that constitute the proper root descend. The stem is simple, and rises about two feet in height. The leaves are long, flat, and grass-like; and sheath the lower half of the stem. At the termination of the stem is a cluster of flowers and bulbs mingled together, and enclosed in a pointed spathe which opens on one side and withers. The flowers are small and white, and make their appearance in July. This species of garlick grows wild in Sicily, Italy, and the South of France; and is cultivated in all civilized countries.

The part employed as well for culinary purposes as in medicine, is the bulb, which is properly designated in the U. S. Pharmacopœia. The London and Edinburgh Colleges erroneously direct the root, which, though in ordinary language confounded with the bulb, is, in fact, botanically speaking, composed of the fibres that proceed from its base. The bulbs are dug up with a portion of the stem attached, and, having been dried in the sun, are tied together in bunches, and thus brought into market. They are said to lose by drying nine parts of their weight out of fifteen, with little diminution of their sensible properties. This species of Allium is commonly called *English garlick*, to distinguish it from those which grow wild in our fields and meadows.

Properties. Garlick, as found in the shops, is of a shape somewhat spherical, flattened at the bottom, and drawn towards a point at the summit, where a portion of the stem several inches in length projects. It is covered with a white, dry, membranous envelope, consisting of several delicate laminæ, within which the small bulbs are arranged around the stem, having each a distinct coat. These small bulbs, which in common language are called *cloves* of garlick, are usually five or six in number, of an oblong shape, somewhat curved, and in their interior are whitish, moist, and of a fleshy consistence. They have a disagreeable pungent odour, so peculiar as to have received the name of *alliaceous*. Their taste is bitter and acrid. This smell and taste, though strongest in the bulb, are found to a greater or less extent in all parts of the plant. They depend on an *essential oil* which is very volatile, and may be obtained by distillation, passing over with the first portions of water. It is of a yellow colour, exceedingly pungent odour, strong and acrid taste; is heavier than water; and when applied to the skin produces much irritation, and sometimes even blisters. Besides this oil, fresh garlick, according to Cadet-Gassicourt, contains in 1406 parts, 520 of mucilage, 37 of albumen, 48 of fibrous matter, and 801 of water. Bouillon-Lagrange mentions among its constituents, sulphur, a saccharine matter, and a small quantity of fecula. The fresh bulbs yield upon pressure nearly a fourth part of juice, which is highly viscid, and so tenacious as to require dilution with water before it can be easily filtered. When dried it serves as a lute for porcelain. It has the medical properties of the bulbs. Water, alcohol, and vinegar extract the virtues of garlick. Boiling, however, if continued for some time, renders it inert.

Medical Properties and Uses. The use of garlick as a medicine and condiment, ascends to the highest antiquity. When taken internally, its active principle is very speedily absorbed, and penetrating throughout the system, becomes sensible in the breath and various secretions. Even externally applied, as for example to the soles of the feet, it imparts its peculiar odour to the breath, urine, and perspiration, and according to some writers, may be tasted in the mouth. Its effects upon the system are those of a general stimulant. It quickens the circulation, excites the nervous system, promotes expectoration in a debilitated state of the vessels of the lungs, produces diaphoresis or diuresis according as the patient is kept hot or cool, and acts upon the stomach as a tonic and carminative. Applied to the skin, it is irritant and rubefacient, and moreover exercises to a greater or less extent, its peculiar influence upon the system, in consequence of its absorption. Moderately employed, it is beneficial in enfeebled digestion and flatulence; and is habitually used as a condiment by many who have no objection to an offensive breath. It has been given with advantage in chronic catarrh, humoral asthma, and other pectoral affections in which the symptoms of inflammation have been subdued, and a feeble condition of the vessels remains. Some physicians have highly recommended it in old atonic dropsies and calculous disorders; and it has been employed in the treatment of intermittents. It is said also to be an excellent anthelmintic. If taken too largely, or in excited states of the system, it is apt to occasion gastric irritation, flatulence, hemorrhoids, headach, and fever. As a medicine, it is at present more used externally than inwardly. Bruised and applied to the feet, it acts very beneficially as a revulsive in disorders of the head; and is especially useful in the febrile complaints of children, by quieting restlessness and producing sleep. Its juice mixed with oil, or the garlick itself bruised and steeped in spirits, is frequently used as a liniment in infantile convulsions, and other cases of spasmodic or nervous disorder among children. The same application has been made in cases of cutaneous eruption. A clove of garlick, or a few drops of the juice introduced into the ear, are said to prove highly efficacious in atonic deafness; and the bulb, bruised and applied in the shape of a poultice above the pubis, has sometimes restored action to the bladder in cases of retention of urine from debility of that organ. In the same shape it has been recommended as a resolvent in indolent tumours, and may perhaps prove beneficial by stimulating the absorbents.

Garlick may be taken in the form of pill; or the clove may be swallowed either whole, or cut into pieces of a convenient size. Its juice is also frequently administered mixed with sugar. The infusion in milk was at one time highly recommended, and the syrup is officinal. The dose in substance is from half a drachm to a drachm, or even two drachms of the fresh bulb. That of the juice is half a fluidrachm.

Off. Prep. Syrupus Allii, *U.S.* W.

ALLIUM CEPA. Bulbus. *Dub.*

Onion.

Ognon, *Fr.;* Zwiebel-Lauch, *Germ.;* Cipolla, *Ital.;* Cebolla, *Span.*

Allium. See ALLIUM, *U. S.*

Allium Cepa. Willd. *Sp. Plant.* ii. 80. The onion is a perennial bulbous plant, with a naked scape, swelling towards the base, exceeding the leaves in length, and terminating in a simple umbel of white flowers. The leaves are hollow, cylindrical, and pointed.

The original country of this species of Allium is unknown. The plant has been cultivated from time immemorial, and is now diffused over the whole civilized world. All parts of it have a peculiar pungent odour, but the bulb only is used.

Properties. This is of various size and shape, ovate, spherical, or flattened, composed of concentric fleshy and succulent layers, and covered with dry membranous coats, which are reddish, yellowish, or white, according to the variety. It has, in a high degree, the characteristic odour of the plant, with a sweetish and acrid taste. Fourcroy and Vauquelin obtained from it a white acrid volatile oil holding sulphur in solution, albumen, much uncrystallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, citrate of lime, and lignin. The expressed juice is susceptible of the vinous fermentation.

Medical Properties and Uses. The onion is stimulant, diuretic, expectorant, and rubefacient. Taken moderately, it increases the appetite and promotes digestion, and is much used as a condiment; but in large quantities it is apt to cause flatulence, gastric uneasiness, and febrile excitement. The juice is occasionally given, made into syrup with sugar, in infantile catarrhs and croup, in the absence of much inflammatory action. It is also recommended in dropsy and calculous disorders. Deprived of its essential oil by boiling, the onion becomes a mild esculent; and it is much more used as food than as medicine. Roasted and split, it is sometimes applied as an emollient cataplasm to suppurating tumours. W.

ALOE. *U.S.*

Aloes.

"Aloe Spicata. Extractum. *The extract.*" *U.S.*

Off. Syn. ALOES SPICATÆ EXTRACTUM. *Lond.;* ALOES EXTRACTUM. Ex variis alöes speciebus. *a.* ALOE HEPATICA. *b.* ALOE SOCOTORINA. *Ed.;* ALOE HEPATICA, ex A. vulgari. ALOE SOCOTORINA, ex A. spicatâ. *Dub.*

Suc d'aloès, *Fr.;* Aloe, *Germ., Ital.;* Aloë, *Span.;* Musebber, *Arab.*

Most of the species belonging to the genus Aloe are said to yield a bitter juice, which has all the properties of the officinal aloes. It is impossible, from the various and sometimes conflicting accounts of writers, to determine exactly from which of the species the drug is in all instances actually derived. The *Aloe spicata*, however, is generally acknowledged to be an abundant source of it; and the *Aloe vulgaris*, and *Aloe Soccotrina* of Haworth or *Aloe vera* of Miller, are usually ranked among the medicinal species. In Loudon's Encyclopædia of plants are also mentioned the *A. purpurascens* of Haworth, and the *A. aborescens** of the Hortus Kewensis; and others are, without doubt, occasionally resorted to. The U.S. Pharmacopœia and that of London at present recognise only the *Aloe spicata.* We shall confine ourselves to a description of this species, noticing others only incidentally, when speaking of the products which they afford.

ALOE. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Asphodeleæ.

Gen. Ch. *Corolla* erect, mouth spreading, bottom nectariferous. *Filaments* inserted into the receptacle. *Willd.*

Aloe spicata. Willd. *Sp. Plant.* ii. 185. This species of aloes was described by Thunberg; but we cannot ascertain that it has been figured. The stem is round, three or four feet high, about four inches in diameter, and leafy at the summit. The leaves are spreading, subverticilate, about two feet long, broad at the base, gradually narrowing to the point, channeled or grooved upon their upper surface, and with remote teeth upon their edges. The flowers are of a scarlet colour and bell-shaped, and spread horizontally in very close spikes. They contain a large quantity of purple honey juice. The spiked aloes is a native of Southern Africa, growing near the Cape of Good Hope, and, like all the other species of this genus, preferring a sandy soil. In some districts of the colony it is found in great abundance, particularly at Zwellendam, near Mossel bay, where it almost covers the surface of the country. As it grows spontaneously, and requires not the least culture, the Hottentots find an occupation accordant with their indolent habits, in collecting and preparing the juice. The process is exceedingly simple. According to Thunberg, the leaves are cut off and so arranged, that the lowest serves as a gutter to convey the juice, which runs from the wounded surface, into a suitable recipient. In other accounts, it is stated, that the juice is extracted by pressure from the leaves previously cut in pieces. The liquor is inspissated by heat in iron cauldrons, and when of a proper consistence is poured into casks which contain from one hundred to three hundred pounds.

---

* The *A. vulgaris*, *A. Soccotrina*, *A. purpurascens*, and *A. arborescens*, are considered by some botanists as mere varieties of the *A. perfoliata* of Linnæus.

Commercial History and Varieties. Three varieties of aloes reach the markets of this country; that of the Cape of Good Hope, the Socotrine, and the Hepatic.

1. The Cape Aloes, which is by far the most abundant, and by its extraordinary cheapness and excellent qualities, promises to supersede the other varieties, has been imported chiefly if not exclusively from G. Britain, as no direct trade has till recently been carried on between the U. States and the Cape of Good Hope. It has sometimes been confounded with the Socotrine from which, however, it differs very considerably in appearance and sensible properties. By the German writers it is called *shining aloes.* When freshly broken, it has a very dark olive colour approaching to black, presents a smooth bright almost glassy surface, and if held up to the light appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow colour, and being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. The odour is strong and disagreeable, but not nauseous. It has not the slightest mixture of the aromatic. Cape aloes, when perfectly hard, is very brittle, and readily reduced to powder; but in very hot weather, it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter. It is usually imported in casks or boxes.

2. Socotrine Aloes.—The genuine Socotrine aloes is produced in the Island of Socotora, which lies in the Straits of Babelmandel, about forty leagues to the east of Cape Guardafui; but we are told by Ainslie, that the greater part of what is sold under that name is prepared in the kingdom of Melinda, upon the eastern coast of Africa. It is stated by the same author, that the Island of Socotora now belongs to the princes of Hadramaut, a province of Arabia, contiguous to Yemen; and it is probable that the commerce in this variety of aloes is carried on chiefly by the maritime Arabs, who convey it either to India, or up the Red Sea by the same channel through which it reached Europe before the discovery of the southern passage into the Indian Ocean. The species of Aloe which yields it is not certainly known. Ainslie says that it is evidently from the same species with the Cape aloes; but he does not give his reasons for the opinion; and the external character of the drug is so different from that of the Cape, that we cannot but hesitate in admitting their identity of origin. We have been able to discover no good reason for depriving the *A. Soccotrina* of Haworth —the *A. vera* of Miller—of the honour formerly conceded to it, of producing this highly valued variety of aloes. The process for procuring the medicine in Socotora is said to differ somewhat from that followed at the Cape. The juice, expressed from the leaves, is allowed to stand for some time, that the feculent matter may subside; the clear liquor is then poured off into flat dishes and evaporated in the sun. When sufficiently hard, it is introduced into skins and exported. A portion ascends the Red Sea, and through Egypt reaches the ports of Smyrna and Malta, whence it is sent to London. Another portion is carried to Bombay, and thence transmitted to various parts of the world. The little that reaches this country either comes by special order from London, or is brought by our India traders. We have seen a parcel of the drug said to have been received in our market directly from the Island of Socotora.

The Socotrine aloes is in pieces of a yellowish or reddish-brown colour, wholly different from that of the former variety. It is rendered much darker by exposure to the air. Its surface is somewhat glossy, and its fracture smooth and conchoidal, with sharp and semi-transparent edges. The colour of its powder is a bright golden yellow. It has a peculiar, not unpleasant odour, and a taste, which, though bitter and disagreeable, is accompanied with an aromatic flavour. Though hard and pulverulent in cool weather, it is somewhat tenacious in summer, and softens by the heat of the hand.

Much of the aloes sold as the Socotrine, has never seen the island of Socotora, nor even the Indian seas. It has been customary to affix this title as a mark of superior value to those portions of the drug, from whatever source they may have been derived, which have been prepared with unusual care, and are supposed to be of the best quality. Thus, both in Spain and the West Indies, the juice which is obtained without expression, and inspissated in the sun without artificial heat, is called Socotrine aloes; and is probably little inferior to the genuine drug.

The Socotrine aloes has been very long known under this name, and in former times held the same superiority in the estimation of the profession, which it still, to a certain degree, retains.

3. Hepatic Aloes.—This variety is prepared in the West Indies and Spain; and is also brought from the ports of India, particularly from Bombay. According to Ainslie, it is not produced in Hindostan; but taken thither from Yemen in Arabia. It is probably obtained from the same plant or plants which yield the Socotrine; but prepared with less care than this variety, or by a different process. In Spain it is procured from the *Aloe vulgaris*. But the British West Indies are the source of by far the greater part of this variety that is consumed in Europe. In Barbadoes and Jamaica, the aloes plant is largely cultivated in the poorer soils; and in the former island especially, the drug has been so abundantly produced, that the name of Barbadoes aloes has been frequently used as synonymous with hepatic. The species most extensively cultivated in the West Indies, is the *Aloe vulgaris*,* a native of Southeastern Europe, and supposed to be the true aloe of the ancients. The *A. Soccotrina*,† *A. purpurascens*,‡ and *A. arborescens*,§ are also said to be cultivated in these islands. The process for preparing the aloes appears to be somewhat different in different places, or at least as described by different authors. The finest, which is usually called Socotrine, results from the inspissation of the juice placed in bladders or shallow vessels, and exposed to the sun. The common kind is made either by boiling the juice to a proper consistence, or by first forming a decoction of the plant, and then evaporating the decoction. In either case, when the liquor has attained the consistence of honey, it is poured into calabashes and allowed to harden.

Hepatic aloes, like the Socotrine, is of a reddish-brown colour, but is darker and less glossy. It derived its name from the supposed resemblance of its colour to that of the liver. It has none of the aromatic odour of the Socotrine, and is often exceedingly unpleasant. The taste is nauseous, and intensely bitter. The fracture is not so smooth, nor the edges so sharp and transparent as in either of the first mentioned varieties. It softens in the hand, and becomes adhesive. The powder is of a dull olive-yellow colour. Comparatively little of the hepatic aloes is used in this country.

‡ Curtis's Botanical Magazine, pl. 1474.

§ De Candolle, Plantes Grasses, fig. 38. Curtis's Botanical Magazine, pl. 1306.

The *Caballine, fetid*, or *horse aloes* seldom if ever reaches us. It is a very impure and offensive variety of the drug, procured from the dregs of the juice deposited during the preparation of the more valuable varieties. It is given only to horses; and the best Cape aloes is so cheap, as to render the importation of the caballine, for this purpose, unnecessary. It is almost black, quite opaque, hard, and in consequence of the sand and other impurities which it contains, of a rough fracture.

General Properties. The odour of aloes is different in the different varieties. The taste is in all of them intensely bitter and very tenacious. The colour and other sensible properties have already been sufficiently described. Several distinguished chemists have investigated the nature and composition of aloes. The opinion at one time entertained, that it was a gum-resin, has been abandoned since the experiments of Braconnot, who found it to consist of a bitter principle, soluble in water and in alcohol of 38° B., which he considered peculiar and named *resino-amer;* and of another substance, in much smaller proportion, inodorous and nearly tasteless, very soluble in alcohol, and scarcely soluble in boiling water, which he designated by the name of *flea-coloured principle.* These results have been essentially confirmed by the experiments of Trommsdorff, Bouillon-Lagrange, and Vogel, who consider the former substance as extractive matter, and the latter as having the chief characters of resin. Besides these principles, Trommsdorff discovered in a variety of hepatic aloes, a proportion of insoluble matter which he considered as albumen; and Bouillon-Lagrange and Vogel found that Socotrine aloes yields, by distillation, a small quantity of volatile oil, which they could not obtain from the hepatic. The proportions of the ingredients vary greatly in the different varieties of the drug; and the probability is, that scarcely any two specimens would afford precisely the same results. Braconnot found about 73 per cent. of the *bitter principle* and 26 of the *flea-coloured principle.* Trommsdorff obtained from Socotrine aloes about 75 parts of extractive, and 25 of resin; and from the hepatic 81.25 of extractive, 6.25 of resin, and 12.50 of albumen, in the hundred parts. The former variety, according to Bouillon-Lagrange and Vogel, contains 68 per cent. of extractive and 32 of resin; the latter 52 of extractive, 42 of resin, and 6 of the albuminous matter of Trommsdorff. We are not aware that any analysis has been published of the Cape aloes as a distinct variety.

Berzelius considers the resin of Trommsdorff and others, to belong to that form of matter which he calls *apothême*, (See *Extracts*,) and which is nothing more than extractive, altered by the action of the air. It may be obtained separate, by treating aloes with water, and digesting the undissolved portion with oxide of lead, which unites with the *apothême*, forming an insoluble compound, and leaves a portion of unaltered extractive, which had adhered to it, dissolved in the water. The oxide of lead may be separated by nitric acid very much diluted; and the *apothême* remains in the form of a brown powder, insoluble in cold water, very slightly soluble in boiling water to which it imparts a yellowish-brown colour, soluble in alcohol, ether, and alkaline solutions, and burning like tinder without flame and without being melted. According to the same author, the bitter extractive which constitutes the remainder of the aloes, may be obtained by treating the watery infusion of the drug with oxide of lead, to separate a portion of *apothême* which adheres to it, and evaporating the liquor. Thus procured, it is a yellowish, translucent, gum-like substance, fusible by a gentle heat, of a bitter taste, soluble in ordinary alcohol, but insoluble in that fluid when anhydrous, and in ether. Chlorine produces with its solution a precipitate analogous to *apothême.* Cold sulphuric acid dissolves without changing it. Nitric acid dissolves it, producing a greenish colour. Its solution is rendered brighter by acids, which occasion a slight precipitate, and dark red by the alkalies and the salts of iron. The acetate of lead, tartarized antimony, permuriate of tin, and the salts of manganese, zinc, and copper, do not disturb the solution; the protomuriate of tin, and the nitrates of mercury and silver occasion precipitates.

Aloes yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the resinous portion or *apothême* of Berzelius is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by converting the extractive into insoluble *apothême.* The alkalies, their carbonates, and soap, alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odour of the drug.

Those substances only are incompatible with aloes, which alter or precipitate the bitter extractive; as the insoluble portion is without action upon the system. Its aqueous solution keeps a long time, even for several months, without exhibiting mouldiness or putrescency; but it becomes ropy, and acquires the character, which it did not previously possess, of affording an abundant precipitate with the infusion of galls.

Medical Properties and Uses. Aloes was known to the ancients. It is mentioned in the works of Dioscorides and Celsus, the former of whom speaks of two kinds. The varieties are similar in their mode of action. They are all cathartic, operating very slowly but certainly, and having a peculiar affinity for the large intestines. Their action, moreover, appears to be directed rather to the muscular coat than to the exhalent vessels; and the discharges which they produce, are therefore seldom very thin or watery. In a full dose they quicken the circulation, and produce general warmth. When frequently repeated, they are apt to irritate the rectum, giving rise, in some instances, to hemorrhoids, and aggravating them when already existing. Aloes has also a decided tendency to the uterine system. Its emmenagogue effect, which is often very considerable, is generally attributed to a sympathetic extension of irritation from the rectum to the uterus; but we can see no reason why the medicine should not act specifically upon this organ; and its influence in promoting menstruation is by no means confined to cases in which its action upon the neighbouring intestine is most conspicuous. A peculiarity in the action of this cathartic is, that an increase of the quantity administered beyond the medium dose, is not attended by a corresponding increase of effect. Its tendency to irritate the rectum may be obviated, in some measure, by combining it with soap or an alkaline carbonate; but it does not follow, as supposed by some, that this modification of its operation is the result of increased solubility; for aloes given in a liquid state produces the same effect as when taken in pill or powder, except that it acts somewhat more speedily. Besides, when externally applied to a blistered surface, it operates exactly in the same manner as when internally administered; thus proving that its peculiarities are not dependent upon the particular form in which it may be given, but on specific tendencies to particular parts.* With its other powers, aloes combines the property of slightly stimulating the stomach. It is therefore, in minute doses, an excellent remedy in habitual costiveness, attended with torpor of the digestive organs. From its special direction to the rectum, it has been found peculiarly useful in the treatment of ascarides. In amenorrhœa it is perhaps more frequently employed than any other remedy, entering into almost all the numerous empirical preparations which are habitually resorted to by females in this complaint, and enjoying a no less favourable reputation in regular practice. It is, moreover, frequently given in combination with more irritating cathartics, in order to regulate their liability to excessive action. Aloes is contra-indicated by the existence of hemorrhoids, and is obviously unsuitable, unless modified by combination, to the treatment of inflammatory diseases.

---

* See a paper on Endermic Medication, by Dr. Gerhard, in the North Am. Med. and Surg. Journ. vol. x. p. 155.

The medium dose is 10 grains; but as a laxative it will often operate in the quantity of 2 or 3 grains, and when a decided impression is required, the dose may be augmented to 20 grains. In consequence of its excessively bitter and somewhat nauseous taste, it is most conveniently administered in the shape of pill.*

ALTHÆÆ FOLIA et RADIX. *Lond.*

Leaves and Root of Marshmallow.

"Althæa officinalis. *Folia et Radix.*" *Lond.*

Off. Syn. ALTHÆÆ OFFICINALIS RADIX. *Ed.;* ALTHÆA OFFICINALIS. Folia et Radix. *Dub.*

Guimauve, *Fr.;* Eibisch, *Germ.;* Altea, *Ital.;* Altea, Malvavisco, *Span.*

ALTHÆA. *Sex. Syst.* Monadelphia Polyandria.—*Nat. Ord.* Malvaceæ.

Gen. Ch. *Calyx* double, the exterior six or nine-cleft. *Capsules* numerous, one-seeded. *Willd.*

Althæa Officinalis. Willd. *Sp. Plant*, iii. 770.; Woodv. *Med. Bot.* p. 552. t. 198. The marshmallow is an herbaceous perennial, with a perpendicular branching root, and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are alternate, petiolate, nearly cordate on the lower part of the stem, oblong-ovate and obscurely three-lobed above, somewhat angular, irregularly serrate, pointed, and covered on both sides with a soft down. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The corolla has five spreading, obcordate petals, of a pale purplish colour. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant grows throughout Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country on the borders of salt marshes. In some parts of the Continent of Europe, it is largely cultivated for medical use. The whole plant abounds in mucilage. Both the leaves and root are officinal, but the latter only is employed to any extent in this country. The flowers are sometimes to be found in the shops, but are scarcely used.

---

* Dr. Paris enumerates the following empirical preparations, containing aloes as a leading ingredient:—ANDERSON'S PILLS, consisting of aloes, jalap, and oil of anniseed; HOOPER'S PILLS, of aloes, myrrh, sulphate of iron, canella, and ivory black; DIXON'S ANTIBILIOUS PILLS, of aloes, scammony, rhubarb, and tartarized antimony; SPEEDIMAN'S PILLS, of aloes, myrrh, rhubarb, extract of chamomile, and ess. oil of chamom.; DINNER PILLS, of aloes, mastich, red roses, and syrup of wormwood; FOTHERGILL'S PILLS, of aloes, scammony, colocynth, and oxide of antimony; PETER'S PILLS, of aloes, jalap, scammony, gamboge, and calomel; and RADCLIFF'S ELIXIR, of aloes, cinnamon, zedoary, rhubarb, cochineal, syrup of buckthorn, and spirit and water as the solvent; to which may be added, LEE'S WINDHAM PILLS, consisting of gamboge, aloes, soap, and nitrate of potassa, and LEE'S NEW-LONDON PILLS, of aloes, scammony, gamboge, calomel, jalap, soap, and syrup of buckthorn.

The roots should be collected in autumn from plants at least two years old. They are cylindrical, branched, as thick as the finger or thicker, from a foot to a foot and a half long, externally of a yellowish colour which becomes grayish by drying, within white and fleshy. They are usually prepared for the market by removing the epidermis. Our shops are supplied chiefly if not exclusively from Europe.

Properties. Marshmallow root comes to us in pieces three or four inches or more in length, usually not so thick as the finger, generally round but sometimes split, white externally and downy from the mode in which the epidermis is removed, light and easily broken with a short somewhat fibrous fracture, of a peculiar faint smell, and a mild mucilaginous sweetish taste. Those pieces are to be preferred which are plump and but slightly fibrous. The root contains a large proportion of mucilage besides starch and saccharine matter, and yields its virtues readily to boiling water. A principle was discovered in it by M. Bacon, which he supposed to be peculiar to the Marshmallow, but which has been ascertained to be identical with the *asparagin* of Robiquet. MM. Boutron-Charlard and Pelouze have found it to belong to that class of organic principles, which are convertible by the agency of strong acids, of potassa or soda, or even of water alone at a high temperature, into ammonia and peculiar acids, and which are designated by the termination *amide.* Thus asparagin, which must now be called *asparamide,* is converted into ammonia and *asparmic,* or, as it was formerly named, *aspartic acid;* and one atom of the resulting asparmate of ammonia is equivalent to one atom of asparamide, and one of water. A solution of asparamide undergoes this change, in some degree, even at common temperatures; but the alteration is greatly promoted by the agency of heat, or of the alkalies. Acids, also, produce the same effect, but they unite with the ammonia and liberate the asparmic acid. Asparamide may be obtained by macerating the bruised marshmallow root in four times its weight of cold water for two days, decanting, repeating the maceration with a fresh portion of water, uniting the infusions thus prepared, evaporating to one-half, filtering, again evaporating to the consistence of syrup, and allowing the liquor to stand. In four or five days crystals of asparamide are deposited. This principle is crystallizable, inodorous, of a very feeble taste, soluble in 58 parts of cold water, and in much less boiling water, more soluble in diluted alcohol than in water, but insoluble in anhydrous alcohol and ether. It is found in various other plants besides the marshmallow, as in the shoots of asparagus, in all the varieties of the potato, and in the roots of the comfrey and liquorice plant. (*Journ. de Pharm.* xix. 208.) Marshmallow root is said to become somewhat acid by decoction.

Those pieces should be rejected which are woody, discoloured, mouldy, of a sour or musty smell, or a sourish taste.

The roots of other *Malvaceæ* are sometimes substituted without disadvantage, as they possess similar properties;—such are those of the *Althæa rosea* or *hollyhock*, and the *Malva Alcea.*

Medical Properties and Uses. The virtues of the marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. The roots themselves, boiled and bruised, are sometimes employed as a poultice. The leaves are applied to similar uses. In France, the powdered root is much used in the preparation of pills and electuaries.

ALUMEN. *U.S., Lond., Ed., Dub.*

Alum.

Alun, *Fr., Dan., Swed.;* Alaun, *Germ.;* Allume, *Ital.;* Alumbre, *Span.*

The officinal alum is a double salt, consisting of the sulphate of alumina, united to the sulphate of potassa. It is included in the Materia Medica of the United States and British Pharmacopœias, as an article to be procured from the wholesale manufacturer.

Alum is manufactured occasionally from earths which contain it ready formed, but most generally from minerals which, embracing most or all of its constituents, are hence called alum ores. The principal alum ores are the alum stone, a native mixture of subsulphate of alumina and sulphate of potassa, which is found in large quantities at Tolfa and Piombino in Italy, and certain natural mixtures of sulphuret of iron with schist or clay.

It is particularly at the Solfaterra and other places in the kingdom of Naples, that alum is extracted from earths which contain it ready formed. The ground being of volcanic origin, and having a temperature of about 104°, an efflorescence of pure alum is formed upon its surface. This is collected and lixiviated, and the solution made to crystallize by slow evaporation in leaden vessels sunk in the ground.

The alum stone is manufactured into alum by calcination, and subsequent exposure to the air for three months, the mineral being frequently sprinkled with water, in order that it may be brought to the state of a soft mass. This is lixiviated, and the solution obtained crystallized by evaporation. The alum stone may be considered as consisting of alum united with a certain quantity of the hydrate of alumina. This latter, by the calcination, loses its water, and becomes incapable of remaining united with the alum of the mineral, which is consequently set free. Alum of the greatest purity is obtained from this ore.

Native mixtures of sulphuret of iron and schist, when compact, are treated by exposure to the air for a month. The mineral is then stratified with wood, which is set on fire. The combustion which ensues is slow and protracted; the sulphur is in part converted into sulphuric acid, which unites with the alumina; and the sulphate of alumina thus formed generates a portion of alum with the potassa derived from the ashes of the wood. The iron, in the mean time, is almost wholly converted into peroxide, and thus becomes insoluble. The matter is lixiviated, and the solution crystallized into alum by evaporation. The mother-waters, containing sulphate of alumina, are then drawn off and made to yield a fresh portion of alum by the addition of sulphate of potassa. This process is practised at Liege in France.

When the alum ore consists principally of sulphuret of iron and clay, sulphate of iron or green vitriol is obtained at the same time. The ore is placed in heaps, and occasionally sprinkled with water. The sulphuret of iron gradually absorbs oxygen and passes into the state of sulphate, which effloresces on the surface of the heap. Part of the sulphuric acid formed unites with the alumina; so that after the chemical changes are completed, the heap contains both the sulphate of iron and the sulphate of alumina. At the end of about a year, the matter is lixiviated, and the solution of the two sulphates obtained is concentrated to the proper degree in leaden boilers. The sulphate of iron crystallizes, while the sulphate of alumina, being a deliquescent salt, remains in the mother-waters. These are drawn off, and treated with a certain quantity of the sulphate of potassa in powder, heat being at the same time applied. They are then allowed to cool, that the alum may crystallize. The crystals are then separated from the solution, and purified by a second solution and crystallization. They are next added to boiling water to full saturation, and the solution is transferred to a cask, where, on cooling, nearly the whole concretes into a crystalline mass. The cask is then taken to pieces, and the salt having been broken up, is packed in barrels for the purposes of commerce. This process is most generally followed for manufacturing alum, being employed in France, Great Britain, and the United States.

Alum is manufactured also by the direct combination of its constituents. With this view, clays are selected as free from iron and carbonate of lime as possible, and calcined to peroxidize the iron and render them more easily pulverizable; after which they are dissolved, by the assistance of heat, in weak sulphuric acid. The sulphate of alumina thus generated, is next crystallized into alum by the addition of sulphate of potassa in the usual manner.

Alum has not been an article of import into the United States to any extent since 1818, or a year or two earlier; the demand since then having been almost entirely supplied by the domestic manufacture. The aggregate quantity made may be estimated at from a thousand to twelve hundred tons. The method usually employed in the United States, consists in the direct combination of sulphuric acid with clay. Tyson & Ellicott, however, manufacturing chemists of Baltimore, employ for making alum the ore found at Cape Sable, on the Magothy river, Maryland. This ore, which was extensively worked during the late war under the superintendence of Dr. Troost, consists of lignite, clay, sulphuret of iron, and sand. It exists in beds of from six to ten feet in thickness, covered by a stratum of sand. It is dug up, and thrown into heaps of from one to three thousand tons, is set on fire, and continues to burn for several years. The ashes are transported to the manufactory, where they are lixiviated, and the solution obtained evaporated in leaden vessels. When the solution indicates about 25° of Baumé's hydrometer, sulphate of potassa is added, after which it is drawn off to crystallize. At the end of about a week, the crystallization having been completed, the mother-waters are pumped off; and the crystals, after being washed and well drained, are dissolved in leaden boilers. From these the solution is transferred to the refining vessels, and left for about three weeks to crystallize. At the end of that time, the mother-waters are drawn off from the crystals, and these are broken up, dried, and packed in barrels.

Besides the officinal alum, the mode of manufacturing which is above described, there are several varieties of this salt, in which the potassa is replaced by other bases, as for example, ammonia and soda. *Ammoniacal alum*, or the sulphate of alumina and ammonia, is sometimes manufactured in France, where it is formed by adding putrid urine to a solution of the sulphate of alumina. It resembles so exactly the potassa alum, that it is impossible by simple inspection to distinguish them; and in composition, it is perfectly analogous to the ordinary alum. It may, however, be distinguished by subjecting it to a strong calcination, after which alumina will be found as the sole residue; or by rubbing it up with potassa or lime and a little water, when the smell of ammonia will be perceived.

Properties. Alum is a white, slightly efflorescent salt, crystallized in regular octohedrons, and possessing a sweetish, astringent taste. It dissolves in between fourteen and fifteen times its weight of cold, and three-fourths of its weight of boiling water. Its sp. gr. is 1.71. It reddens litmus, but changes the blue tinctures of the petals of plants, green. It cannot therefore be properly said to contain an excess of acid. When heated a little above the boiling point, it undergoes the aqueous fusion; and if the heat be continued, it loses its water, swells up, becomes white and opaque, and is converted into the officinal preparation called *dried alum.* (See *Alumen Exsiccatum.*) Exposed to a red heat, it gives off oxygen, together with sulphurous and anhydrous sulphuric acids; and the residue consists of alumina and sulphate of potassa. When calcined with finely divided charcoal, it gives rise to a peculiar spontaneously inflammable substance, called *pyrophorus*, which consists of a mixture of sulphuret of potassium, alumina, and charcoal.

Several varieties of alum are known in commerce. *Roche* alum, so called from its having come originally from Roccha in Syria, is a purer sort of alum, which occurs in fragments about the size of an almond, and covered with an efflorescence of a pale rose colour. A similar description is given by Thenard of the *Roman* alum, which he states to be in small fragments, having a rose coloured surface, arising from a slight covering of oxide of iron.

All the alums of commerce contain more or less sulphate of iron, varying from five to seven parts in the thousand. Roman alum is among the purest varieties, and is, therefore, much esteemed The iron is readily detected by adding to a solution of the suspected alum a few drops of the ferrocyanate of potassa, which will cause a greenish-blue tint, if iron be present. The quantity of iron usually present, though small, is injurious to the alum when used in dyeing. It may, however, be purified by dissolving it in the smallest quantity of boiling water, and stirring the solution as it cools; or by repeated solutions and crystallizations.

Incompatibles. Alum is incompatible with the alkalies and their carbonates, lime and lime-water, magnesia and its carbonate, tartrate of potassa, and acetate of lead.

Composition. Alum was for a long time regarded as a sulphate of alumina. It is to Descroizilles, Vauquelin, and Chaptal, that we owe the discovery that it also contains sulphate of potassa, sulphate of ammonia, or both these salts. When its second base is potassa, it consists of one equivalent of tersulphate of alumina 171.7, one equiv. of sulphate of potassa 87.25, and twenty-four equiv. of water 216 = 474.95. In the ammoniacal alum, the equiv. of sulphate of potassa is replaced by one of sulphate of ammonia. In other respects its composition is the same. *Alumina* is classed by the chemist as an earth, and is essential to the constitution of alum, as it cannot be replaced by any other base. It may be obtained by precipitating a solution of alum by water of ammonia, added in excess. As thus obtained, it presents a gelatinous form, and is in the state of hydrate. In this form, it has been used by some practitioners on the continent of

Europe in diarrhœa. It consists of two equiv. of a metallic radical called *aluminium* 27.4, and three equiv. of oxygen 24=51.4. It is, therefore, a sesquioxide.

Medical Properties, &c. Alum is a powerful astringent, and as such is used both internally and externally in restraining hemorrhages. It has been recommended in free doses by Dr. Scudamore, in the form of saturated solution, in hæmoptysis and hæmatemesis. It is employed locally in the form of astringent and repellent injections and collyria. The dose in hemorrhages is from five to twenty grains, repeated every hour or two, until the bleeding abates. In less urgent cases, smaller doses are advisable; as large ones are apt to nauseate, an effect which may often be obviated by the addition of some aromatic. Dr. Percival extolled its use as a remedy in colica pictonum, in which disease it may be supposed to act on chemical principles, by converting the poisonous carbonate of lead into the inert sulphate. It may be given in these cases in doses of fifteen grains, repeated every third, fourth, or fifth hour.

In various anginose affections, it is found highly useful, topically applied either in powder or solution. When the affection is attended with membranous exudation, its efficacy has been particularly insisted on by Bretonneau, applied in solution prepared with vinegar and honey for adults, and in powder, by *insufflation*, in the cases of children. When used in the latter way, a drachm of finely powdered alum may be placed in one end of a tube, and then blown by means of the breath into the throat of the child. M. Velpeau, in 1835, extended the observations of M. Bretonneau, and has successfully applied alum, not only in simple inflammatory sore-throat, but in those forms of angina dependent on small-pox, scarlatina, &c. In these cases the powdered alum may be applied several times a day to the fauces by means of the index finger, so as to cover the affected surfaces. In the interval, the patient should gargle the throat with a solution of from two to four scruples of alum in four fluidounces of barley-water sweetened with honey. (*N. Amer. Archives of Med. and Surg. Sci.*, ii. 281.)

Alum is sometimes exhibited in the form of *alum whey*, made by boiling two drachms of alum in a pint of milk, and straining the decoction, of which two fluidrachms are a dose. Briskly agitated with the white of eggs, it forms a coagulum which is used as an external application in some forms of ophthalmia. (See *Cataplasma Aluminis.*)

* * *

AMMONIACUM. *U.S.*, *Lond.*, *Ed.*

Ammoniac.

"Heracleum gummiferum. Succus concretus. *The concrete juice.*" *U.S.*

Off. Syn. AMMONIACUM GUMMI. HERACLEUM GUMMIFERUM. Gummi Resina. *Dub.*

Gomme Ammoniaque, *Fr.;* Ammoniak, *Germ.;* Gomma Ammoniaco, *Ital.;* Goma Amoniaco, *Span.;* Ushek, *Arab.;* Semugh belshereen, *Persian.*

Much uncertainty has existed among botanists as to the plant which yields ammoniac. It was generally believed to be a species of *Ferula*, till Willdenow raised from some seeds mixed with the gum-resin found in the shops, a plant which he ascertained to be an *Heracleum*, and named *H. gummiferum*, under the impression that it must be the true source of the medicine. On this authority, the plant has been adopted by the British Colleges, and is recognised in our national Pharmacopœia. Willdenow expressly acknowledges that he could not procure from it any gum-resin, but ascribes the result to the influence of the climate. The *Heracleum*, however, does not correspond exactly with the representations given of the ammoniac plant by travellers; and Sprengel has ascertained that it is a native of the Pyrenees, and never produces gum. By this botanist it is named *H. Pyrenaicum*, though before described by Lapeyrouse under the title of *H. amplifolium*. (*Merat and De Lens.*) Mr. Jackson, in his account of Morocco, imperfectly describes a plant indigenous in that country, supposed to be a species of *Ferula*, from which gum-ammoniac is procured by the natives: but it may be doubted whether its product is the true ammoniac of the shops, which is derived exclusively from Persia. M. Fontaniér, who was sent by the French Government into the Levant, and resided many years in Persia, saw the ammoniac plant growing in the province of Fars, and transmitted a drawing of it with specimens to Paris. From these it was inferred to be a species of Ferula; and Merat and De Lens propose for it the name originally applied to it by Lemery, of *F. ammonifera*. It would appear, however, from recent accounts, that specimens of the plant obtained in Persia by Colonel Wright, and examined by Mr. David Don, prove it to belong to a genus allied to Ferula, but essentially different; and named by Mr. Don, *Dorema*. A description of it is contained in the 16th volume of the Linnean Transactions, under the name of *D. Ammoniacum*.

The ammoniac plant grows spontaneously in Farsistan, Irauk, and other Persian provinces; in the southern districts of Arabia; and perhaps in the North of Africa. It attains the height of six or seven feet, and in the spring and early part of summer abounds in a milky juice, which flows out upon the slightest puncture. From the accounts of travellers it appears, that in the month of May, the plant is pierced in innumerable places by an insect of the beetle kind. The juice, exuding through the punctures, concretes upon the stem, and when quite dry is collected by the natives. M. Fontaniér states that the juice exudes spontaneously, and that the harvest is about the middle of June. The gum-resin is sent to Bushire, whence it is transmitted to India. It reaches this country usually by the route of Calcutta. The name *gum ammoniac* is thought to have been derived from the temple of Jupiter Ammon in the Lybian desert, where the drug is said to have been formerly collected.

Properties. Ammoniac comes either in the state of separate tears, or in aggregate masses, and in both forms is frequently mixed with impurities. That of the tears, however, is preferable, as the purest may be conveniently picked out, and kept for use. These are of an irregular shape, usually more or less globular, opaque, yellowish on the outside, whitish within, compact, homogeneous, brittle when cold, and breaking with a conchoidal shining fracture. The masses are of a darker colour and less uniform structure, appearing, when broken, as if composed of numerous white or whitish tears, embedded in a dirty gray or brownish substance, and frequently mingled with foreign matters, such as seeds, fragments of vegetables, and sand, or other earth.

The smell of ammoniac is peculiar, and stronger in the mass than in the tears. The taste is slightly sweetish, bitter, and somewhat acrid. The sp. gr. is 1.207. When heated, the gum-resin softens and becomes adhesive, but does not melt. It burns with a white flame, swelling up, and emitting a smoke of a strong, resinous, slightly alliaceous odour. It is partly soluble in water, alcohol, ether, vinegar, and alkaline solutions. Triturated with water, it forms an opaque milky emulsion, which becomes clear upon standing. The alcoholic solution is transparent, but is rendered milky by the addition of water. Bucholz obtained from 100 parts of ammoniac, 22.4 parts of gum, 72.0 of resin, 1.6 of bassorin, and 4.0 of water including volatile oil and loss. Braconnot obtained 18.4 per cent. of gum, 70.0 of resin, 4.4 of a gluten-like substance (bassorin,) and 6.0 of water, with 1.2 per cent. of loss. Hagen succeeded in procuring the volatile oil in a separate state by repeated distillation with water. It has a penetrating disagreeable odour, and a taste at first mild, but afterwards bitter and nauseous. The resin of ammoniac is dissolved by alcohol and the fixed and volatile oils, but is divided by ether into two resins, of which one is soluble, the other insoluble in that menstruum.

Medical Properties and Uses. This gum-resin is stimulant and expectorant, in large doses cathartic, and, like many other stimulants, may be so given as occasionally to prove diaphoretic, diuretic, or emmenagogue. It has been employed in medicine from the highest antiquity, being mentioned in the writings of Hippocrates. The complaints in which it is most frequently used, are chronic catarrh, asthma, and other pectoral affections, attended with deficient expectoration without acute inflammation, or with too copious secretion from the bronchial mucous membrane dependent upon debility of the vessels. It is thought to have been useful in some cases of amenorrhœa, and in those chlorotic and hysterical conditions of the system arising out of this complaint. It has also been prescribed in obstructions or chronic engorgements of the abdominal viscera, under the vague notion of its deobstruent power. Any good which it may do in these affections, is more probably ascribable to its revulsive action upon the alimentary mucous membrane. Authors speak of its utility in long and obstinate colics dependent on mucous matter lodged in the intestines; but it would be difficult to ascertain in what cases such mucous matter existed, and, even allowing its presence, to decide whether it was a cause or a result of the diseased action. Ammoniac is usually administered in combination with other expectorants, with tonics, or emmenagogues. It is much less used than formerly. Externally applied in the shape of a plaster, it is thought to be useful as a discutient or resolvent in white swellings of the joints and other indolent tumours. (See *Emplastrum Ammoniaci.*)

It is given in substance, in the shape of pill or emulsion. The latter form is preferable. (See *Mistura Ammoniaci.*) The dose is from ten to thirty grains.

AMMONIÆ MURIAS. *U.S.*, *Lond.*, *Dub.*

Muriate of Ammonia.

Off. Syn. MURIAS AMMONIÆ. *Ed.*

Sal ammoniac, Hydrochlorate of ammonia; Sel ammoniac, *Fr.;* Salmiak, *Germ.:* Sale ammoniaco, *Ital.;* Sal ammoniaco, *Span.*

This salt is placed in the Materia Medica list of all the Pharmacopœias noticed in this work, as a substance to be obtained from the wholesale manufacturer. It originally came from Egypt, where it was obtained by sublimation from the soot of camels' dung, which is used in that country for fuel. Since the year 1790, it has been manufactured in Europe by chemical processes, and the importation from Egypt has gradually ceased. The first European sal ammoniac manufactories were established in England and Scotland. Soon after these, one was set up in Paris by Baumé, and shortly afterwards another in Brunswick in Germany.

Preparation. The French method of preparing muriate of ammonia is as follows. Bones and old woollen rags are distilled in cast iron cylinders, placed over furnaces. At one end of the cylinder, which is made to open and shut, the substances are introduced, and from the other, by means of a tube communicating with a series of casks connected together by other tubes, the products are disengaged. A tube from the last cask carries the incondensible products either outside the manufactory, or into the furnace to be destroyed by combustion. In case of the latter arrangement, partitions of wire-gauze must be placed at intervals within the tube, to prevent explosions. The products consist of water, oil, a small quantity of acetate and hydrocyanate of ammonia, and a large quantity of carbonate of ammonia. After being withdrawn from the casks, they are mixed with powdered sulphate of lime, or made to filter through a layer of this salt. By double decomposition, sulphate of ammonia and carbonate of lime are generated, the former of which remains in solution, while the latter is precipitated. Chloride of sodium (common salt) is now added in excess to the solution of the sulphate; and by a new play of affinities, implying the decomposition of water, muriate of ammonia and sulphate of soda are formed. The solution of the mixed salts is then concentrated, and by successive evaporations and coolings, they are made to crystallize separately. The muriate of ammonia is then dried, and finally sublimed. The drying is performed by exposing the crystallized salt to heat in a kind of oven, whereby it becomes changed into a spongy friable ash-coloured mass. This is put, while hot, into glazed earthen jars, furnished with a perforated cover, where it is sublimed by means of a sand-bath, at a heat of 320°.

The process pursued in England is in principle the same as that adopted by the French. In London, however, much use is made of the ammoniacal liquor, generated in coal-gas works, to obtain the sulphate of ammonia for sublimation with the common salt.

Besides the method just described, there are several others for obtaining sulphate of ammonia, for the purpose of being converted into muriate of ammonia. Sometimes bones are heated to redness directly with sulphate of lime or gypsum. In this case there are formed sulphate of ammonia and carbonate of lime, the former of which is separated by lixiviation. In Scotland, the sulphate of ammonia is procured by lixiviating the soot of sulphureous coal.

It has been proposed to obtain muriate of ammonia by heating a mixture of the bittern of sea-salt works with animal matters. The bittern consists principally of muriate of magnesia, and the animal matters furnish impure carbonate of ammonia; and these salts, by double decomposition, generate muriate of ammonia and carbonate of magnesia. Other processes have been proposed or practised, for an account of which the reader is referred to the Chemical Essays of Mr. Parkes, who has appropriated a separate essay to this subject.

Commercial History. All the muriate of ammonia consumed in the United States, is obtained from abroad. Its commercial varieties are known under the names of the *crude* and *refined.* The crude is imported from Calcutta in chests, containing from 350 to 400 pounds. This variety is consumed almost entirely by coppersmiths and other artisans in brass and copper, being employed for the purpose of keeping the metallic surfaces bright preparatory to brazing. The refined comes to us exclusively from England, packed in casks containing from 5 to 10 cwt.

Properties. Muriate of ammonia is a white salt, occurring either in circular concavo-convex cakes of about two inches in thickness, or crystallized in conical masses. It has a sharp saline taste, but no smell. Its sp. gr. is 1.45. It dissolves in three times its weight of cold, and about its own weight of boiling water; and during its solution, considerable cold is produced. A hot concentrated solution, when it cools, deposites the salt in feathery crystals. These when exposed to heat, first undergo the watery fusion, then dry, and finally, below a red heat, sublime in the form of white vapours. The muriate of ammonia possesses the property of combining with the corrosive chloride of mercury and increasing its solubility. It is decomposed by the strong mineral acids, and by the alkalies and alkaline earths, the former disengaging muriatic acid, and the latter ammonia. It is a permanent salt in the ordinary states of the atmosphere, but sometimes the conical crystallized variety is deliquescent, owing to the presence of a portion of muriate of lime. Hence the sublimed salt is always to be preferred in medicine. It is incompatible with acetate of lead and nitrate of silver, producing with these salts a precipitate of chloride either of lead or silver.

Composition. Muriate of ammonia is composed of one equivalent of muriatic acid 36.42, and one equiv. of ammonia 17.15 = 53.57; or in ultimate constituents, of one equiv. of chlorine, one equiv. of nitrogen, and four equiv. of hydrogen. In equivalent volumes, it consists of two volumes of muriatic acid, and two volumes of ammonia, condensed into a solid.

Medical Properties. Muriate of ammonia is employed both internally and externally. Internally it acts primarily on the alimentary canal as a peculiar irritative stimulus; but secondarily as an excitant and alterative of the capillary, glandular, and lymphatic system, as also of the mucous, serous and fibrous membranes, the secretions of which it is supposed to improve. It has accordingly been deemed useful in catarrhal and rheumatic fevers, pneumonia, bronchitis, pulmonary catarrh, and other mucous and serous inflammations, after their first violence has abated. Several cases of pectoral disease, simulating incipient phthisis, are reported to have been cured by this remedy in Otto's Bibliothek, for 1834. (*N. Amer. Archives*, i. 299, *Jan.* 1835.) It has also been found useful in visceral obstructions of various kinds. The dose is from five to thirty grains, repeated every two or three hours, given in powder mixed with powdered gum or sugar, or dissolved in syrup or mucilage. It is very little used as an internal remedy in the United States; but on the continent of Europe, especially in Germany, it is a good deal employed. Considering the potent nature of its constituents, and the various testimony borne in favour of its powers, its employment has perhaps been too much neglected.

Externally applied, it operates in two ways,—by the cold produced during its solution, and by the stimulus created by the salt itself. It acts in the former way when it proves beneficial in the form of lotions, applied to the head in mania, apoplexy, and violent headachs; and on the latter principle, in the cure of indolent tumours, contusions, gangrene, psora, ophthalmia, chilblains, &c. For external use, it may be dissolved to the extent of an ounce in nine fluidounces of water, a fluidounce of alcohol being added to the solution.

Muriate of ammonia is used in the preparation of several officinal compounds, but does not enter into the composition of any of them except the *Ferrum Ammoniatum*, and *Hydrargyrum Ammoniatum*. B.

Amygdalus communis. Willd. *Sp. Plant.* ii. 982; Woodv. *Med. Bot.* p. 507. t. 183. The almond tree rises usually from fifteen to twenty feet in height, and divides into numerous spreading branches. The leaves stand upon short footstalks, are about three inches long, and three quarters of an inch broad, elliptical, pointed at both ends, veined, minutely serrated, with the lower serratures and petioles glandular, and are of a bright green colour. The flowers are large, of a pale red colour varying to white, with very short peduncles and petals longer than the calyx, and are usually placed in numerous pairs upon the branches. The fruit is of the peach kind, with the outer covering thin, tough, dry, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, which contains the kernel or almond.

There are several varieties of this species of Amygdalus, differing chiefly in the size and shape of the fruit, the thickness of the shell, and the taste of the kernel. The last is the most important point of difference, and has given rise to the botanical division of the species into—1. *Amygdalus* (*communis*) *dulcis*, and 2. *Amygdalus* (*communis*) *amara*, the former bearing sweet, the latter bitter almonds. It is the fruit of the first only which is considered officinal in the Pharmacopœia of the United States.

The almond tree is a native of Persia, Syria, and Barbary; and is very extensively cultivated in various parts of the South of Europe. It has been introduced into the United States; but in the northern and middle sections the fruit does not usually come to perfection. We are supplied with sweet almonds chiefly from Spain and the South of France. They are distinguished into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. Dr. A. T. Thomson states, that the *Jordan* almonds, which are taken from Malaga to England, and are the best imported into that country, are said to be the produce of a distinct species of Amygdalus. According to the same author, the bitter almonds are obtained from Morocco.

Properties. The shape and appearance of almonds are too well known to require description. Each kernel consists of two white cotyledons, enclosed in a thin, yellowish-brown, bitter skin, which is easily separable after immersion in boiling water. When deprived of this covering, they are called *blanched almonds.* The two varieties of sweet and bitter almonds deserve each a separate notice, as they are both considered officinal in several of the Pharmacopœias of Europe, and both are occasionally employed in medicine.

1. Amygdalæ Dulces. *Sweet Almonds.* These when blanched are without smell, and have a sweet, very pleasant taste, which has rendered them a favourite article of diet in almost all countries where they are readily attainable. They are, however, generally considered of difficult digestion. By the analysis of M. Boullay, it appears that they contain in 100 parts, 5 parts of pellicle, 54 of fixed oil, 24 of albumen, 6 of uncrystallizable sugar, 3 of gum, 4 of fibrous matter, 3.5 of water, and 0.5 of acetic acid comprising loss. The fixed oil, which may be obtained by expression, is colourless or slightly tinged with yellow, sweet and bland to the taste, and may be substituted for olive oil in most of the economical uses to which the latter is applied. (See *Oleum Amygdalæ.*) Almonds when rubbed with water form a milky emulsion, the insoluble matters being suspended by the agency of the mucilaginous and saccharine principles.

2. Amygdalæ Amaræ. *Bitter Almonds.* These are smaller than the preceding variety. They have the bitter taste of the peach-kernel, and, though in their natural state inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They have generally been supposed to contain, in addition to the principles found in the other variety, a portion of hydrocyanic acid, and an essential oil, to which their peculiar taste and smell, and their peculiar operation upon the system, have been ascribed. The bitter almonds yield their fixed oil by pressure; and the essential oil, impregnated with hydrocyanic acid, may be obtained from the residue by distillation with water. This oil, usually called *oil of bitter almonds,* has a bitter, acrid, burning taste, and the peculiar odour of the kernel in a very high degree. It is of a yellowish colour, heavier than water, soluble in alcohol and ether, slightly soluble in water, and deposites, upon standing, a white crystalline substance, which consists chiefly of benzoic acid. It may be entirely freed from hydrocyanic acid by agitating it strongly with hydrate of lime and a solution of muriate of iron, and submitting the mixture to distillation. The oil comes over with the water, from which it may be separated in the usual manner. Thus purified, it still retains its peculiar odour, with a burning and aromatic taste; but, as proved by Dr. Göppert of Breslau, is wholly destitute of those poisonous properties which distinguish the oil in its original state, and which depend on the presence of hydrocyanic acid. The odour of the oil of bitter almonds has been usually, but erroneously, ascribed to this acid, which, on examination, will be found to smell very differently. The same remark is applicable to the essential oils of the cherry laurel, of the bird cherry, and probably of other vegetables supposed to contain hydrocyanic acid. The benzoic acid which the oil of bitter almonds deposites upon standing, has been satisfactorily proved by Robiquet and Boutron not to pre-exist in the oil, but to result from the absorption of oxygen. It appears also, from their experiments, that the oil itself does not exist already formed in the bitter almond, and that water is essential to its production. The principle from which it is probably formed, and upon which the peculiar sensible, and perhaps medicinal properties of the bitter almond depend, is a crystallizable, azotized substance, white, inodorous, of a sweetish bitter taste, unalterable in the air, soluble in alcohol, exhaling an agreeable odour when heated alone, and an odour of ammonia when heated

with a solution of caustic potassa. MM. Robiquet and Boutron, by whom it was discovered, have conferred on it the name of *amygdalin*. (*Journ. de Chim. Méd.* vi. 380 and 750.)

The essential oil of bitter almonds operates upon the system in a manner closely analogous to that of hydrocyanic acid. A single drop is sufficient to destroy a bird, and four drops have occasioned the death of a dog of the middle size. The distilled water of bitter almonds operates in a similar manner, though less powerfully; and the almonds themselves have proved deleterious when taken in considerable quantities. Confectioners employ bitter almonds for communicating flavour to the syrup of orgeat. The kernel of the peach possesses similar properties, and is frequently used as a substitute. The oil of bitter almonds is much used by the perfumers.

Medical Properties and Uses. Sweet almonds exercise no other influence upon the system than that of a demulcent. The emulsion formed by triturating them with water is a pleasant vehicle for the administration of other medicines, and is itself useful in cases of catarrhal affection. Bitter almonds are more energetic, and, though not much in use, might undoubtedly be employed with advantage in cases to which the hydrocyanic acid is applicable. An emulsion made with them has been beneficially prescribed in pectoral affections attended with cough, and is said to have cured intermittents when bark has failed. (*Bergius, Mat. Med.*) It probably operates by diminishing the excitability of the nervous system, and moderating existing irritation. Dr. A. T. Thomson says that he has found it extremely useful as a lotion in acne rosea and in impetigo. Bitter almonds are said by Hufeland to have been successfully employed for the expulsion of the tape worm. In some persons they produce urticaria when taken in the smallest quantities.

The *oil of bitter almonds* might probably be substituted with advantage for the medicinal hydrocyanic acid, as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, if the oil is preserved in well stopped bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22.5 parts of Prussian blue. From this fact it may be inferred, that the oil is about four times as strong as our officinal hydrocyanic acid, and may therefore be given in the dose of a quarter of a drop to be gradually and very cautiously increased till some effect upon the system is observed. It may be administered in emulsion with gum Arabic, loaf sugar, and water.

AMYGDALUS PERSICA. Folia. *Dub.*

Peach Leaves.

Pecher, *Fr.*; Pfirsichbaum, *Germ*; Persico, *Ital.*; Alberchigo, *Span.*

Amygdalus. See AMYGDALA.

Amygdalus Persica. Willd. *Sp. Plant.* ii. 982; Woodv. *Med. Bot.* p. 511. t. 184.—*Persica Vulgaris.* Miller, Lamarck. Every one is familiar with the appearance of the common peach tree. It is characterized specifically by having "all the serratures of the leaves acute, and by its sessile solitary flowers." Though its native country is not certainly known, it is generally supposed to have been brought originally from Persia. In no country, perhaps, does it attain greater perfection, as regards the character of its fruit, than in the United States.

Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juice susceptible of the vinous fermentation; and a distilled liquor prepared from them is much used in some parts of the country under the name of peach brandy.

The kernels of the fruit bear a close resemblance in appearance and properties, and probably in chemical nature, to the bitter almonds, for which they are frequently, and without inconvenience, substituted in our shops. They are employed by distillers in the preparation of *liqueurs*, and by cake-bakers to give flavour to various productions of their ovens.

The flowers and leaves also have the peculiar odour and taste of the bitter almonds, and probably contain hydrocyanic acid. The leaves afford a volatile oil by distillation. These are the only part directed by the Dublin College.

Medical Properties, &c. Peach leaves are said to be laxative; and they probably exert, to a moderate extent, a sedative influence over the nervous system. They have been used as an anthelmintic with great reported success. More recently their infusion has been recommended in morbid irritability of the bladder. Half an ounce of the dried leaves may be infused in a pint of boiling water, and half a fluidounce given for a dose three times a day.

The flowers also are laxative; and a syrup prepared from them is considerably used, in infantile cases, upon the continent of Europe. Woodville states that a drachm of the dried flowers, or half an ounce in their recent state, given in infusion, is the dose as a vermifuge.

The kernels have more of the peculiar powers of hydrocyanic acid, and therefore require to be used with some caution. Blanched, and rubbed up with hot water, they form an emulsion well adapted to coughs depending on or associated with nervous irritation.

The dried fruit stewed with sugar is an excellent laxative article of diet, suitable to cases of convalescence attended with torpid bowels. W.

AMYLUM. *Lond., Ed.*

Starch.

"Triticum hybernum. *Amylum.*" *Lond.*

Amidon, *Fr.;* Stärkmehl, *Germ.;* Amido, *Ital.;* Almidon, *Span.*

Starch is a proximate vegetable principle contained in most plants, and especially abundant in the various grains, such as wheat, rye, barley, oats, rice, maize, &c.; in other seeds, as peas, beans, chestnuts, acorns, &c.; and in numerous tuberous roots, as those of the potato, (*Solanum tuberosum,*) the sweet potato, (*Convolvulus Batatus,*) the arrow-root, the cassava plant, and different species of Curcuma. The process for obtaining it consists essentially in reducing the substances in which it exists to a state of minute division, agitating or washing them with cold water, straining or pouring off the liquid, and allowing it to stand till the fine fecula which it holds in suspension has subsided. This, when dried, is starch, more or less pure according to the care taken in conducting the process. The starch of commerce is procured chiefly from wheat, sometimes also from potatoes. Our space will not allow us to enter into details in relation to the particular steps of the operation to which these substances are subjected; and the omission is of less consequence, as starch is never prepared by the apothecary.

Starch is white, pulverulent, opaque, and as found in the shops, is usually in columnar masses, having a somewhat crystalline aspect, and producing a peculiar sound when pressed between the fingers. It is insoluble in alcohol, ether, and cold water; but unites with boiling water, which, on cooling, forms with it a soft semi-transparent paste, or a gelatinous opaline solution, according to the proportion of starch employed. The paste, placed on folds of blotting paper, renewed as they become wet, abandons its water, contracts, and assumes the appearance of horn. If the proportion of starch be very small, the solution after slowly depositing a very minute quantity of insoluble matter, continues permanent, and upon being evaporated yields a semi-transparent mass, which is partially soluble in cold water. The starch has, therefore, been modified by the combined agency of water and heat; nor can it be restored to its original condition. Exposed, in the dry state, to a temperature somewhat above 212°, it undergoes, according to Caventou, a similar modification; and a degree of heat sufficient to roast it slightly converts it into a substance soluble in cold water, and applicable to the same purposes as gum in the arts. The same change in regard to solubility is, to a certain extent, produced by mechanical means, as by trituration in a mortar; and that the effect is not the result of heat evolved by friction, is evinced by the fact that it takes place when the starch is triturated with water. The soluble substance which results from the action of heat, was supposed by Caventou to be identical with that produced during the fermentation of starch, upon which De Saussure had previously conferred the name of *amidine;* but new opinions upon the subject are now entertained by chemists, in conformity with the views originally presented by Raspail, and subsequently confirmed and extended by Guibourt, Guérin, and others. According to these views, starch consists of organized granules, which, examined by the microscope appear to be of various form and size. These granules consist of a thin exterior pellicle or tegument, and of an interior substance, the former wholly insoluble, the latter soluble in water. The former constitutes, according to M. Payen, only 4 or 5 thousandths of the weight of starch, according to M. Guérin, who, however, did not obtain it entirely pure, as much as 2.2 per cent. In relation to the interior portion different opinions are entertained. M. Guérin thinks that it consists of two distinct substances, one soluble in cold water, which he calls *amidine*, the other soluble at first in boiling water but becoming insoluble by evaporation, which he distinguishes by the name of *soluble amidin*, while upon the substance of which the teguments consist, he confers the name of *tegumentary amidin.* Thus, when one part of starch is boiled for fifteen minutes in one hundred parts of water, and the liquid is allowed to stand, a small portion, consisting of the broken teguments, is gradually deposited. If the solution be now filtered and evaporated, another portion is deposited which cannot afterwards be dissolved. This is the *soluble amidin.* When wholly deprived of this portion and evaporated to dryness, the solution yields the part soluble in cold water, or the *amidine.* According to MM. Payen and Persoz, the interior portion of the globules consists only of a single substance, which is converted into the two just mentioned by the agency of water; and Thenard is inclined to the same opinion. Starch, in its perfect state, is not affected by cold water, because the exterior insoluble tegument prevents the access of the liquid to the interior portion; but when the pellicle is broken by the agency of heat, or by mechanical means, the fluid is admitted, and the starch partially dissolved.

Iodine forms with starch, whether in its original state or in solution, a blue compound; and the tincture of iodine is the most delicate test of its presence in any mixture. The colour varies somewhat according to the proportions employed. When the two substances are about equal, the compound is of a beautiful indigo blue; if the iodine is in excess, it is blackish-blue; if the starch, violet blue. A singular property of the iodide of starch is that its solution becomes colourless if heated, and afterwards recovers its blue colour upon cooling. Alkalies unite with starch, forming soluble compounds, which are decomposed by the acids, the starch being precipitated. It is thrown down from its solution by lime water and baryta water, forming insoluble compounds with these earths. The solution of subacetate of lead precipitates it in combination with the oxide of the metal. It is dissolved by the diluted acids, which, by long boiling, convert it first into *dextrine*,* and ultimately into a saccharine substance similar to the sugar of grapes. This result is perhaps most readily obtained by means of sulphuric acid. A similar conversion into dextrine and the sugar of grapes is effected by means of a principle called *diastase*, recently discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, after germination. (See *Hordeum.*) Strong muriatic and nitric acids dissolve it; and the latter, by the aid of heat, converts it into oxalic and malic acids. Concentrated sulphuric acid decomposes it. Mixed with hot water and exposed to a temperature of about 70°, it undergoes fermentation, which results in the formation of several distinct principles, among which are sugar, a gummy substance (perhaps *dextrine*), and a modification of starch which De Saussure called *amidine.*

Starch may be made to unite with tannin by boiling their solutions together; and a compound results, which, though retained by the water while hot, is deposited when it cools. Hence the precipitate which takes place in the decoction of Peruvian bark, in which both these principles are contained.

Starch, as obtained from different substances, is somewhat different in its characters. That from wheat, when examined by a microscope, is found to consist of smaller globules than that from the potato. It is usually, moreover, harder and more adhesive, owing, according to Guibourt, to the escape of a portion of the interior substance of the granules in the act of grinding the grain. This attracts some moisture from the air, and thus becoming glutinous, acts as a bond between the unbroken globules. The fecula from the root of the *Maranta arundinacea*, commonly called *arrow-root*, is in grains much larger and more shining than those of wheat starch, and quite transparent when examined by the microscope. Hence the powder in mass is of a less brilliant whiteness. The granules are intermediate in size between those of the fecula of wheat and those of the potato starch. In the last they are largest. In other respects these three forms of starch are closely similar. *Tapioca* differs in being partially soluble in cold water, as well as in its consistence. (See *Tapioca.*) This is attributable to the circumstance that it is granulated upon heated plates of iron, which cause many of the granules to burst. A form of fecula is procured from the same root, which bears a close resemblance to arrow-root, differing only in the smaller size of its granules, and their greater uniformity, as evinced by examination by the microscope. This fecula is prepared by drying in the open air, without the assistance of heat. It is called *moussache* in France. *Sago* differs from the ordinary forms of starch, rather in the degree of its aggregation than in any essential quality. It is scarcely at all soluble in cold water; and the microscope shows that it consists of small unbroken granules like those of the potato, closely pressed and often matted together. If prepared with heat, the degree of it must have been insufficient to produce much change in the integrity of the organized granules.

---

* *Dextrine* is a substance resembling gum in appearance and properties, but differing from it in not affording mucic acid by the action of nitric acid. It is largely dissolved by water, hot or cold, and forms a mucilaginous solution, from which it is precipitated by alcohol. This fluid has no action on dextrine.

Starch consists, according to Berzelius, of 6.674 parts of hydrogen, 44.250 of carbon, and 49.076 of oxygen in the hundred. The results obtained by Gay-Lussac and Thenard are nearly the same.

Medical Properties, &c. Starch is nutritive and demulcent, but in its ordinary form is seldom administered internally. Powdered and dusted upon the skin, it is sometimes used to absorb irritating secretions, and prevent excoriation. Dissolved in hot water and allowed to cool, it is often employed in enemata, either as a vehicle of other substances, or as a demulcent application in irritated states of the rectum.

AMYRIDIS GILEADENSIS RESINA. *Ed.*

Balsam of Gilead.

Baume de la Mecque, *Fr.;* Mekkabalsam, *Germ.;* Balsamo della Mecca, *Ital.;* Opobalsamo, Balsamo de Meca, *Span.*

The genuine Balsam of Gilead is the resinous juice of the *Amyris Gileadensis* of Linn., the *Balsamodendron Gileadense* of Kunth, a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and still retains its value in the estimation of the eastern nations, among whom it is employed both as a medicine and cosmetic. In western Europe, and in this country, it is never found in a state of purity, and its use has been entirely abandoned. We notice it here, simply because it is retained by the Edinburgh College. It possesses no medical properties which do not exist in other balsamic or terebinthinate juices.

It was formerly known by the name of *opobalsamum*, while the dried twigs of the tree were called *xylobalsamum*, and the dried fruit, *carpobalsamum.* W.

◆

ANCHUSÆ TINCTORIÆ RADIX. *Ed.*

Alkanet Root.

Orcanette, *Fr.;* Alkanne, *Germ.;* Alcanna, *Ital.;* Bugula, *Span.*

Anchusa. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Boragineæ.

Gen. Ch. *Corolla* funnel-shaped; the throat closed with arches. *Seeds* sculptured at the base. *Willd.*

Anchusa tinctoria. Willd. *Sp. Plant.* i. 758; Woodv. *Med. Bot.* p. 314. t. 106. The *dyer's alkanet* has a perennial root, with round, rough, hairy, branching, lax, herbaceous stems, from six inches to a foot or more in height, and furnished with long, lanceolate, obtuse, hairy, sessile leaves. The flowers are reddish-purple, and disposed in terminal bracteate spikes, with bractes longer than the calyx, which is five-parted. The arches are enclosed beneath the anthers in the tube of the corolla.

This species of Anchusa is a native of the Grecian Archipelago and the South of Europe. It is said in some medical works to be cultivated abundantly in the South of France; but the plant referred to is probably the *Lithospermum tinctorium* of Linnæus and De Candolle, the *Anchusa tinctoria* of Lamarck, which is a native of that country, and the root of which is considered as the true alkanet by the French writers.

Alkanet, as found in the shops, is in pieces three or four inches in length, from the thickness of a quill to that of the little finger, somewhat twisted, consisting of a dark-red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the centre, and composed of numerous distinct, slender, cohering fibres. As it comes to us it is usually much decayed internally, very light, and of a loose almost spongy texture. The fresh root has a faint odour and a bitterish astringent taste; but when dried it is nearly inodorous and insipid. Its colouring principle, which abounds most in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a fine deep red; but is insoluble in water. It may be obtained separate by first exhausting the root with water, and then treating it with a weak solution of the carbonate of potassa or soda, from which the colouring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses decided acid properties, uniting with the alkalies and earths to form neutral compounds, which are of a blue colour, and have the singular property of being soluble in alcohol and ether. He calls it *anchusic acid*, and states that it is capable of being sublimed unchanged. (*Journ. de Pharm.* xix. 105.) The tincture of alkanet has its colour deepened by the acids, changed to blue by the alkalies, and again restored by neutralizing the latter substances. It may, therefore, be used as a test. The extract obtained by evaporating the tincture is dark brown.

Medical Properties and Uses. Alkanet root is somewhat astringent, and was formerly applied to the treatment of several diseases; but it is now employed exclusively for colouring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. It is said also to be used in the preparation of spurious Port wine. W.

ANETHI SEMINA. *Lond.*

Dill Seeds.

"Anethum graveolens. *Semina.*" *Lond.*

Aneth a odeur forte, *Fr.;* Dill, *Germ.;* Aneto, *Ital.;* Eneldo, *Span.*

Anethum. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Fruit* nearly ovate, compressed, striated. *Petals* involuted, entire. *Willd.*

Anethum graveolens. Willd. *Sp. Plant.* i. 1469; Woodv. *Med. Bot.* p. 125. t. 48. Dill is an annual plant, three or four feet high, with a long spindleshaped root; an erect, striated, jointed, branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks, and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Spain, Portugal, and the South of France. It is cultivated in all the countries of Europe, and has been introduced into our own gardens; but is much less esteemed than its congener, the *A. Fœniculum.* The seeds only are used. They are usually rather more than a line in length, of an oval shape, thin, concave on one side, convex and striated on the other, of a brown colour, and surrounded by a yellowish membranous expansion. Their smell is strong and aromatic, but less agreeable than that of fennel-seed; their taste moderately warm and pungent. These properties depend on a volatile oil, which may be obtained separate by distillation. It is of a pale yellow colour, and of the sp. gr. 0.881. The bruised seeds impart their virtues to alcohol and to boiling water.

Medical Properties. Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion. The dose is from fifteen grains to a drachm.

ANGELICA. *U.S. Secondary.*

Angelica.

"Angelica atropurpurea. Planta. *The plant.*" *U.S.*

Angelica. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferae.

Gen. Ch. *Fruit* elliptic, compressed, somewhat solid and corticate, ridges three, dorsal acute, intervals grooved, margin alated. *General involucre* none. (*Sprengel.*) *Umbel* large, many-rayed, spreading; *umbellet* dense, subhemispheric; *involucell* about eight-leaved. *Calyx* five-toothed. *Petals* inflected. *Nutall.*

Angelica atropurpurea. Willd. *Sp. Plant.* i. 1430. This indigenous species of Angelica, sometimes called *masterwort*, has a perennial purplish root, and a smooth herbaceous stem, the dark colour of which has given rise to the trivial name of the plant. The leaves are ternate, and supported by very large inflated petioles. The partitions of the leaf are nearly quinate, with ovate, acute, deeply serrate, somewhat lobed leaflets, of which the three terminal are confluent. The flowers are greenish-white.

The purple angelica extends throughout the United States from Canada to Carolina, growing in meadows and marshy woods, and flowering in June and July. It is smaller than the *A. Archangelica*, with a less succulent stem. The whole plant is officinal. It has a strong odour, and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acrimony is dissipated by drying.

Medical Properties, &c. The medical virtues of the plant are similar to those of the garden Angelica of Europe, for which it has been proposed as a substitute. It is, however, little employed. An infusion is occasionally used in flatulent colic; and we are told that the stems are sometimes candied by the country people. W.

ANGELICA ARCHANGELICA. Semina. *Dub.*

ANGELICÆ ARCHANGELICÆ RADIX. *Ed.*

The Seeds and Root of Garden Angelica.

Angelique, *Fr.;* Engelwurzel, *Germ.;* Arcangelica, *Ital.;* Angelica, *Span.*

ANGELICA. See ANGELICA. *U.S.*

Angelica Archangelica. Willd. *Sp. Plant.* i. 1428; Woodv. *Med. Bot.* p. 86. t. 35. The *garden angelica* has a long, thick, fleshy, biennial root, furnished with many fibres, and sending up annually a hollow, jointed, round, channeled, smooth, purplish stem, which rises five feet or more in height, and divides into numerous branches. The leaves, which stand upon round fistulous footstalks, are very large, doubly pinnate, with ovate lanceolate, pointed, acutely serrate leaflets, of which the terminal one is three-lobed. The flowers are small, greenish-white, and disposed in very large, many-rayed, terminal umbels, composed of numerous dense, hemispherical umbellets.

This plant is a native of the north of Europe, and is found in the high, mountainous regions in the southern section of that continent, as in Switzerland and among the Pyrennees. It has become an object of culture in various parts of Europe, and may be occasionally met with in the gardens of this country. It flowers during the summer. The whole plant diffuses a fragrant odour, and possesses aromatic properties; but the root and seeds only are officinal.

1. *The root* should be dug up in the autumn of the first year, as it is then less liable to become mouldy and worm-eaten than when taken from the ground in the spring. It is spindle-shaped, an inch or more in thickness at its upper extremity, and beset with numerous long descending radicles. The fresh root has a yellowish-gray epidermis, a fleshy yellow parenchyma, and when wounded yields a honey-coloured juice, which has all the aromatic properties of the plant. The dried root is grayish-brown and much wrinkled externally, whitish and spongy within, breaking with a starchy fracture, exhibiting shining resinous points. It is very apt to be attacked by worms. The smell is strong and fragant, the taste at first sweetish, afterwards warm, aromatic, bitterish, and somewhat musky. These properties are extracted by alcohol, and less perfectly by water. The constituents of the root, according to John, are an essential oil, gum, inulin, bitter extractive, an acrid resin, lignin, and a peculiar principle soluble only in a solution of potassa. Five hundred parts yielded by distillation nearly four parts of volatile oil.

2. *The seeds* are two or three lines long, oval, obtuse or somewhat notched at the ends, flat, and marked with a longitudinal furrow on one side, convex with three angular ridges on the other. They are ash-coloured, and have the same smell and taste as the root. M. Fée says that they keep well.

Medical Properties. Angelica is an elegant aromatic tonic; but is little employed in the United States. The Laplanders, in whose country it flourishes, are said to esteem it highly as a condiment and medicine. In Europe, the stems are frequently made into a preserve, and used in desserts in order to excite the stomach. The dose of the root or seed in substance is from thirty grains to a drachm.

ANGUSTURA. *U.S.*

Angustura Bark.

"Galipea Officinalis. *Hancock.* Bonplandia trifoliata. *Plant. Equinoct.* Cortex. *The Bark.*" *U.S.*

Off. Syn. CUSPARIÆ CORTEX. Cusparia febrifuga. Cortex. *Lond.;* BONPLANDIÆ TRIFOLIATÆ CORTEX. Angustura. *Ed.;* ANGUSTURA. BONPLANDIA TRIFOLIATA. Cortex. *Dub.*

Angusture, *Fr.;* Angusturarinde, *Germ.;* Corteçcia dell' Angustura, *Ital.;* Corteza de Angostura, *Span.*

The subject of Angustura bark, in its botanical relations, has been involved in some confusion. The drug was at first supposed to be derived from a species of Magnolia, and in Europe was referred by some to the *Magnolia glauca* of this country. Humboldt and Bonpland were the first to enlighten the medical public as to its true source; though the name which it bore was sufficient to indicate the neighbourhood of its growth. These gentlemen, when at Angustura, a South American city upon the banks of the Orinoco, received specimens of the foliage of the plant from which the bark was obtained; and afterwards believed that they had found this same plant in a tree growing in the vicinity of Cumana. This latter they had the opportunity of personally inspecting, and were therefore enabled to describe accurately. Unable to attach it to any known genus, they erected it into a new one, with the title of *Cusparia*, a name of Indian origin, to which they added the specific appellation of *febrifuga.* On the authority of these botanists, the *Cusparia febrifuga* was generally believed to be the true source of the medicine, and was recognised as such by the London College. A specimen having in the mean time been sent by them to Willdenow, the name of *Bonplandia* was imposed on the new genus by that celebrated botanist; and was subsequently adopted by Humboldt and Bonpland themselves, in their great work on equinoctial plants. Hence the title of *Bonplandia trifoliata*, by which the tree is described in many works on materia medica. De Candolle, however, having found in the description all the characters of the genus *Galipea* of Aublet, has rejected both these titles, and proposes to substitute that of *Galipea Cusparia.* After all these commutations, however, it appears from the researches of Dr. Hancock, who resided for several months in the country of the Angustura bark tree, that the plant described by Humboldt and Bonpland is not that which yields the medicine, but probably another species of the same genus, which these authors had mistaken for it, having been led into error by the imperfect specimens which they received.* Among other striking differences in the two plants, is that of their size; the tree described by Humboldt and Bonpland being of great magnitude, attaining the height of sixty or eighty feet, while that from which the bark is obtained is never higher than twenty feet. Hancock proposes for the latter the title of *Galipea officinalis*, which has been adopted in the Pharmacopœia of the United States.

GALIPEA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Diosmeæ.

---

* See a paper by John Hancock, M. D., in the Transactions of the London Medico-Botanical Society.

ria. De Cand. *Prodrom.* i. 730. This is a small tree, irregularly branched, rising to the medium height of twelve or fifteen feet, with an erect stem from three to five inches in diameter, and covered with a smooth gray bark. The leaves are alternate, petiolate, and composed of three leaflets, which are oblong, pointed at each extremity, from six to ten inches in length, from two to four in breadth, and supported upon the common petiole by short leafstalks. They are very smooth and glossy, of a vivid green colour, marked occasionally with small whitish round spots, and when fresh, of a strong odour resembling that of tobacco. The flowers are numerous, white, arranged in axillary and terminal, peduncled racemes, and exhale a peculiar unpleasant odour. The fruit consists of five bivalve capsules, of which two or three are commonly abortive. The seeds, two of which are contained in each capsule, one often abortive, are round, black, and of the size of a pea.

This tree grows in great abundance on the mountains of Carony, situated between the 7th and 8th degrees of N. latitude; and is well known in the missions of Tumeremo, Uri, Alta Gracia, and Cupapui, near the Orinoco, upwards of two hundred miles from the ocean. It flourishes at the height of from six hundred to one thousand feet above the level of the sea. Its elegant white blossoms, which appear in vast profusion in August and September, add greatly to the beauty of the scenery.

The bark is generally brought from the West India ports packed in casks; but, according to Mr. Brande, the original package, formed in Angustura or its neighbourhood, consists of the leaves of a species of palm, surrounded by a network made of sticks.

Properties. The pieces are of various lengths, for the most part slightly curved, rarely quilled, sometimes nearly flat, from half a line to a line or more in thickness, pared away towards the edges, covered externally with a light yellowish-gray or whitish wrinkled epidermis, and internally of a yellowish-fawn colour. They are very fragile, breaking with a short resinous fracture, and yield, on being pulverized, a pale yellow powder; but when macerated for a short time in water, they become soft and tenacious, and may be cut into strips with scissors. The smell of Angustura bark is peculiar and disagreeable when fresh, but becomes fainter with age; the taste is bitter and slightly aromatic, leaving a sense of pungency at the end of the tongue. According to Fischer, it contains volatile oil, bitter extractive, a hard and bitter resin, a soft resin, a substance analogous to caoutchouc, gum, lignin, and various salts. The active principles are probably the volatile oil and bitter extractive. The bark imparts its virtues to water and alcohol.

Dr. A. T. Thomson states that precipitates are produced with the infusion by the solutions of sulphate of iron, tartrate of antimony and potassa, sulphate of copper, acetate and subacetate of lead, bichloride of mercury, nitrate of silver, and pure potassa; by nitric and sulphuric acids; and by the infusions of galls and yellow cinchona; but how far these substances are medicinally incompatible with the bark, it would be difficult in the present state of our knowledge to determine.

False Angustura. Under this title, the European writers on materia medica describe a bark which has been introduced on the continent mixed with the true Angustura bark, and, possessing poisonous properties, has in some instances produced unpleasant effects when prescribed by mistake for that medicine. It is distinguished by its greater thickness, hardness, weight, and compactness; by its dull and brownish fracture; by the appearance of its epidermis, which is sometimes covered with a ferruginous efflorescence, sometimes is yellowish-gray, and marked with prominent white spots; by the brownish colour and smoothness of its internal surface; by the white slightly yellow powder which it yields; by its total want of odour, and its intense tenacious bitterness. When steeped in water it does not become soft like the true Angustura. Analyzed by Pelletier and Caventou, it was found to contain a peculiar alkaline principle which they called *brucia*, and upon which its poisonous operation depends. Of this alkali we shall have occasion to speak in another place. (See *Nux Vomica.*) In consequence of its presence, a drop of nitric acid upon the internal surface of the bark produces a deep blood-red spot. The same acid applied to the external surface renders it emerald green. In the true Angustura bark, a dull red colour is produced by the acid on both surfaces. The *false Angustura* was at first supposed to be derived from the *Brucea antidysenterica;* but as this tree is a native of Africa, the opinion was abandoned when it was considered that the bark in question was brought from South America. Botanists now generally refer it to an unknown species of Strychnos; and the correctness of this reference is rendered probable by the fact, that the *nux vomica*, and *bean of St. Ignatius*, both products of species of Strychnos, have been found to contain *brucia.*

Medical Properties and Uses. Angustura bark had been long used by the natives of the country where it grows, before it became known in Europe. From the continent its employment extended to the West Indies, where it acquired considerable reputation. It was first taken to Europe about fifty years since, and attracted particular attention among the English physicians. It is now ranked among the officinal remedies throughout Europe and America; but has not sustained the estimation in which it was at first held; and in the United States is not much prescribed. Its operation is that of a stimulant tonic. In large doses it also evacuates the stomach and bowels, and is often employed for this purpose in South America. It was at one time considerably used as a febrifuge in the place of Peruvian bark; but has not been found generally successful in the intermittents of northern latitudes. It is said to be particularly efficacious in bilious diarrhœas and dysenteries; and has been recommended in dyspepsia, and other diseases in which a tonic treatment is demanded. The testimony, however, of practitioners in Europe and the United States, is not strongly in its favour; and it is probably better adapted to tropical diseases, than to those of temperate climates. Hancock employed it very extensively in the malignant bilious intermittent fevers, dysenteries, and dropsies of Angustura and Demarara; and speaks in the strongest terms of its efficacy in these complaints. The form in which he used it was that of fermented infusion, as recommended by the native practitioners. It has this advantage over Peruvian bark, that it is less apt to oppress the stomach.

It may be given in powder, infusion, tincture, or extract. The dose in substance is from ten to thirty grains. In larger quantities it is apt to produce nausea. From five to fifteen grains is the dose of the extract, which, however, according to Dr. Hancock, is inferior to the powder or infusion. To obviate nausea, it is frequently combined with aromatics.

PIMPINELLA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. Fruit ovate-oblong. *Petals* inferior. *Stigma* nearly globular. *Willd.*

Pimpinella Anisum. Willd. *Sp. Plant.* i. 1473; Woodv. *Med. Bot.* p. 135. t. 52. This is an annual plant, about a foot in height, with an erect, slightly scabrous, striated, and branching stem. The leaves are petiolate, the lower roundish-cordate, entire or irregularly three-lobed, the upper three-parted or ternate. The flowers are white, and in terminal compound umbels, destitute of involucres.

Anise is a native of Egypt and the Levant, but has been introduced into the South of Europe, and is cultivated in various parts of that continent. It is also cultivated occasionally in the gardens of this country. The seeds are abundantly produced in Malta and Spain. The Spanish are smaller than the German or French, and are usually preferred.

Anise seeds are about a line in length, oval, striated, somewhat downy, attached to their footstalks, and of a greenish-brown colour, with a shade of yellow. Their odour is fragrant and increased by friction; their taste warm, sweet, and aromatic. These properties, which depend on a peculiar volatile oil, are imparted sparingly to boiling water, freely to alcohol. The volatile oil exists in the envelope of the seeds, and is obtained separate by distillation. (See *Oleum Anisi.*) Their internal substance contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the two. The seeds are sometimes adulterated with small fragments of argillaceous earth; and their aromatic qualities are occasionally impaired, in consequence of a slight fermentation which they are apt to undergo in the mass, when collected before maturity.

The *Star aniseed*, the *badiane* of the French writers, though analogous in sensible properties to the common aniseed, is derived from a different plant, being the fruit of the *Illicium anisatum*, an evergreen tree growing in China, Japan, and Tartary. The fruit consists of from five to ten brownish ligneous capsules, four or five lines long, united together in the form of a star, each containing a brown shining seed. It is much used in France to flavour liquors, and the volatile oil upon which its aromatic properties depend is imported into this country from the East Indies, and sold as common oil of aniseed, to which, however, it is much superior. *Togno and Durand.*

Medical Properties and Uses. Anise is a grateful aromatic carminative; and like several other seeds of a similar character, is supposed to have the property of increasing the secretion of milk. In Europe it is much employed in flatulent colic, and as a corrigent of griping or unpleasant medicines; but in this country fennel-seed is usually preferred. Anise may be given bruised, or in powder, in the dose of twenty or thirty grains or more. The infusion is less efficient. The volatile oil may be substituted for the seeds in substance. Much use is made of this aromatic for imparting flavour to liquors.

ANTHEMIS. *U.S.*

Chamomile.

"Anthemis nobilis. Flores. *The Flowers.*" *U.S.*

Off. Syn. ANTHEMIDIS FLORES. Anthemis nobilis. Flores Simplices. *Lond.;* ANTHEMIDIS NOBILIS FLORES, *Ed.;* CHAMÆMELUM. ANTHEMIS NOBILIS. Flores. *Dub.*

Camomille Romaine, *Fr.;* Römische Kamille, *Germ.;* Camomilla Romana, *Ital.;* Manzanilla Romana, *Span.*

ANTHMIS. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. Receptacle chaffy. *Seed down* none or a membranaceous margin. *Calyx* hemispherical, nearly equal. *Florets of the ray* more than five. *Willd.*

Several species of Anthemis have been employed in medicine. The *A. nobilis*, which is the subject of the present article, is by far the most important. The *A. Cotula* or May-weed is also recognised by the U.S. Pharmacopœia. (See *Cotula.*) The *A. Pyrethrum*, which affords the pellitory root, is ranked among the officinal plants by the Dublin College. (See *Pyrethrum.*) The *A. arvensis*, a native of this country and of Europe, bears flowers which have an acrid bitter taste, and possess medical properties analogous though much inferior to those of the common chamomile, for which they are said to be sometimes substituted in Germany. They may be distinguished by their want of smell. The *A. tinctoria* is occasionally employed as a tonic and vermifuge in Europe, and is admitted among the officinal medicines by the French Codex.

Anthemis nobilis. Willd. *Sp. Plant.* iii. 2180; Woodv. *Med. Bot.* p. 47. t. 19. This is an herbaceous plant with a perennial root. The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upwards at their extremities. The leaves are bipinnate; the leaflets small, thread-like, somewhat pubescent, acute, and generally divided into three segments. The flowers are solitary, with a yellow convex disc, and white rays. The calyx is common to all the florets, of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like *paleæ.* The florets of the ray are numerous, narrow, and terminated with three small teeth. The whole herb has a peculiar fragrant odour, and a bitter aromatic taste. The flowers only are officinal.

This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes. In France, Germany, and Italy, it is generally known by the name of Roman chamomile. The flowers become double by cultivation, and in this state are usually preferred; though, as the sensible properties are found in the greatest degree in the disc, which is not fully developed in the double flowers, the single are the most powerful, and are exclusively directed by the London College. It is rather, however, in aromatic flavour, than in bitterness, that the radial florets are surpassed by those of the disc. If not well and quickly dried, the flowers lose their beautiful white colour, and are less efficient as a medicine. Those which are whitest should be preferred.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed.* The medicine, as found in our shops, consists chiefly of the double flowers, and is imported from Germany and England. From the former country are also occasionally imported, under the name of chamomile, the flowers of the *Matricaria Chamomilla*, a plant belonging to the same family with the Anthemis, and closely allied to it in sensible as well as medicinal properties. The flowers of the Matricaria are, however, less pleasant to the smell, and are considerably weaker than the true chamomile. As they reach us they are also much smaller, and differ, moreover, in exhibiting a much larger proportion of the disc florets, compared with those of the ray. They are much used in Germany.

Properties. Chamomile flowers, as usually found in the shops, are large, almost spherical, of a dull-white colour, a fragrant odour, and a warmish, bitter, aromatic taste. When fresh, their smell is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamæmelum;* and it is somewhat singular that the Spanish name *manzanilla* has a similar signification.† The flowers impart their odour and taste to both water and alcohol, the former of which, at the boiling temperature, extracts nearly one-fourth of their weight. They have not been accurately analyzed, but are known to contain a volatile oil, a bitter extractive matter, resin, and a small quantity of tannin. The first two are probably their active ingredients. (See *Oleum Anthemidis.*)

Medical Properties and Uses. Chamomile is a mild tonic, in small doses acceptable and corroborant to the stomach, in larger quantities capable of acting as an emetic. In cold infusion it is often advantageously used in cases of enfeebled digestion, whether occurring as an original affection, or consequent upon some acute disease. It is especially applicable to that condition of general debility, with languid appetite, which often attends convalescence from idiopathic fevers. As a febrifuge it has also acquired much reputation, being frequently prescribed in remittents, when the subsidence of action between the paroxysms is so considerable as to demand the use of tonics, but is not sufficiently complete to admit of a resort to Peruvian bark or its preparations. Chamomile in substance has, in some instances, proved effectual in the treatment of intermittents; but we have so many other remedies more efficient in these cases, that it is now seldom if ever employed. The tepid infusion is very often given to promote the operation of emetic medicines, or to assist the stomach in relieving itself when oppressed by its contents. The flowers are sometimes applied externally as fomentations in cases of irritation or inflammation of the abdominal viscera, and as gentle incitants in flabby, ill-conditioned ulcers. The dose of the powder as a tonic is from half a drachm to a drachm three or four times a day, or more frequently, according to the end proposed. The infusion is usually preferred. The decoction and extract cannot exert the full influence of the medicine, as the volatile oil, upon which its virtues partly depend, is driven off at the boiling temperature.

---

* Eaton tells us, in his Manual of Botany, that he has seen it growing wild near Pittsfield, Massachusetts; and Nuttal states that it is naturalized near Lewistown in Delaware.

ANTIMONIUM.

Antimony.

Regulus of antimony; Stibium, *Lat.;* Antimoine, *Fr.;* Antimon, Spiessglas, *Germ.;* Antimonio, *Span.; Ital.*

Antimony, in the metallic state, is not officinal in the British or United States Pharmacopœias; but as it enters into the composition of a number of important pharmaceutical agents and medicines, we have thought it proper to notice it under a distinct head.

Antimony exists in nature in four states; 1. As metallic antimony; 2. As an oxide; 3. As a sulphuret; and 4. As a sulphuretted oxide. It is found principally in France and Germany.

Extraction. Nearly all the antimony of commerce is extracted from the native sulphuret, which is by far the most abundant ore of this metal. The ore is first separated from its gangue by fusion. It is then reduced to powder, and placed on the floor of a reverberatory furnace, where it is subjected to a gentle heat, being constantly stirred about with an iron rake. The heat should not be sufficient to cause fusion. This process of roasting takes a good deal of time, and is known to be completed, when the matter is reduced to the state of a dull grayish-white powder. By this treatment the antimony is oxidized, and nearly all the sulphur dissipated in the form of sulphurous acid gas: a little sulphuret, however, remains undecomposed. The matter is then mixed either with tartar, or with charcoal impregnated with a concentrated solution of carbonate of soda, and the mixture introduced into crucibles, which are placed in a melting furnace. Heat being applied, the charcoal reduces the oxide of antimony, while the alkali unites with the undecomposed sulphuret, and forms with it melted scoriæ, which cover the reduced metal and diminish its loss by volatilization. The metal obtained is then fused a second time for the purpose of purification.

In Scotland, the sulphuret of antimony is decomposed by the superior affinity of iron for the sulphur; but the metal obtained by this process is of bad quality.

Antimony is imported into the United States principally from France, from the ports of Havre and Bordeaux, packed in casks, and most of it arrives at New York. A portion is also shipped from Trieste, from Holland, and occasionally from Cadiz. The Spanish antimony is generally in the form of pigs; the French, in circular cakes of about ten inches in diameter, flat on one side and convex on the other; and the English, in cones. The French is most esteemed. Very little English antimony is at present imported into the United States.

Properties, &c. The time of the discovery of antimony is not known; but, according to Berzelius and Thenard, Basil Valentine was the first to describe the method of obtaining it, in his work, entitled *Currus Triumphalis Antimonii*, published towards the end of the fifteenth century. It is a brittle, brilliant metal, ordinarily of a lamellated texture, and of a silver-white colour when pure, but bluish-white as it occurs in commerce. When rubbed between the fingers, it communicates to them a sensible odour. Its sp. gr. is 6.7, and its fusing point 810° or about a red heat. On cooling after fusion, it assumes a crystalline structure, and an appearance on the surface bearing some resemblance to a fern leaf. When strongly heated it takes fire, and burns with emission of white vapours, consisting of protoxide, formerly called *argentine flowers of antimony.* A small portion being fused, and then thrown from a moderate height upon a plane surface, divides into numerous globules, which burn rapidly as they pass through the air. It forms three combinations with oxygen; one oxide,—sesquioxide of antimony, and two acids,—antimonious and antimonic acids. Its equivalent number, according to Berzelius, is 64.6; and the sesquioxide contains one and a half; antimonious acid two, and antimonic acid two and a half equiv. of oxygen. The sesquioxide only is a true salifiable base, and it is this oxide which is uniformly present in the active medicinal preparations of this metal. It will be noticed under another head. (See *Antimonii Oxydum Nitromuriaticum*, Dub.) *Antimonic acid* is in the form of a lemon-coloured powder, which may be prepared by oxidizing the metal by digestion in nitric acid, and then driving off the excess of nitric acid by a heat not exceeding 600°. When exposed to a red heat, it parts with oxygen, and is converted into *antimonious acid.* This is a white powder, and, though medicinally inert, frequently forms a large proportion of the preparation called antimonial powder. (See *Pulvis Antimonialis.*)

The following table exhibits a view of the different officinal preparations of antimony:—

I. SULPHURETTED:—
  1. Antimonii Sulphuretum, *U.S.*, *Lond.*, *Dub.;* Sulphuretum Antimonii, *Ed.*
  2. Antimonii Sulphuretum Præparatum, *U.S.*, *Dub.;* Sulphuretum Antimonii Præparatum, *Ed.*
  3. Antimonii Sulphuretum Præcipitatum, *U.S.*, *Lond.;* Sulphuretum Antimonii Præcipitatum, *Ed.;* Sulphur Antimoniatum Fuscum, *Dub.*

II. OXIDIZED:—
  1. *Sesquioxide.* Antimonii Oxydum Nitromuriaticum, *Dub.*
  2. *Sesquioxide combined with sulphuret.* Antimonii Vitrum, *Lond.*
  3. *Sesquioxide combined with tartaric acid and potassa.* Antimonii et Potassæ Tartras, *U.S.*, *Dub.;* Antimonium Tartarizatum, *Lond.;* Tartras Antimonii, *Ed.* *Dissolved in wine.* Vinum Antimonii, *U.S.;* Vinum Tartratis Antimonii, *Ed.* *Dissolved in diluted alcohol.* Vinum Antimonii Tartarizati, *Lond.;* Liquor Tartari Emetici, *Dub.* *Mixed with lard.* Unguentum Tartari Emetici, *Dub.*
  4. *Sesquioxide and antimonious acid mixed with phosphate of Lime.* Pulvis Antimonialis, *Lond.*, *Dub.;* Oxidum Antimonii cum Phosphate Calcis, *Ed.*

In Pharmacy, antimony is not much used in the metallic state; the sulphuret being the source, either directly or indirectly, of nearly all its medicinal preparations. (See *Antimonii Sulphuretum.*)

ANTIMONII SULPHURETUM. *U.S.*, *Lond.*, *Dub.*

Sulphuret of Antimony.

Off. Syn. SULPHURETUM ANTIMONII. *Ed.*

Crude antimony, Artificial sulphuret of antimony; Antimoine sulphuré, *Fr.;* Schwefelantimon, Schwefelspiessglas, *Germ.;* Solfuro d'antimonio, *Ital.;* Antimonio crudo, *Span.*

Preparation, &c. The officinal sulphuret of antimony of the Pharmacopœias, is a sesquisulphuret of the metal, and is uniformly placed in the list of the materia medica as an article to be purchased by the apothecary. It is obtained from the native sulphuret, by far the most abundant ore of this metal, by different processes of purification, of which the following is an outline of that generally pursued. The ore is pounded and placed in earthen pots, with perforated bottoms, which are made to rest on others, half buried in the earth. The upper pots are surrounded with wood, which is then kindled. By its combustion the sulphuret is quickly melted, and runs down into the lower pots, leaving the stony and earthy impurities behind. A better process is to use slightly conical earthenware tubes, fixed vertically in a kind of reverberatory furnace, in place of the earthen pots. This arrangement affords facilities for removing the residue of the operation, and permits the melted sulphuret to run out from the furnace, without interrupting the fire, and consequently without loss of time or fuel.

Properties, &c. Sulphuret of antimony is mostly prepared in France and Germany, and comes to the United States principally from the ports of France. It is called in commerce antimony, or crude antimony, and occurs in fused roundish masses, denominated loaves. These are dark-gray externally, and exhibit internally, when broken, a brilliant steel-gray colour, and a radiated or fibrous crystalline texture. Their goodness depends upon their compactness and weight, the largeness and distinctness of the fibres, and their total volatility by heat. The quality of the sulphuret cannot well be judged of, except in mass; hence it ought never to be bought in powder. The powder of the pure sulphuret is reddish-brown; but that of the commercial sulphuret is almost always black. The most usual impurities are lead, iron, and arsenic. Lead may be detected by the texture of the loaves being foliated and indistinctly striated; iron, by a brown colour being produced by deflagration with nitre; and arsenic, by its peculiar smell when the sulphuret is heated. According to Serullas, all the antimonial preparations, except tartar emetic and butter or chloride of antimony, contain a minute portion of arsenic. Tartar emetic is an exception, because, according to this chemist, it separates entirely, in the act of crystallizing, from any minute portion of arsenic in the materials from which it is prepared; the poisonous metal being left behind in the mother-waters of the process.

Composition. Sulphuret of antimony consists of one equivalent of antimony 64.6, and one and a half equiv. of sulphur 24.15=88.75.

Pharmaceutical Uses. Sulphuret of antimony requires to be levigated in order to fit it for exhibition as a medicine. Processes are accordingly given for this purpose in the United States, Edinburgh, and Dublin Pharmacopœias, but not in the London. The medical properties of sulphuret of antimony will accordingly be noticed under the head of the prepared sulphuret, (See *Antimonii Sulphuretum Præparatum.*)

Sulphuret of antimony is used pharmaceutically in a number of preparations. Besides being employed to obtain the prepared sulphuret as just mentioned, and the glass of antimony, (See *Antimonii Vitrum,*) it is used in the following preparations:—Antimonii Sulphuretum Præcipitatum, *Lond.;* Pulvis Antimonialis, *Lond., Ed.;* Tartras Antimonii, *Ed.* In all other preparations in which sulphuretted antimony is required, the *prepared sulphuret* is employed. B.

◆

ANTIMONII VITRUM. *Lond.*

Glass of Antimony.

Verre d'antimoine, *Fr.;* Spiessglanzglass, *Germ.;* Vetro di antimonio, *Ital.;* Vidrio de antimonio, *Span.*

Of the different Pharmacopœias noticed in this Dispensatory, the London is the only one which at present retains the glass of antimony. After having been omitted by the London College, it was restored in the revised edition of the Pharmacopœia in 1824, but placed in the materia medica list as an article to be purchased. It is defined by the College to be the vitrified sulphuretted oxide of antimony.

Preparation. Glass of antimony is prepared from the sulphuret by a partial roasting and subsequent fusion, conducted in the following manner. The sulphuret is reduced to a coarse powder, and strewed upon a shallow, unglazed, earthen vessel, and then heated gently and slowly, being continually stirred to prevent it from running into lumps. White vapours of sulphurous acid arise; and when these cease, the heat is increased a little to reproduce them. The roasting is continued in this manner, until, at a red heat, no more vapours are given off. The matter is then melted in a crucible with an intense heat, until it assumes the appearance of melted glass, when it is poured out on a heated brass plate.

In this process, part of the sulphur of the sulphuret is driven off by the roasting, and becomes sulphurous acid by uniting with the oxygen of the air. In the mean time, that portion of the antimony which loses its sulphur becomes oxidized; so that the roasted matter consists of undecomposed sulphuret and sesquioxide of antimony; and these, by uniting during the fusion, form the glass.

Properties. Glass of antimony is generally in thin irregular pieces, exhibiting a vitreous fracture, and having a metallic steel-gray lustre. When well prepared, it is transparent, and upon being held between the eye and the light, appears of a rich orange-red or garnet colour. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but soluble in acids and in cream of tartar, with the exception of a few red flocculi to be mentioned presently.

Composition, &c. The essential constituents of glass of antimony are the sesquioxide and sulphuret united in variable proportions. When of good quality, it contains about eight parts of sesquioxide to one of sulphuret. According to Berzelius, the basis of the preparation is a definite compound of one equivalent of sesquioxide, and two equiv. of sesquisulphuret of antimony, corresponding with the pure crocus of antimony; while the glass itself is a mixture of this with the sesquioxide in excess when it is transparent and of good quality, and with the sesquisulphuret in excess, when it is black and opaque, and therefore inferior. The flocculi, alluded to in the preceding paragraph, consist of this definite compound, which corresponds also with the native red antimony of mineralogists.

Glass of antimony, as usually prepared, contains about five per cent. of silica, and three of peroxide of iron. These impurities are almost invariably present. When good, it is dissolved, with the exception of the red flocculi already referred to, by strong muriatic acid. An excess of silica is known by the acid leaving a gelatinous residuum; and iron may be detected by ferrocyanate of potassa, and its amount judged of by the bulk of the precipitate, or the depth of its colour. Sometimes glass of lead is sold for glass of antimony; a fraud easily detected by the difference in sp. gr. between the two substances; the glass of lead weighing nearly 7, while the density of the glass of antimony is not quite 5. It may also be discovered by boiling the suspected article with cream of tartar; when, if it be glass of lead, it will turn black, without generating tartar emetic.

Medical Properties and Pharm. Uses. Glass of antimony is an active antimonial, formerly much employed; but at the present day, owing to its variable composition and uncertain operation, is entirely laid aside. When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture is roasted over a slow fire, with constant stirring, until it ceases to exhale vapours, a coal-like, pulverizable mass is formed, which is the *Cerated Glass of Antimony*, a preparation formerly included in the Edinburgh Pharmacopœia, but long since very properly expunged from that work. The Glass of antimony is introduced into the London Pharmacopœia, to be employed in the process of that College for the preparation of tartar emetic. (See *Antimonium Tartarizatum*, Lond.) B.

APOCYNUM ANDROSÆMIFOLIUM. *U.S. Secondary.*

Dog's-bane.

"Apocynum androsæmifolium. Radix. *The root.*" *U. S.*

APOCYNUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Apocyneæ.

Gen. Ch. *Calyx* very small, five-cleft, persistent. *Corolla* campanulate, half five-cleft, lobes revolute, furnished at the base with five dentoid glands alternating with the stamens. *Anthers*, connivent, sagittate, cohering to the stigma by the middle. *Style* obsolete. *Stigma* thick and acute. *Follicles* long and linear. *Seed* comose. *Nuttall.*

Apocynum androsæmifolium. Willd. *Sp. Plant.* i. 1259; Bigelow, *Am. Med. Bot.* ii. 148. The Dog's-bane is an indigenous, perennial, herbaceous plant, from three to six feet in height, and abounding in a milky juice, which exudes when any part of the plant is wounded. The stem is erect, smooth, simple below, branched above, usually red on the side exposed to the sun, and covered with a tough fibrous bark. The leaves are opposite, petiolate, ovate, acute, entire, smooth on both sides, and two or three inches long. The flowers are white, tinged with red, and grow in loose, nodding, terminal or axillary cymes. The peduncles are furnished with very small acute bractes. The tube of the corolla is longer than the calyx, and its border spreading. The fruit consists of a pair of long, linear, acute follicles, containing numerous imbricated seeds, attached to a central receptacle, and each furnished with a long seed-down.

The plant flourishes in all parts of the United States, from Canada to Carolina. It is found along fences and the skirts of woods, and flowers in June and July. The root is the part employed.

This is large, and like other parts of the plant contains a milky juice.

Its taste is unpleasant and intensely bitter. Bigelow inferred from his experiments that it contained bitter extractive, a red colouring matter soluble in water and not in alcohol, caoutchouc, and volatile oil.

Medical Properties. The powder of the recently dried root acts as an emetic in the dose of thirty grains; and is said to be sometimes employed by practitioners in the country for this purpose. By Dr. Zollickoffer it is considered a useful tonic, in doses of from ten to twenty grains. Dr. Bigelow states that its activity is diminished, and eventually destroyed by keeping. It is among the remedies employed by the Indians in lues venerea. W.

APOCYNUM CANNABINUM. *U.S. Secondary.*

Indian Hemp.

"Apocynum cannabinum. Radix. *The root.*" *U.S.*

Apocynum. See APOCYNUM ANDROSÆMIFOLIUM.

Apocynum cannabinum. Willd. *Sp. Plant.* i. 1259; Knapp, *Am. Med. Rev.* iii. 197. In general appearance and character, this species bears a close resemblance to the preceding. The stems are herbaceous, erect, branching, of a brown colour, and two or three feet in height; the leaves are opposite, oblong-ovate, acute at both ends, and somewhat downy beneath; the cymes are paniculate, many-flowered, and pubescent; the corolla small and greenish, with a tube not longer than the calyx, and with an erect border; the internal parts of the flower pinkish or purple. The plant grows in similar situations with the *A. androsæmifolium*, and flowers about the same period. Like that species, it abounds in a milky juice, and has a tough fibrous bark, which, by maceration, affords a substitute for hemp. From this circumstance the common name of the plant was derived. The root is the part designated by the United States Pharmacopœia, in the last edition of which this species was first recognised as officinal.

It is horizontal, five or six feet in length, about one-third of an inch thick, dividing near the end into branches which terminate abruptly, of a yellowish-brown colour when young, but dark chestnut when old, of a strong odour, and a nauseous, somewhat acrid, permanently bitter taste. The internal or ligneous portion is yellowish-white, and less bitter than the exterior or cortical part. The fresh root, when wounded, emits a milky juice, which concretes into a substance closely resembling caoutchouc. In the dried state, it is brittle and readily pulverized, affording a powder like that of ipecacuanha. According to Dr. Knapp* it contains a bitter principle, extractive, tannin, gallic acid, resin, wax, caoutchouc, fecula, lignin, and a peculiar principle upon which its activity depends, and which he proposes to call *apocynin.* Dr. Griscom by a recent analysis has obtained similar results, with the addition of gum to the other ingredients. The root yields its virtues to water and alcohol, but according to Dr. Griscom, most readily to the former.

Medical Properties and Uses. Indian hemp is powerfully emetic and cathartic, sometimes diuretic, and like other emetic substances, promotes diaphoresis and expectoration. It produces much nausea, diminishes the frequency of the pulse, and appears to induce drowsiness independently of the exhaustion consequent upon vomiting. The disease in which it has been found most beneficial is dropsy. An aggravated case of ascites, under the care of Dr. Joseph Parrish of Philadelphia, was completely cured by the decoction of the plant, which acted as a powerful hydragogue cathartic. Dr. Knapp also found it useful in a case of dropsy. Other instances of its efficacy in this complaint have been recently published by Dr. Griscom of New York. (*Am. Journ. of Med. Sciences*, xii. 55.)

---

* See an Inaugural Dissertation by M. L. Knapp, M. D., in the Am. Med. Review, Philadelphia, 1826. Vol. iii. p. 197.

From fifteen to thirty grains of the powdered root will generally produce copious vomiting and purging. The decoction is a more convenient form of administration. It may be prepared by boiling half an ounce of the dried root in a pint and a half of water to a pint, of which from one to two fluidounces may be given two or three times a day, or more frequently if requisite. The watery extract, in doses of three or four grains three times a day, will generally act on the bowels. W.

AQUA. *U.S.*

Water.

ὕδωρ, *Gr.;* Eau, *Fr.;* Wasser, *Germ.;* Acqua, *Ital.*, Agua, *Span.*

Water stands very properly in the United States Pharmacopœia, as an article of the materia medica, on account of its great importance as a medical and pharmaceutical agent. In the British Pharmacopœias it has been unaccountably omitted from the list of the materia medica, although it is constantly employed in the preparations. It is one of the most abundant productions in nature, and plays an important part in the economy of the universe. It is more or less concerned in almost all the changes which take place in inorganic matter, and is essential to the growth and existence of living beings, whether animal or vegetable. In treating of a substance of such diversified agency, our limits will only allow of a sketch of its properties and modifications. We shall speak of it under the several heads of *pure water*, *common water*, and *mineral waters*.

PROPERTIES OF PURE WATER. Water, in a pure state, is a transparent liquid, without colour, taste, or smell. Its sp. gr. is assumed to be unity by common consent, and forms the term of comparison for that of all solids and liquids. A cubic inch of it, at the temp. of 60°, weighs very nearly 252.5 grains. It is compressible to a small extent, as was first proved by Canton, and afterwards, in an incontestible manner, by Perkins. Reduced in temp. to 32°, it becomes a solid or ice; and raised to that of 212°, an elastic fluid called steam. In the state of steam its bulk is increased nearly 1700 fold, and its sp. gr. so far diminished as not to be much more than half as great as that of atmospheric air. At the temp. of 39° its density is at the maximum; and consequently, setting out from this point, it is increased in bulk by being either heated or cooled. It has the power of dissolving more or less of all the gases, and, among the rest, of common air, the constituents of which are always present in natural water. It is uniformly present in the atmosphere, in the form of an invisible vapour, even in the driest weather, and exerts, by its variable amount at different times, an important influence on the animal economy.

Water unites with other bodies either in the liquid or solid form; in the former case producing solutions, in the latter hydrates. It is the most universal solvent known, and on this property mainly depends its great influence in the operations of nature.

Water consists of one equivalent of hydrogen 1, and one of oxygen 8 = 9; or in volumes, of one volume of hydrogen, and half a volume of oxygen, condensed into one volume of aqueous vapour or steam. On these data, it is easy to calculate the sp. gr. of steam, for its density will be .0689 (sp. gr. of hydrogen) + .5512 (half the sp. gr. of oxygen) = .6201.

COMMON WATER. From the extensive solvent powers of water, it may be readily inferred, that, in its natural state, it must be more or less contaminated with foreign matter. This is found to be the case; and, according to the nature of the strata through which it percolates, it becomes variously impregnated. When the foreign substances present are in so small amount, as not very materially to alter its taste and other sensible qualities, it constitutes the different varieties of *common water*.

Common water possesses almost innumerable shades of difference, as obtained from different localities and sources; but all its varieties may be conveniently arranged under the two heads of soft and hard. A *soft water* is one which contains but inconsiderable impurities, and which, when used in washing, does not curdle soap. By a *hard water* is understood a variety of water which contains sulphate of lime, and, therefore, curdles soap, and is unfit for domestic purposes. Tincture of soap is a convenient and useful test for ascertaining the quality of water. In distilled water it produces no effect; in soft water, only a slight opalescence; and in a hard water, a milky appearance. This latter appearance is due to the formation of an insoluble compound between the oil of the soap and the lime of the sulphate of lime.

The most usual foreign substances in common water, besides oxygen and nitrogen, and matters held in a state of mechanical suspension, are carbonic acid, sulphate and carbonate of lime, and chloride of sodium (common salt). Carbonic acid is detected by lime-water, which produces a precipitate before the water is boiled, but not afterwards, as ebullition drives off this acid. The presence of sulphate of lime is shown by precipitates being produced by nitrate of baryta, and after ebullition, by oxalate of ammonia. The first test shows the presence of sulphuric acid, and the latter, of lime not held in solution by carbonic acid. Carbonate of lime can be present only by being held in solution by an excess of carbonic acid, and is detected by boiling the water, which causes it to precipitate. Nitrate of silver will produce a precipitate, if any chloride or muriate be present; and in all ordinary cases the particular one present may be assumed to be common salt.

It is generally supposed that the oxygen and nitrogen present in natural waters are in the same proportion as in atmospheric air; but for the most part the oxygen is in excess. In atmospheric air, the oxygen amounts to 20 per cent. in volume; but the usual gaseous mixture expelled from fresh water by boiling contains about 32 per cent. of this gas. The cause of this difference in proportion, is, that water has a greater affinity for oxygen than nitrogen, and consequently takes up proportionably more of the former from the atmosphere.

Common water is also divided into varieties according to its source. Thus we have *Rain*, *Snow*, *Spring*, *River*, *Well*, *Lake*, and *Marsh Water*. This division is not so practical, however, as that into *soft* and *hard;* as the source of the water is not always indicative of its quality. We shall notice these varieties in a general manner.

Rain and Snow Waters are the purest kinds of natural water, being, in effect, produced by a kind of natural distillation. Rain water, to be obtained as pure as possible, must be collected in large vessels in the open fields at a distance from houses, and some time after the rain has commenced falling, otherwise it will be contaminated with the dust which floats in the atmosphere, and other impurities derived from roofs. It may be obtained tolerably pure, even in large cities, by taking advantage of a heavy rain, and, after it has descended for a considerable time and washed away every impurity, collecting it as it falls from the roofs and spouts.

Rain water ordinarily contains atmospheric air; and, according to Liebig, a little nitric acid, if it descended during a storm. It is said to contain also a trace of chloride of calcium; but this is highly improbable, on account of the fixed nature of this salt. Snow water has a peculiar taste, which was formerly supposed to depend on the presence of air more oxygenous than that of the atmosphere; but in point of fact, when newly melted it contains no air, and this accounts for its vapid taste. After exposure to the air, however, for some time, it takes up the constituent gases of the atmosphere like other natural waters. Both rain and snow water are sufficiently pure for employment in most chemical operations.

Spring Water (aqua fontana) depends entirely for its quality on the strata through which it flows, being purest when it passes through sand or gravel. It almost always contains a trace of common salt, and generally other impurities, which vary according to the locality of the spring.

River Water (aqua fluviatilis), generally speaking, is less impregnated with saline matter than spring water; on account of its being made up in considerable part of rains, and of its volume bearing so large a proportion to the surface of its bed. On the other hand, it is much more apt to have mechanically suspended in it, certain insoluble matters of a vegetable and earthy nature, which impair its transparency.

Well Water, like that from springs, is liable to contain various impurities. As a general rule, the purity of the water of a well will be in proportion to its depth, and the constancy with which it is used. The Artesian or overflowing wells, on account of their great depth, generally afford a very pure water.

Lake Water cannot be characterized as having any invariable qualities. In most of the lakes in the United States it constitutes a very pure and wholesome water. This remark is particularly applicable to our great lakes.

Marsh Water is generally stagnant, and contains vegetable remains undergoing decomposition. It is an unwholesome variety of water, and ought never to be used for medicinal purposes.

The term *Aqua*, in the U.S. Pharmacopœia, may be considered as designating any natural water of good average quality. A good water may be known by its being lively, limpid, and without smell. It answers well for the cooking of vegetables, and does not curdle soap. Upon the addition of nitrate of baryta, nitrate of silver, or oxalate of ammonia, its transparency is but slightly affected; and upon being evaporated to dryness, it leaves but an inconsiderable residue.

Water should never be kept in leaden cisterns, on account of the risk of its dissolving a small portion of lead. This risk is greater in proportion to the original purity of the water; for it is found, that the presence of a minute portion of saline matter, as for example of a muriate or sulphate, protects the water from the slightest metallic impregnation. The protection is afforded by the formation of an insoluble film on the surface of the lead, as a consequence of the decomposition of the saline matter. (See *Christison on Poisons.*)

The Schuylkill water introduced into the City of Philadelphia possesses all the characteristics of a good water, except that it is occasionally turbid after heavy rains. Accordingly, it may be used pharmaceutically in all cases in which "water" is directed as contradistinguished from "distilled water." A brackish or hard water ought never to be employed. For some pharmaceutical processes, however, no natural water is deemed sufficiently pure; and hence the necessity of resorting to a process for its purification. This is effected by distillation, and accordingly all the Pharmacopœias give a formula for distilled water. (See *Aqua Destillata.*)

MINERAL WATERS. Natural waters, when they are so far impregnated with foreign substances as to have a decided taste and a peculiar operation on the animal economy, are called *Mineral Waters.* These are necessarily very diversified in their nature, but they are conveniently arranged for description under the four heads of *carbonated*, *sulphuretted*, *chalybeate*, and *saline.*

1. *Carbonated waters* are characterized by containing an excess of carbonic acid, which gives them a sparkling appearance, and the power of reddening litmus paper. These waters frequently contain the carbonates of lime, magnesia, and iron, which are held in solution by the excess of carbonic acid. The waters of Seltzer, Spa, and Pyrmont in Europe, and of the sweet springs in Virginia, belong to this class.

2. *Sulphuretted waters* are such as contain sulphuretted hydrogen, and are distinguished by the peculiar fetid smell of that gas, and by their yielding a brown precipitate with the salts of lead or silver. Examples of this kind of mineral water are furnished by the waters of Aix la Chapelle and Harrowgate in Europe, and those of the white, red, and salt sulphur springs in Virginia.

3. *Chalybeate waters* are characterized by a strong inky taste, and by striking a black colour with the infusion of galls, and a blue one with ferrocyanate of potassa. The iron is generally in the state of protocarbonate held in solution by excess of carbonic acid. By standing, the carbonic acid is given off, and the protoxide becomes a hydrated peroxide of an ochreous colour, and is precipitated. The principal chalybeate waters are those of Tunbridge and Brighton, in England, and Balston Spa, Bedford, Pittsburgh, and Brandywine, in the United States.

4. *Saline waters* are those, the prominent properties of which depend upon saline impregnation. The salts most usually present are the sulphates, muriates, and carbonates of lime, magnesia, and soda. Potassa is occasionally present, and lithia has been detected by Berzelius in the spring of Carlsbad, in Germany. Bromine exists in considerable quantity in the saline at Theodorshalle, in Germany, and iodine is not unfrequently present. The water of the Congress spring at Saratoga, in the state of New York, contains, according to Dr. Steel, both iodine and bromine in small quantity. The principal saline waters are those of Seidlitz in Bohemia, Cheltenham and Bath in England, and Harrodsburg and Saratoga in the United States. To these may be added, a most important saline water, that of the ocean.

We subjoin a summary view of the composition of most of the mineral waters enumerated under the foregoing heads, with the authority for each analysis.

CARBONATED. *Seltzer.* In a wine pint. Carbonic acid 17 cubic inches. *Solid contents;*—carbonate of soda 4 grs.; carbonate of magnesia 5; carbonate of lime 3; chloride of sodium 17. Total 29 grs. *Bergmann.*

Spa. In a wine pint. Carbonic acid 13 cubic inches. *Solid contents;*—carbonate of soda 1.5 grs.; carbonate of magnesia 4.5; carbonate of lime

1.5; chloride of sodium 0.2; oxide of iron 0.6. Total 8.3 grs. *Bergmann.*

Pyrmont. In a wine pint. Carbonic acid 26 cubic inches. *Solid contents;*—carbonate of magnesia 10 grs.; carbonate of lime 4.5; sulphate of magnesia 5.5; sulphate of lime 8.5; chloride of sodium 1.5; oxide of iron 0.6. Total 30.6 grs. *Bergmann.*

SULPHURETTED. *Aix la Chapelle.* In a wine pint. Sulphuretted hydrogen 5.5 cubic inches. *Solid contents;*—carbonate of soda 12 grs.; carbonate of lime 4.75; chloride of sodium 5. Total 21.75 grs. *Bergmann.*

Harrowgate old well. In a wine gallon. *Gaseous contents;*—sulphuretted hydrogen 14 cubic inches; carbonic acid 4.25; nitrogen 8; carburetted hydrogen 4.15. Total 30.4 cubic inches. *Solid contents;*—chloride of sodium 752 grs.; muriate of lime 65.75; muriate of magnesia 29.2; bicarbonate of soda 12.8. Total 859.75 grs. *English West. Quart. Journ.*

White Sulphur. In a wine gallon. *Gaseous contents;*—sulphuretted hydrogen 2.5 cubic inches; carbonic acid 2; oxygen 1.448; nitrogen 3.552. Total 9.5 *Solid contents in a pint;*—sulphate of magnesia 5.588 grs.; sulphate of lime 7.744; carbonate of lime 1.150; muriate of lime 0.204; chloride of sodium 0.180; oxide of iron a trace; loss 0.410. Total 15.276 grs. *Prof. William B. Rogers.*

CHALYBEATE. *Tunbridge.* In a wine gallon. *Solid contents;*—chloride of sodium 2.46 grs.; muriate of lime 0.39; muriate of magnesia 0.29; sulphate of lime 1.41; carbonate of lime 0.27; oxide of iron 2.22; traces of manganese, vegetable fibre, silica, &c. 0.44; loss 0.13. Total 7.61 grs. *Scudamore.*

Brighton. In a wine pint. Carbonic acid 2.5 cubic inches. *Solid contents;*—sulphate of iron 1.80 grs.; sulphate of lime 4.09; muriate of soda 1.53; muriate of magnesia 0.75; silica 0.14; loss 0.19. Total 8.5 grs. *Marcet.*

Cheltenham, (*chalybeate.*) In a wine pint. *Gaseous contents;*—carbonic acid 2.5 cubic inches. *Solid contents;*—carbonate of soda 0.5 grs.; sulphate of soda 22.7; sulphate of magnesia 6; sulphate of lime 2.5; chloride of sodium 41.3; oxide of iron 0.8. Total 73.8 grs. *Brande and Parkes.*

Balston Spa. Sans Souci Spring. In a wine gallon. *Solid contents;*—chloride of sodium 143.733 grs.; bicarbonate of soda 12.66; bicarbonate of magnesia 39.1; carbonate of lime 43.407; carbonate of iron 5.95; hydriodate of soda 1.3; silica 1. Total 247.15 grs. *Steel.*

Bedford. Anderson's Spring. In a wine gallon. Carbonic acid 74 cubic inches. *Solid contents;*—sulphate of magnesia 80 grs.; sulphate of lime 14.5; chloride of sodium 10; muriate of lime 3; carbonate of iron 5; carbonate of lime 8. Total 120.5 grs. *Church.*

SALINE. *Seidlitz.* In a wine pint. *Solid contents;*—carbonate of magnesia 2.5 grs.; carbonate of lime 0.8; sulphate of magnesia 180; sulphate of lime 5; muriate of magnesia 4.5. Total 192.8 grs. *Bergmann.*

Cheltenham, (*pure saline.*) In a wine pint. *Solid contents;*—sulphate of soda 15 grs.; sulphate of magnesia 11; sulphate of lime 4.5; chloride of sodium 50. Total 80.5 grs. *Parkes and Brande.*

Bath. In a wine pint. Carbonic acid 1.2 cubic inches. *Solid contents;*—carbonate of lime 0.8 grs.; sulphate of soda 1.4; sulphate of lime 9.3, chloride of sodium 3.4; silica 0.2; oxide of iron a trace. Total 15.1 grs. *Phillips.*

Saratoga. Congress Spring. In a wine gallon. *Gaseous contents;*—carbonic acid 311 cubic inches; atmospheric air 7. Total 318 cubic inches. *Solid contents;*—chloride of sodium 385 grs.; hydriodate of soda 3.5; bicarbonate of soda 8.982; bicarbonate of magnesia 95.788; carbonate of lime 98.098; carbonate of iron 5.075; silica 1.5; hydrobromate of potassa a trace. Total 597.943 grs. *Steel.**

Sea Water. In a wine pint. Chloride of sodium 180.5 grs.; muriate of magnesia 18.3; muriate of lime 5.7; sulphate of magnesia 21.6. Total 226.1 grs. *Murray.*

Medical and Dietetic Properties of Water.—Water is a substance of the first necessity to living beings, whether vegetable or animal. In animals there exists an instinctive desire for it, to repair the waste of the fluids which is constantly taking place in the animal economy. It constitutes the basis of nearly all the secretions, and nine-tenths of the weight of the blood. In short, it is nature's agent for producing the liquid state; and it is the only diluent proper in a state of health.

Water as a remedy is highly important, though we are apt to overlook its agency, on account of our familiarity with its use. When taken into the stomach, it acts by its temperature, by its bulk, and by being absorbed. When of the temperature of about 60°, it gives no positive sensation either of heat or cold; between 60° and 45°, it creates a cool sensation; and below 45°, a decidedly cold one. Between 60° and 100°, it relaxes the fibres of the stomach, and is apt to produce nausea, particularly if the effect of bulk be added to that of temperature. By its bulk and solvent powers, it often allays irritation by diluting the acrid contents of the stomach and bowels, and favouring their final expulsion; and by its absorption, it promotes the secretion of urine and cutaneous transpiration. Indeed, its influence is so great in the latter way, that it may be safely affirmed, that sudorifics and diuretics will not produce their proper effect unless assisted by copious dilution.

Water, externally applied as a bath, is also an important remedy. It may act by its own specific effects as a liquid, or as a means of modifying the heat of the body. It acts in the latter way differently, according to the particular temperature at which it may be applied. When this is above 97°, it constitutes either the vapour or hot bath; when between 97° and 85°, the warm bath; between 85° and 65°, the tepid bath; and between 65° and 32°, the cold bath.

The general action of the vapour bath is to accelerate the circulation, and produce profuse sweating. It acts locally on the skin by softening and relaxing its texture. In stiffness of the joints, and various diseases of the skin, it has often proved beneficial. The late Dr. Duncan stated that he had seen scaly cutaneous diseases, which had resisted for years every other treatment, become quickly cured by its use.

The hot, like the vapour bath, is decidedly stimulant. By its use, the pulse becomes full and frequent, the veins turgid, the face flushed, the skin red, and the respiration quickened. If the temperature be high, and the constitution peculiar, its use is not without danger; as it is apt to produce a feeling of suffocation, violent throbbing in the temples, and vertigo, with tendency to apoplexy. When it acts favourably, it depletes actively from the skin by producing profuse sweating.

The warm bath, though below the animal heat, nevertheless produces a sensation of warmth, as its temperature is above that of the surface. It diminishes the frequency of the pulse, especially if previously accelerated, renders the respiration slower, lessens the heat of the body, and relaxes the skin. The warm bath cannot be deemed, strictly speaking, a stimulant; but by relieving certain diseased actions and states, accompanied by morbid irritability, it forms an excellent soothing remedy, producing a disposition to sleep. It is proper, in febrile and exanthematous diseases, in which the pulse is frequent, and the skin preternaturally hot and dry, and where the general condition is characterized by restlessness. It is contra-indicated in diseases of the head and chest.

---

* We have taken our notices of the mineral waters of the United States from a valuable work on Baths and Mineral Waters, by Dr. John Bell, and from the interesting treatise on the Mineral Waters of Saratoga and Balston, by Dr. John H. Steel; both published in 1831.

The tepid bath, from its temperature, is not calculated to have much modifying influence on the heat of the body. Its peculiar effects are to soften and cleanse the skin, and promote insensible perspiration.

The cold bath acts differently according to its temperature and manner of application, and the condition of the system to which it is applied. When of low temperature and suddenly applied, it acts primarily as a stimulant, by the sudden and quick manner in which the caloric is abstracted, or made to pass through the substance of the body; next, as a tonic, by removing the opponent to attraction which tends to condense the living fibre; and finally, as a sedative. If it were applied at a temperature just sufficient to excite a cool sensation, and this temperature gradually and imperceptibly lowered, it is probable that the cold bath would act exclusively as a sedative.

From the above explanations, it may be easily understood that the cold bath will act very differently under different circumstances. It is often useful in diseases of relaxation and debility, when practised by affusion or plunging. But it is essential to its efficacy and safety in these cases, that the stock of vitality should be sufficient to create, immediately after its use, those general sensations of warmth and invigoration included under the term reaction. It has also been used with advantage by the late Dr. Currie of Liverpool, in the form of affusion, in certain febrile diseases, especially scarlatina. To make it safe in these diseases, however, the heat must be steadily above the natural standard; and the patient must be free from all sense of chilliness, and not in a state of profuse perspiration.

Cold water is frequently applied as a sedative in local inflammations, and as a means of restraining hemorrhage. It is, however, inadmissible in inflammations of the chest.

Pharm. Uses. Water is the most extensive pharmaceutical agent which we possess. It is employed in a vast number of preparations, as a means of promoting chemical action by its solvent powers. It is more or less present in all the liquid forms of medicines, and is the sole menstruum in the medicated waters, decoctions, and infusions.

ARALIA NUDICAULIS. *U.S. Secondary.*

False Sarsaparilla.

"Aralia nudicaulis. Radix. *The Root.*" *U.S.*

Aralia. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Araliaceæ.

Gen. Ch. *Flowers* umbelled. *Calyx* five-toothed, superior. *Petals* five. *Stigma* sessile, subglobose. *Berry* five-celled, five-seeded. *Torrey.*

Aralia nudicaulis. Willd. *Sp. Plant.* i. 1521; Rafinesque, *Med. Flor.* i.

53. The *false sarsaparilla, wild sarsaparilla,* or *small spikenard,* as this plant is variously called, is an indigenous perennial, with one leaf and one flower-stem springing together from the root or from a very short stalk, and seldom rising two feet in height. The leaf, which stands upon a long footstalk, is twice ternate, or once and quinate, with oblong-oval, acuminate leaflets, rounded at the base, serrate on the margin, and smooth on both surfaces. The scape or flower-stem is naked, shorter than the leaf, and terminated by three small umbels, each consisting of from twelve to thirty small yellowish or greenish flowers. The fruit consists of small round berries, about as large as those of the common elder.

The plant grows throughout the United States, from Canada to Carolina, inhabiting shady and rocky woods, and delighting in a rich soil. It flowers in May and June. The root is the officinal portion.

This is horizontal, creeping, sometimes several feet in length, about as thick as the little finger, more or less twisted, externally of a yellowish-brown colour, of a fragrant odour, and a warm, aromatic, sweetish taste. It has not been analyzed.

Medical Properties and Uses. False sarsaparilla is a gentle stimulant and diaphoretic; and is thought to exert an alterative influence over the system analogous to that of the root from which it derived its name. It is used in domestic practice, and by some practitioners in the country, as a remedy in rheumatic, syphilitic, and cutaneous affections, in the same manner and dose as the genuine sarsaparilla.

The root of the *Aralia racemosa* or *American spikenard,* though not officinal, is used for the same purposes as the A. nudicaulis, which it is said to resemble in medical properties. W.

◆

ARALIA SPINOSA. *U.S. Secondary.*

Angelica-tree Bark.

"Aralia spinosa. Cortex. *The Bark.*" *U.S.*

Aralia. See ARALIA NUDICAULIS.

Aralia spinosa. Willd. *Sp. Plant.* i. 1520. This is an indigenous arborescent shrub, variously called *angelica-tree, toothach tree,* and *prickly ash.* The last name, however, should be dropped, as it belongs properly to the *Xanthoxylum fraxineum,* and if retained might lead to confusion. The stem is erect, simple, from eight to twelve feet high, armed with numerous prickles, and furnished near the top with very large bipinnate or tripinnate leaves, which are also prickly, and are composed of oval, pointed, slightly serrate leaflets. It terminates in an ample panicle, very much branched, and bearing numerous small hemispherical umbels, in each of which are about thirty white flowers.

This species of Aralia is found chiefly in the Southern and Western States, though cultivated in the gardens of the North as an ornamental plant. It flourishes in low, fertile woods, and flowers in August and September. The bark, root, and berries are medicinal; but the first only is directed by the Pharmacopœia.

The bark is thin, grayish externally, yellowish within, of an odour somewhat aromatic, and a bitterish, pungent, acrid taste. It yields its virtues to boiling water.

Medical Properties and Uses. The virtues of *Aralia Spinosa* are those of a stimulant diaphoretic. According to Elliot, an infusion of the recent bark of the root is emetic and cathartic. The remedy is used in chronic rheumatism and cutaneous eruptions. Pursh states, that a vinous or spirituous infusion of the berries is remarkable for relieving rheumatic pains; and a similar tincture is said to be employed in Virginia with advantage in violent colic. The pungency of this tincture has also been found useful in relieving toothach.

The bark is most conveniently administered in decoction. W.

ARCTIUM LAPPA. Semina. Radix. *Dub.*

Seeds and Root of Burdock.

Off. Syn. ARCTII LAPPÆ SEMINA. ARCTII LAPPÆ RADIX. *Ed.*

Bardane, *Fr.;* Gemeine Klette, *Germ.;* Bardana, *Ital., Span.*

Arctium. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ Cinarocephalæ.

Gen. Ch. Receptacle chaffy. *Calyx* globular; the scales at the apex with inverted hooks. *Seed-down* bristly, chaffy. *Willd.*

Arctium Lappa. Willd. *Sp. Plant.* iii. 1631; Woodv. *Med. Bot.* p. 32, t. 13. The *burdock* is a biennial plant, with a simple spindleshaped root, a foot or more in length, brown externally, white and spongy within, furnished with threadlike fibres, and having withered scales near the summit. The stem is succulent, pubescent, branching, and three or four feet in height, bearing very large cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long footstalks. The flowers are purple, globose, and arranged in terminal panicles. The calyx consists of imbricated scales, with hooked extremities, by which they adhere to clothes, and to the coats of animals. The seed-down is rough and prickly, and the seeds quadrangular.

This plant is a native of Europe, and is abundant in this country, where it grows on the road sides, among rubbish, and in cultivated grounds. Pursh thinks that it was introduced. The root, which should be collected in spring, loses four-fifths of its weight by drying.

The odour of the root is weak and unpleasant, the taste mucilaginous and sweetish, with a slight degree of bitterness and astringency. Among its constituents, inulin has been found by Guibourt, and sugar by Fée.

The seeds are aromatic, bitterish, and somewhat acrid.

Medical Properties and Uses. The root is considered aperient, diaphoretic, and sudorific, without irritating properties; and has been recommended in gouty, scorbutic, venereal, rheumatic, scrofulous, leprous, and nephritic affections. To prove effectual, its use must be persevered in for a long time. It is best administered in the form of decoction, which may be prepared by boiling two ounces of the recent bruised root in three pints of water to two, and given in the quantity of a pint during the day. The seeds are diuretic, and have been used in the same complaints in the form of emulsion or powder. The dose is a drachm. The leaves have also been employed both externally and internally in cutaneous eruptions and ulcerations.

W.

ARGENTUM. *U.S., Lond., Ed., Dub.*

Silver.

Argent, *Fr.;* Silber, *Germ.;* Argento, *Ital.;* Plata, *Span.*

Silver is occasionally found in the metallic state, sometimes pure and crystallized, or in the form of vegetations, at other times combined with gold, antimony, arsenic, or mercury; but more usually it occurs in the state of sulphuret, either pure, or mixed with other sulphurets, such as those of copper, lead, and antimony. It is sometimes, though rarely, found as a chloride.

The most productive mines of silver are found on this continent, being those of Mexico and Peru; the richest in Europe are situated at Kongsberg in Norway, in Hungary, and in Transylvania. The principal ore which is worked is the sulphuret. The mineral containing silver which is most disseminated is the argentiferous galena, which is a sulphuret of lead, associated with a sulphuret of silver. No mines of silver have been found in the United States; but argentiferous galena exists in several localities. That from the mine of Ephraim Lane, seventeen miles west of New-Haven, is exceedingly rich, yielding two hundred and seventy-two ounces of silver to the ton of reduced lead. The annual product of all the silver mines in Europe and America is estimated at about eight hundred and fifty tons, of which only a twelfth or fifteenth part is furnished by Europe.

Extraction. Silver is extracted from its ores by two principal processes, *amalgamation* and *cupellation.* At Freyberg in Saxony, the ore, which is principally the sulphuret, is worked in the following manner. It is mixed with a tenth of chloride of sodium (common salt), and roasted in a reverberatory furnace: the sulphur becomes acidified, and combines with the soda, resulting from the oxidizement of the sodium, to form sulphate of soda, while the chlorine forms a chloride with the silver. The roasted mass is then reduced to very fine powder, mixed with half its weight of mercury, one-third of its weight of water, and about a seventeenth of iron in flat pieces, and subjected, for sixteen or eighteen hours, to constant agitation in barrels turned by machinery. The chlorine combines with the iron, and remains in solution as chloride of iron, while the silver forms an amalgam with the mercury. The amalgam is then subjected to pressure in leathern bags, through the pores of which the excess of mercury passes, while a solid amalgam remains behind. This is then subjected to heat in a distillatory apparatus, by means of which the mercury is separated from the pure silver, which remains behind in the form of a porous mass. In Peru and Mexico the process is somewhat similar to the above, common salt and mercury being used; but slaked lime and sulphuret of iron are also employed, with an effect which is not very obvious.

When argentiferous galenas are worked for the silver they contain, they are first reduced, and the metal obtained is subjected to the combined action of heat and a current of air on a very large and shallow cupel, called a *test,* made of spent ashes or pulverized bones. The metal undergoes fusion, and the lead becoming oxidized and vitrified, is either scraped or blown off the the test; while the silver, not being oxidizable, remains behind.

Properties. Silver is a white metal, very brilliant, malleable, and ductile. In malleability and ductility, it is inferior only to gold. It is harder than gold, but softer than copper. Its tenacity is very great, and its sp. gr. about

10.5. Exposed to a full red heat, it enters into fusion, and exhibits a brilliant appearance. It is not oxidized in the air, but contracts a superficial tarnish, in consequence of combining with sulphur. It forms but one well characterized oxide, which is of an olive colour, consisting of one equivalent of silver 108, and one equiv. of oxygen 8 = 116.

Pharm. Uses. Silver has no action on the animal economy; and is introduced into the Pharmacopœia solely for the purpose of forming nitrate of silver, the only officinal preparation of this metal.

ARMORACIA. *U.S.*

Horse-radish.

"Cochlearia armoracia. Radix recens. *The fresh root.*" *U.S.*

Off. Syn. ARMORACIÆ RADIX. Cochlearia Armoracia. Radix. *Lond.;* COCHLEARIÆ ARMORACIÆ RADIX. *Ed.;* COCHLEARIA ARMORACIA. Radix. *Dub.*

Raifort sauvage, *Fr.;* Meerrettig, *Germ.;* Rafano rusticano, *Ital.,;* Rabano rusticano, *Span.*

Cochlearia. *Sex. Syst.* Tetradynamia Siliculosa.—*Nat. Ord.* Cruciferæ.

Gen. Ch. *Silicula* emarginate, turgid, scabrous, with gibbous, obtuse valves. *Willd.*

Cochlearia Armoracia. Willd. *Sp. Plant.* iii. 451; Woodv. *Med. Bot.* p. 400. t. 145. The root of this plant is perennial, sending up numerous very large leaves, from the midst of which a round, smooth, erect, branching stem rises, two or three feet in height. The radical leaves are lance-shaped, waved, scollopped on the edges, sometimes pinnatifid, and stand upon strong footstalks. Those of the stem are much smaller, without footstalks, sometimes divided at the edges, sometimes almost entire. The flowers are numerous, white, peduncled, and form thick clusters at the ends of the branches. The calyx has four ovate, deciduous leaves, and the corolla an equal number of obovate petals, twice as long as the calyx, and inserted by narrow claws. The pod is small, elliptical, crowned with the persistent stigma, and divided into two cells, each containing from four to six seeds.

The horse-radish is a native of western Europe, growing wild on the sides of ditches and in other moist situations. It is cultivated for culinary purposes in most civilized countries, and is said to have become naturalized in some parts of the United States. Its flowers appear in June.

The root, which is officinal in its fresh state, is long, tapering, whitish externally, very white within, fleshy, of a strong pungent odour when scraped or bruised, and of a hot, biting, somewhat sweetish taste. Its virtues are imparted to water and alcohol. They depend upon a volatile oleaginous principle, which is dissipated by drying; the root becoming at first sweetish, and ultimately insipid and quite inert. Its acrimony is also destroyed by boiling. The volatile oil may be separated by distillation with water. It is pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. Besides this principle, the fresh root contains, according to Gutret, a minute quantity of bitter resin, sugar, extractive, gum, starch, albumen, acetic acid, acetate and sulphate of lime, water, and lignin. (*Geiger.*) It may be kept for some time without material injury, by being buried in sand in a cool place.

Medical Properties and Uses. Horse-radish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally applied it is a rubefacient. Its chief use is as a condiment to promote appetite, and invigorate digestion; but it is also occasionally employed as a medicine, particularly in dropsical complaints attended with an enfeebled condition of the digestive organs, and of the system in general. It has, moreover, been recommended in palsy and chronic rheumatism, both as an internal and external remedy; and in scorbutic affections is highly esteemed. Cullen found advantage in cases of hoarseness from the use of a syrup prepared from an infusion of horse-radish and sugar, and slowly swallowed in the quantity of one or two teaspoonfuls repeated as occasion demanded. The root may be given in the dose of half a drachm or more, either grated or cut into small pieces.

ARNICA. *U.S. Secondary.*

Leopard's-bane.

"Arnica montana. Planta. *The plant.*" *U.S.*

Off. Syn. ARNICÆ MONTANÆ FLORES. ARNICÆ MONTANÆ RADIX. *Ed.;* ARNICA MONTANA. Flores. Folia. Radix. *Dub.*

Arnique, *Fr.;* Berg-Wolverly, Gemeines ächtes Fallkraut, *Germ.;* Arnica montana, *Ital., Span.*

ARNICA. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. *Calyx* with equal leaflets, in a double row. *Seed-down* hairy, sessile. *Seeds* both of the disc and ray furnished with seed-down. *Receptacle* hairy. *Hayne.*

Arnica montana. Willd. *Sp. Plant.* iii. 2106; Woodv. *Med. Bot.* p. 41. t. 17. This is a perennial, herbaceous plant, having a woody, brownish, horizontal root, ending abruptly, and sending forth numerous slender fibres of the same colour. The stem is about a foot high, cylindrical, striated, hairy, and terminating in one, two, or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are of a bright green colour, and somewhat pubescent on their upper surface. The flowers are very large, and of a fine orange-yellow colour. The calyx is greenish, imbricated, with lanceolate scales. The ray consists of about fourteen ligulate florets, twice as long as the calyx, striated, three-toothed, and hairy at the base; the disc, of tubular florets, with a five-lobed margin.

This plant is a native of the mountainous districts of Europe and Siberia, and is found, according to Nuttall, in the northern regions of this continent, west of the Mississippi. It has been introduced into England, and, were there a sufficient demand for it, might no doubt be cultivated in this country; but it is very little used, and in the U.S. Pharmacopœia has been placed with the medicines not considered strictly officinal. The flowers, leaves, and root have been employed in medicine; but the flowers are usually preferred.

Properties. The whole plant, when fresh, has a strong disagreeable odour, which is apt to excite sneezing, and is diminished by desiccation. The taste is acrid, bitterish, and durable. Water extracts its virtues. Chevallier and Lassaigne have discovered in the flowers, gallic acid, gum, albumen, yellow colouring matter, an odorous resin, and a bitter principle which they consider identical with that discovered by them in the seeds of the *Cytisus Laburnum*, and hence named *cytisin.* This substance is yellow, of a bitter and nauseous taste, deliquescent, readily soluble in water and diluted alcohol, but with difficulty in strong alcohol, and insoluble in ether. In the dose of five grains it is powerfully emetic and cathartic, and is supposed to be the active principle of the plant. The flowers are said also to contain a small proportion of a blue volatile oil. According to Pfaff, the root contains volatile oil, an acrid resin, extractive, gum, and lignin.

Medical Properties and Uses. Leopard's-bane is a stimulant, directed with peculiar energy to the brain and whole nervous system, as manifested by the headach, spasmodic contractions of the limbs, and difficulty of respiration, which result from its use. It acts also as an irritant to the stomach and bowels, often producing an emetic and cathartic effect; and is said by Bergius to be diuretic, diaphoretic, and emmenagogue. It is much used by the Germans, who prescribe the flowers and root with advantage in amaurosis, paralysis, and other nervous affections. It is said to prove serviceable in that disordered condition which succeeds concussion of the brain from falls, blows, &c.; and from this circumstance has received the title of *panacœa lapsorum.* It has also been recommended in intermittent fever, dysentery, diarrhœa, nephritis, gout, rheumatism, dropsy, chlorosis, and various other complaints, in most of which it seems to have been empyrically prescribed. It appears to be peculiarly useful in diseases attended with a debilitated or typhoid state of the system, to which it is adapted by its stimulant properties. The powdered leaves are sometimes employed as a sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. The French practitioners occasionally use the flowers of arnica, though much less extensively than the German. In England and the United States the medicine is little known. It is best given in substance or infusion. The dose of the powder is from five to ten grains frequently repeated. The infusion may be prepared by digesting an ounce in a pint of water, of which from half a fluidounce to a fluidounce may be given every two or three hours. It should always be strained through linen, in order to separate the fine fibres, which might otherwise irritate the throat. The poisonous properties of the plant are said to be best counteracted by the free use of vinegar or other dilute vegetable acid. W.

Absinthe, *Fr.*; Gemeiner Wermuth, *Germ.*; Assenzio, *Ital.*; Artemisio Axénjo, *Span.*

ARTEMISIA. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. *Receptacle* sub-villous or nearly naked. *Seed-down* none. *Calyx* imbricate, with roundish, converging scales. *Corollas of the ray* none. *Willd.*

Several species of Artemisia have enjoyed some reputation as medicines. The leaves of the *A. Abrotanum* or southernwood have but recently been discharged from the Pharmacopœias. They have a fragrant odour, a warm, bitter, and nauseous taste; and were employed as a tonic, deobstruent, and anthelmintic. Similar virtues have been ascribed to the *A. Santonica.* The *A. pontica* has been occasionally substituted for common wormwood, but is weaker. The *A. vulgaris* or mugwort formerly enjoyed considerable reputation as an emmenagogue, and has recently come into some notice, in consequence of the recommendation of its root as a remedy in epilepsy by Dr. Burdach of Germany. For this purpose, it should be collected in autumn or early in the spring, and the side roots only dried for use. These should be powdered as they are wanted, the ligneous portion being rejected. The dose is about a drachm, to be administered in some warm vehicle in anticipation of the paroxysm, and to be repeated once or twice, at intervals of half an hour, till perspiration is produced, the patient being confined to bed. In the intervals, it may be given every second day. This is merely the revival of an old practice in Germany. The *A. vulgaris* of this country is thought by Nuttall to be a distinct species, and may not possess similar properties. In China, *moxa* is said to be prepared from the leaves of the *Artemisia Chinensis*, and *A. Indica*, which are for this reason ranked among the officinal plants by the Dublin College. (See *Moxa.*) The medicine known in Europe by the name of wormseed, is probably the product of different species of Artemisia. (See the succeeding article.) But the only species which requires particular description is the *A. Absinthium.*

Artemisia Absinthium. Willd. *Sp. Plant.* iii. 1844; Woodv. *Med. Bot.* p. 54. t. 22. Wormwood is a perennial plant, with herbaceous, branching, round and striated or furrowed stems, which rise two or three feet in height, and are panicled at their summit. The radical leaves are triply pinnatifid, with lanceolate, obtuse, dentate divisions; those of the stem doubly or simply pinnatifid, with lanceolate, somewhat acute divisions; the floral leaves are lanceolate; all are hoary. The flowers are of a brownish-yellow colour, hemispherical, pedicelled, nodding, and in erect racemes. The florets of the disc are numerous, those of the ray few.

This plant is a native of Europe, where it is also cultivated for medical use. It is among our garden herbs, and has been naturalized in the mountainous districts of New England. The leaves and flowering summits are the parts employed, the larger parts of the stalks being rejected. They should be gathered in July or August, when the plant is in flower.

Wormwood has a strong odour, and an intensely bitter, nauseous taste, which it imparts to water and alcohol. A dark green volatile oil, upon which the odour depends, is obtained by distillation. The constituents, according to Braconnot, are a very bitter, and an almost insipid azotized matter, an excessively bitter resinous substance, a green volatile oil, chlorophylle, albumen, starch, saline matters, and lignin. Among the saline substances, Braconnot found a combination of potassa with a peculiar acid, which he denominated *absinthic acid.*

Medical Properties and Uses. Wormwood is highly tonic, and has enjoyed great reputation as a remedy in numerous complaints attended with a debilitated condition of the digestive organs, or of the system generally. Before the introduction of Peruvian bark, it was much used in the treatment of intermittents. It has also been supposed to possess anthelmintic virtues. At present, however, it is little used in regular practice on this side of the Atlantic. A narcotic property has been ascribed to it by some writers, in consequence of its tendency to occasion headach, and when long continued, to produce disorder of the nervous system. This property is supposed to depend on the volatile oil, and therefore to be less obvious in the decoction than in the powder or infusion. The herb is sometimes applied externally, by way of fomentation, as an antiseptic and discutient. The dose of wormwood in substance is from one to two scruples; of the infusion made by macerating an ounce in a pint of boiling water, from one to two fluidounces.

Off. Prep. Extractum Artemisiæ Absinthii. *Dub.* W.

ARTEMISIA SANTONICA. Semina. *Dub.*

Seeds of Tartarian Southernwood.

Off. Syn. ARTEMISIÆ SANTONICÆ CACUMINA, *Ed.*

Barbotine, Sementine, *Fr.;* Wurmsame, *Germ.;* Seme Santo, *Ital.*

The wormseed of Europe are ascribed by the Edinburgh and Dublin Colleges, without sufficient authority, to the *Artemisia Santonica*, or Tartarian southernwood. They are of two kinds; one called the Aleppo, Alexandria, or Levant wormseed, the other Barbary wormseed.

The former are supposed to be the product of the *Artemisia Contra*, which grows in Persia, Asia Minor, and other parts of the East. They are in fact not the seeds, but the small globular unexpanded flowers of the plant, mixed with their broken peduncles, and with minute, obtuse, smooth leaves. They have a greenish colour, a very strong aromatic odour increased by friction, and a very bitter disagreeable taste.

The Barbary wormseed are thought by some to be derived from the *Artemisia Judaica*, by others from the *A. glomerata* of Sieber, both of which grow in Palestine and Arabia. They consist of broken peduncles, having the calyx sometimes attached to their extremity. The calyx is also sometimes separate, consisting of very small linear obtuse leaflets. The flowers are wanting, or in the shape of minute globular buds. All these parts are covered with a whitish down, which serves to distinguish this variety from the wormseed of the Levant. They are moreover lighter and more coloured than the latter. Their smell and taste are the same.

These products contain a volatile oil and a resinous extractive matter, to which their virtues have been ascribed. A peculiar principle has also been discovered in them, which has received the name of *santonin*, and which is asserted to have decided anthelmintic virtues. It is crystallizable, colourless, tasteless, inodorous, soluble in ether and alcohol, and nearly insoluble in water. It may be obtained by treating wormseed with hydrate of lime and alcohol, evaporating the tincture to one-quarter, filtering the residue to separate the resin, and treating it while hot with concentrated acetic acid. The santonin is deposited in crystals as the liquor cools. In the dose of three or four grains twice a day, it is said to have been found useful as a vermifuge. In larger doses it occasions abdominal pains, and eructations attended with a decided taste of the wormseed. (*Journ. de Pharm.* xvii. 115, and xx. 44.)

Medical Properties and Uses. The products above described have long been celebrated as a vermifuge, and the title of *semen contra*, by which they are designated in many works on pharmacy, originated in their anthelmintic property. They may be given in powder or infusion. The dose in substance is from ten to thirty grains, which should be repeated morning and evening for several days, and then followed by a brisk cathartic. They are not used in this country, having been superseded by the seeds of the *Chenopodium anthelminticum*, which are universally known among us by the name of wormseed. W.

ARUM. *U.S. Secondary.*

Dragon-root.

"Arum triphyllum. Radix. *The root.*" *U.S.*

ARUM. *Sex. Syst.* Monœcia Polyandria.—*Nat. Ord.* Aroideæ.

Gen. Ch. Spathe one-leafed, cowled. *Spadix* naked above, female below, stamineous in the middle. *Willd.*

The root of the *Arum maculatum* is occasionally used as a medicine in Europe, and held a place in the Dublin Pharmacopœia previously to the last edition. Its medicinal properties are so precisely those of the *A. triphyllum* of this country, that the substitution of the latter in our Pharmacopœia was a matter of obvious propriety, independently of the consideration that the root is efficient only in the recent state.

Arum triphyllum. Willd. *Sp. Plant.* iv. 480; Bigelow, *Am. Med. Bot.* i. 52. The *dragon-root*, *Indian turnip*, or *wake-robin*, as this plant is variously called in common language, has a perennial tuberous root, which, early in the spring, sends up a large, ovate, acuminate, variously coloured spathe, convoluted at bottom, flattened and bent over at top like a hood, and supported by an erect, round, green or purplish scape. Within the spathe is a club-shaped spadix, green, purple, black, or variegated, rounded at the end, and contracted near the base, where it is surrounded by the stamens or germs in the diœcious plants, and by both in the monœcious, the female organs being below the male. The spathe and upper portion of the spadix gradually decay, while the germs are converted into a compact bunch of shining, scarlet berries. The leaves, which are usually one or two in number, and stand on long sheathing footstalks, are composed of three ovate acuminate leaflets, paler on their under than their upper surface, and becoming glaucous as the plant advances. There are three varieties of this species of Arum, distinguished by the colour of the spathe, which in one is green, in another dark purple, and in a third white.

The plant is a native of North and South America, and is common in all parts of the United States, growing in damp woods, in swamps, along ditches, and in other moist shady places. All parts of it are highly acrid, but the root only is officinal.

This is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state, it has a peculiar odour, and is violently acrid, producing, when chewed, an insupportable burning and biting sensation in the mouth and throat, which continues for a long time, and leaves an unpleasant soreness behind. According to Dr. Bigelow, its action does not readily extend through the cuticle, as the bruised root may lie upon the skin till it becomes dry, without producing pain or redness. The acrid principle is extremely volatile, and is entirely driven off by heat. It is not imparted to water, alcohol, ether, or olive oil. By exposing the bruised root and stalks to a boiling heat under water, Dr. Bigelow obtained small quantities of an inflammable gas. The root loses nearly all its acrimony by drying, and in a short time becomes quite inert. It contains a large proportion of starch, which may be obtained from it as white and delicate as from the potato. In Europe, the dried root of the *A. maculatum* is said sometimes to be employed by the country people, in times of great scarcity, as a substitute for bread. For medicinal use, the Indian turnip may be preserved fresh for a year, if buried in sand. (*Thatcher.*)

Medical Properties and Uses. Arum in its recent state is a powerful local irritant, possessing the property of stimulating the secretions, particularly those of the skin and lungs. It has been advantageously given in asthma, pertussis, chronic catarrh, chronic rheumatism, and various affections connected with a cachectic state of the system. As immediately taken from the ground, it is too acrid for use. The recently dried root, which retains a portion of the acrimony, but not sufficient to prevent its convenient administration, is usually preferred. It may be given in the dose of ten grains, mixed with gum arabic, sugar, and water, in the form of emulsion, repeated two or three times a day, and gradually increased to half a drachm or more. The powder made into a paste with honey or syrup, and placed in small quantities upon the tongue, so as to be gradually diffused over the mouth and throat, is said to have proved useful in the aphthous sore-mouth of children. ASARI FOLIA. *Lond.*

Asarabacca Leaves.

"Asarum Europæum. *Folia.*" *Lond.*

Off. Syn. ASARI EUROPÆI FOLIA. *Ed.;* ASARUM EUROPÆUM. Folia. *Dub.*

Asaret, Cabaret, *Fr.;* Haselwurzel, *Germ.;* Asaro, *Ital., Span.*

Asarum. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Aristolochiæ.

Gen. Ch. Calyx three or four-cleft, sitting on the germen. *Corolla* none. *Capsule* coriaceous, crowned. *Willd.*

Asarum Europæum. Willd. *Sp. Plant.* ii. 838; Woodv. *Med. Bot.* p. 170. t. 66. The *asarabacca* has a perennial root, with a very short, round, simple, herbaceous, pubescent stem, which in general supports only two leaves and one flower. The leaves, which are opposite and stand on long footstalks, are kidney-shaped, entire, somewhat hairy, and of a shining deep green colour. The flower is large, of a dusky purple colour, and placed upon a short terminal peduncle. The calyx, which supplies the place of a corolla, is bell-shaped, greenish at the base, and divided at the mouth into three pointed purplish segments, which are erect, and turned inwards at their extremity. The filaments are twelve, and prolonged beyond the anthers into a small hook. The style is surmounted by a six-parted reddish stigma. The fruit is a six-celled coriaceous capsule, crowned with the persistent calyx.

This species of Asarum is a native of Europe, growing between 60° and

37° N. latitude, in woods and shady places, and flowering in May. All parts of the plant are acrid. The root and leaves are officinal on the continent of Europe; the leaves only in Great Britain. The root is about as thick as a goose-quill, of a grayish colour, quadrangular, knotted and twisted, and sometimes furnished with radicles at each joint. It has a smell analogous to that of pepper, an acrid taste, and affords a grayish powder. The leaves are nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. Their powder is yellowish-green. Both parts rapidly lose their activity by keeping, and ultimately become inert. Geiger, however, asserts that they keep well if perfectly dry. Their virtues are imparted to alcohol and water, but are dissipated by decoction. According to MM. Feneulle and Lassaigne, the root contains a concrete volatile oil, a very acrid fixed oil, a yellow substance analogous to *cytisin*, starch, albumen, mucilage, citric acid, and saline matters.

Medical Properties and Uses. The root and leaves of asarabacca, either fresh or carefully dried, are powerfully emetic and cathartic, and were formerly much used in Europe with a view to these effects. The dose is from thirty grains to a drachm. But as an emetic they have been entirely superseded by ipecacuanha, and are now used chiefly, if not exclusively, as an errhine. The powdered root, snuffed up the nostrils in the quantity of one or two grains, produces much irritation, and a copious flow of mucus which is said to continue sometimes for several days. The leaves are milder and generally preferred. They should be used in the quantity of three or four grains, repeated every night until the desired effect is experienced. They have been strongly recommended in headach, chronic ophthalmia, and rheumatic and paralytic affections of the face, mouth, and throat.

* * *

ASARUM. *U. S. Secondary.*

Canada Snakeroot. Wild Ginger.

"Asarum Canadense. Radix. *The root.*" *U.S.*

Asarum. See ASARI FOLIA.

Asarum Canadense. Willd. *Sp. Plant.* ii. 838; Bigelow, *Am. Med. Bot.* i. 149; Barton, *Med. Bot.* ii. 85. This species of Asarum very closely resembles the *A. Europæum* or asarabacca in appearance and botanical character. It has a long, creeping, jointed, fleshy, yellowish root, furnished with radicles of a similar colour. The stem is very short, dividing before it emerges from the ground, into two long round hairy leaf-stalks, each of which bears a broad kidney-shaped leaf, pubescent on both surfaces, of a rich shining light green above, veined and pale or bluish beneath. A single flower stands in the fork of the stem, upon a hairy pendulous peduncle. The flower is often concealed by the loose soil or decayed vegetable matter; so that the leaves with their petioles are the only parts that appear above the surface of the ground. There is no corolla. The calyx is very woolly, and divided into three broad concave acuminate segments, with the ends reflexed, of a deep brownish-purple colour on the inside, and of a dull purple inclining to greenish externally. The filaments, which are twelve in number, and of unequal length, stand upon the germ, and rise with a slender point above the anthers attached to them. Near the divisions of the calyx, are three filamentous bodies, which may be considered as nectaries. The pistil consists of a somewhat hexagonal germ, and a conical grooved style, surmounted by six revolute stigmas. The capsule is six-celled, coriaceous, and crowned with the adhering calyx.

The Canada snakeroot, or wild ginger, is an indigenous plant, inhabiting woods and shady places from Canada to Carolina. Its flowering period is from April to July. All parts of the plant have a grateful aromatic odour, which is most powerful in the root. This is the officinal portion.

As we have seen it in the shops, it is in long, more or less contorted pieces, of a thickness from that of a straw to that of a goose-quill, brownish and wrinkled externally, whitish within, hard and brittle, and frequently furnished with short fibres. Its taste is agreeably aromatic and slightly bitter, said to be intermediate between that of ginger and serpentaria, but in our opinion bearing a closer resemblance to that of cardamom. The taste of the petioles, which usually accompany the root, is more bitter and less aromatic.

Among its constituents, according to Dr. Bigelow, are a light-coloured, pungent, and fragrant essential oil, a reddish bitter resinous matter, starch, and gum. It imparts its virtues to alcohol, and less perfectly to water.

Medical Properties and Uses. The root is an aromatic stimulant tonic, with diaphoretic properties, applicable to similar cases with the serpentaria, which it resembles in its effects. It is said to be sometimes used by the country people as a substitute for ginger. From the close botanical analogy of the plant with the European Asarum, it might be supposed, like that, to possess emetic and cathartic properties; but such does not appear to be the case, at least with the dried root. It would form an elegant adjuvant to tonic infusions and decoctions. It may be given in powder or tincture. The dose in substance is twenty or thirty grains. W.

◆

ASCLEPIAS INCARNATA. *U. S. Secondary.*

Flesh-coloured Asclepias.

" Asclepias incarnata. Radix. *The root.*" *U.S.*

ASCLEPIAS. See ASCLEPIAS TUBEROSA.

Asclepias incarnata. Willd. *Sp. Plant.* i. 1267. This species has an erect downy stem, branched above, two or three feet high, and furnished with opposite, nearly sessile, lanceolate, somewhat downy leaves. The flowers are red, sweet-scented, and disposed in numerous crowded erect umbels, which are generally in pairs. The nectary is entire, with its horn exserted. In one variety the flowers are white.

The plant grows in all parts of the United States, preferring a wet soil, and flowering from June to August. Upon being wounded it emits a milky juice. The root is the officinal portion. Its properties are probably similar to those of the *A. Syriaca;* but they have not, so far as we know, been fully tested. Dr. Griffith states that it has been employed by several physicians, who speak of it as a useful emetic and cathartic. (*Journ. of the Phil. Col. of Pharm.* iv. 283.) W.

ASCLEPIAS SYRIACA. *U.S. Secondary.*

Common Silk-weed.

"Asclepias Syriaca. Radix. *The root.*" *U.S.*

ASCLEPIAS. See ASCLEPIAS TUBEROSA.

A. Syriaca. Willd. *Sp. Plant.* i. 1265. The silk-weed has simple stems, from three to five feet high, with opposite, lanceolate-oblong, petiolate leaves, downy on their under surface. The flowers are large, of a pale purple colour, sweet-scented, and arranged in nodding umbels, which are two or three in number. The nectary is bidentate. The pod or follicle is covered with sharp prickles, and contains a large quantity of silky seed-down, which has been sometimes used as a substitute for fur in the manufacture of hats, and for feathers in beds and pillows.

This species of Asclepias is very common in the United States, growing in sandy fields, on the road sides, and on the banks of streams from New England to Virginia. It flowers in July and August. Like the preceding species, it gives out a white juice when wounded, and has hence received the name of *milk-weed*, by which it is frequently called.

Dr. Richardson of Massachusetts found the root possessed of anodyne properties. He gave it with advantage to an asthmatic patient, and in a case of typhous fever attended with catarrh. In both instances it appeared to promote expectoration, and to relieve pain, cough, and dyspnœa. He gave a drachm of the powdered bark of the root, in divided doses, during the day; and employed it also in strong infusion. W.

ASCLEPIAS TUBEROSA. *U.S. Secondary.*

Butterfly-weed.

"Asclepias tuberosa. Radix. *The root.*" *U.S.*

ASCLEPIAS. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Asclepiadeæ.

Gen. Ch. *Calyx* small, five-parted. *Corolla* rotate, five-parted, mostly reflexed. *Staminal crown* (or nectary) simple, five-leaved; leaflets opposite the anthers, with a subulate averted process at the base. *Stigmas* with the five angles (corpuscles) opening by longitudinal chinks. *Pollinia* five distinct pairs. *Torrey.*

Asclepias tuberosa. Willd. *Sp. Plant.* i. 1273; Bigelow, *Am. Med. Bot.* ii. 59; Barton, *Med. Bot.* i. 239. The root of the *butterfly-weed* or *pleurisy-root* is perennial, and gives origin to numerous stems, which are erect, ascending, or procumbent, round, hairy, of a green or reddish colour, branching at the top, and about three feet in height. The leaves are scattered, oblong-lanceolate, very hairy, of a deep rich green colour on their upper surface, paler beneath, and supported usually on short footstalks. They differ, however, somewhat in shape according to the variety of the plant. In the variety with decumbent stems, they are almost linear, and in another variety cordate. The flowers are of a beautiful reddish-orange colour, and disposed in terminal or lateral corymbose umbels. The fruit is an erect lanceolate follicle, with flat ovate seeds connected to a longitudinal receptacle by long silky hairs.

This plant differs from other species of Asclepias in not emitting a milky juice when wounded. It is indigenous, growing throughout the United States from Massachusetts to Georgia, and when in full bloom in the months of June and July, exhibiting a splendid appearance. It is most abundant in the Southern States. The root is the only part used in medicine.

This is large, irregularly tuberous, branching, often somewhat fusiform, fleshy, externally brown, internally white and striated, and in the recent state of a sub-acrid nauseous taste. When dried it is easily pulverized, and has a bitter but not otherwise unpleasant taste. It yields it virtues readily to boiling water.

Medical Properties and Uses. The root of the Asclepias tuberosa is diaphoretic and expectorant, without being stimulant. In large doses it is often also cathartic. In the Southern States it has long been employed by regular practitioners in catarrh, pneumonia, pleurisy, consumption, and other pectoral affections; and appears to be decidedly useful if applied in the early stages, or, after sufficient depletion, when the complaint is already formed. Its popular name of *pleurisy-root* expresses the estimation in which it is held as a remedy in this disease. It has also been used advantageously in acute rheumatism, and might probably prove beneficial in our autumnal remittents. Dr. Eberle found it highly useful in dysentery. (*Eberle's Practice*, i. 216.) Much testimony might be advanced in proof of its possessing very considerable diaphoretic powers. It is said also to be gently tonic, and has been popularly employed in pains of the stomach arising from flatulence and indigestion.

From twenty grains to a drachm of the root in powder may be given several times a day; but as a diaphoretic it is best administered in decoction or infusion, made in the proportion of an ounce to the quart of water, and given in the dose of a teacupful every two or three hours till it operates. W.

ASSAFŒTIDA. *U. S.*

Assafetida.

"Ferula assafœtida. Succus radicis concretus. *The concrete juice of the root.*" *U.S.*

Off. Syn. ASSAFŒTIDÆ GUMMI-RESINA. Ferula Assafœtida. Gummi-resina. *Lond.;* FERULÆ ASSÆFŒTIDÆ GUMMI-RESINA. *Ed.;* ASSAFŒTIDA. FERULA ASSAFŒTIDA. Gummi Resina. *Dub.*

Assafœtida, *Fr.;* Stinkasant, Teufelsdreck, *Germ.;* Assafetida, *Ital.;* Asafetida, *Span.;* Ungoozeh, *Persian;* Hilteet, *Arab.*

FERULA. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Fruit* oval, compressed plane, with three streaks on each side. *Willd.*

Ferula Assafœtida. Willd. *Sp. Plant.* i. 1413; Kœmpfer, *Amœnitat. Exotic.* 535. t. 536. The following description of the plant which yields assafetida is derived from that by Kœmpfer who wrote from actual observation. The root is perennial, fleshy, tapering, when of full size as large as a man's leg, beset with many strong fibres near the top, externally blackish, internally white, and abounding in an excessively fetid, opaque, milky juice. The leaves, all of which spring immediately from the root, are six or seven in number, nearly two feet long, bipinnate, with the leaflets alternate, smooth, variously sinuated and lobed, sometimes lanceolate, of a deep green colour and fetid smell. From the midst of the leaves rises a luxuriant, herbaceous stem, from six to nine feet in height, two inches in diameter at the base, simple, erect, round, smooth, striated, and terminating in large plano-convex umbels with numerous radii. The flowers are pale yellow; the seeds oval, flat, foliaceous, and of a reddish-brown colour. The plant is said to differ greatly both in the shape of its leaves, and the character of its fetid product, according to the situation and soil in which it grows.

It is a native of Persia and perhaps other countries of the East; and flourishes most abundantly in the mountainous provinces of Laar and Chorassan, where its juice is collected. Burns, in his travels into Bokhara, states that the plant is eaten with relish by the people, and that sheep crop it greedily. Some suppose that other species of Ferula contribute to the production of the assafetida of commerce.

The oldest plants are most productive, and those under four years old are not considered worth cutting. At the season when the leaves begin to fade, the earth is removed from about the top of the root, and the leaves and stem being twisted off near their base, are thrown with other vegetable matters over the root, in order to protect it from the sun. After some time the summit of the root is cut off transversely, and the juice which exudes having been scraped off, another thin slice is removed, in order to present a fresh surface for exudation. This process is repeated at intervals till the root ceases to afford juice, and perishes. During the whole period of collection, which occupies nearly six weeks, the solar heat is as much as possible excluded. The juice collected from numerous plants is put together, and allowed to harden in the sun.

Assafetida is brought to this country either from India, whither it is conveyed from Bushire, or by the route of Great Britain. It usually comes in mats or cases, the former containing eighty or ninety, the latter from two hundred to four hundred pounds. It is sometimes also imported in casks.

As found in the shops it is in irregular masses, of a softish consistence when not long exposed, of a yellowish or reddish-brown colour externally, exhibiting when broken an irregular whitish, somewhat shining surface, which soon becomes red on exposure to the air, and ultimately passes into a dull yellowish-brown. This change of colour is characteristic of assafetida. The masses appear as if composed of distinct portions intermingled and agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the tears are brought in a separate state. The odour of assafetida is alliaceous, extremely fetid, and tenacious; the taste, bitter, acrid, and durable. The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its smell and taste, particularly the former. Kœmpfer assures us that one drachm of the fresh juice diffuses a more powerful odour through a close room than one hundred pounds of the drug as usually kept in the stores. Assafetida softens by heat without melting, and is of difficult pulverization. Its sp. gr. is 1.327. (*Berzelius.*) It is inflammable, burning with a clear, lively flame. It yields all its virtues to alcohol, and forms a clear tincture, which becomes milky on the addition of water. Macerated in water it produces a turbid red solution, and triturated with that fluid gives a white or pink-coloured milky emulsion of considerable permanence. In one hundred parts, Pelletier found 65 parts of resin, 19.44 of gum, 11.66 of bassorin, 3.60 of volatile oil, with traces of supermalate of lime. Brandes, the German chemist, obtained 4.6 parts of volatile oil, 47.25 of a bitter resin soluble in ether, 1.6 of a tasteless resin insoluble in ether, 1.0 of extractive, 19.4 of gum containing traces of potassa and lime united with sulphuric, phosphoric, acetic, and malic acids, 6.4 of bassorin, 6.2 of sulphate of lime, 3.5 of carbonate of lime, 0.4 of oxide of iron and alumina, 0.4 of malate of lime with resin, 6.0 of water, and 4.6 of impurities consisting chiefly of sand and woody fibre. The odour of the gum-resin depends on the *volatile oil*, which may be obtained separate by distillation with water or alcohol. It is lighter than water, colourless when first distilled, but becoming yellow with age, of an exceedingly offensive odour, and of a taste at first flat, but afterwards bitter and acrid. It is said to contain a small portion of sulphur. The volatile oil and the bitter resin are the active principles.

Medical Properties and Uses. The effects of assafetida on the system are those of a moderate stimulant, powerful antispasmodic, efficient expectorant, and feeble laxative. As an antispasmodic simply, it is employed in the treatment of hysteria, hypochondriasis, convulsions of various kinds, spasm of the stomach and bowels unconnected with inflammation, and in those numerous irregular nervous disorders which accompany derangement of the different organs, or result from mere debility of the nervous system. From the union of expectorant with antispasmodic powers, it is highly useful in spasmodic pectoral affections, such as hooping-cough, asthma, and certain infantile coughs and catarrhs, complicated with disorder of the nervous apparatus, or with a disposition of the system to sink. In these last cases it has been employed with great success by Dr. Jos. Parrish of Philadelphia.* In catarrhus senilis; the secondary stages of peripneumonia notha, croup, measles, and catarrh; in pulmonary consumption; in fact, in all cases of disease of the chest in which the lungs do not perform their office from want of due nervous energy, and in which inflammation is absent or has been sufficiently subdued, assafetida may occasionally be prescribed with advantage. In the form of enema it may be beneficially employed in typhoid diseases attended with inordinate accumulation of air in the bowels, and in other cases of tympanitic abdomen. The same form will be found most convenient in the hysteric paroxysm, and other kinds of convulsion. In most cases its laxative tendency adds to its advantages; but in some instances must be counteracted by the addition of laudanum. It may often be usefully combined with purgative medicines in constipation of the bowels with flatulence.

It appears to have been known in the East from very early ages; and notwithstanding its repulsive odour, is at present much used in India and Persia as a condiment. Persons soon habituate themselves to its smell, which they even learn to associate pleasantly with the agreeable effects experienced from its internal use. Children with the hooping-cough sometimes become fond of it; and older persons may be found without going so far as India, who employ it habitually.

The medium dose is ten grains, which may be given in pill or emulsion. (See *Mistura Assafœtidæ.*) The tincture is officinal, and is frequently used. When given by injection it should be prepared by trituration with warm water. From half a drachm to two drachms may be administered at once in this way. As assafetida is not apt to affect the brain injuriously, it may be given very freely when not contra-indicated by the existence of inflammatory action.

CITRUS. *Sex. Syst.* Polyadelphia Icosandria.—*Nat. Ord.* Aurantiaceæ.

Gen. Ch. Calyx five-cleft. *Petals* five, oblong. *Anthers* twenty, the filaments united into different parcels. *Berry* nine-celled. *Willd.*

This very interesting genus is composed of small evergreen trees, with ovate, or oval-lanceolate, and shining leaves, odoriferous flowers, and fruits which usually combine beauty of colour with a fragrant odour and a grateful taste. They are all natives of warm climates, and where the winters are severe require the aid of artificial heat. Though the species are not numerous, great diversity exists in the character of the fruit; and many varieties, founded upon this circumstance, are noticed by writers. In the splendid work on the natural history of the *Citrus* by Risso and Poiteau, 169 varieties are described under the eight following heads:—1. sweet oranges, 2. bitter and sour oranges, 3. bergamots, 4. limes, 5. shaddocks, 6. lumes, 7. lemons, and 8. citrons. Of these it is difficult to decide which have just claims to the rank of distinct species, and which must be considered merely as varieties. Those employed in medicine may be arranged in two sets, of which the orange, *C. Aurantium*, and the lemon, *C. Medica*, are respectively the types, the former characterized by a winged, the latter by a naked or nearly naked petiole. The form and character of the fruit which are not entirely constant, serve as the basis of the subdivisions. The *C. decumana*, which yields the shaddock, agrees with the *C. Aurantium* in the form of its petiole; but its fruit is not officinal.

Citrus Aurantium. Willd. *Sp. Plant.* iii. 1427; Woodv. *Med. Bot.* p. 523, t. 188. The orange tree grows to the height of about fifteen feet. Its stem is round, very much branched, sometimes even from the base, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green colour. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with essential oil; and when rubbed between the fingers, are highly fragrant. Their footstalks are about an inch long, and are furnished with wings or lateral appendages. The flowers, which have a delightful odour, are large, white, and attached by short peduncles, singly or in clusters, to the smaller branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct portions, and support yellow anthers. The germen is roundish, and bears a cylindrical style, which is terminated by a globular stigma. The fruit is a spherical berry, often somewhat flattened at its base and apex, rough, of a yellow or orange colour, and divided internally into nine vertical cells, in each of which are from two to four seeds, surrounded by a pulpy matter. The rind of the fruit is double, consisting of a thin exterior layer which abounds in vesicles filled with a fragrant essential oil, and of an interior one which is thick, white, fungous, insipid, and inodorous. There are two varieties of the *C. Aurantium*, considered by some as distinct species. They differ only in the character of the fruit, which in one is sweet, in the other sour and bitterish. The first retains the original botanical title, the second is called *Citrus vulgaris* by Risso and others. The Seville orange is the product of the latter.

This beautiful evergreen, in which the fruit is mingled, in every stage of its growth, with the blossoms and foliage, is one of those productions of the tropics which have been applied to the most numerous purposes both of utility and ornament. A native of China and India, it was introduced into Europe at a very early period, was transplanted to America soon after the first settlement of this continent, and is now found in every civilized country where the climate is favourable to its cultivation. In colder countries, it is one of the most cherished ornaments of the hot-house, though in this situation its beauties are not fully developed, and its fruit does not attain perfection. It flourishes in the most southern portion of our own country, particularly in the neighbourhood of St. Augustine in Florida, whence we annually derive a considerable supply of very fine oranges. The tree also grows in the gardens about New Orleans, but is sometimes destroyed by the frosty winters which are incident to that climate. The fruit is brought to us chiefly from the South of Europe and the West Indies. The Havana oranges have the sweetest and most pleasant flavour.

Various parts of the orange-tree are used in medicine. The leaves, which are bitter and aromatic, are employed in some places in the state of infusion as a gently incitant diaphoretic. The fresh flowers impart to water distilled from them their peculiar fragrance; and the preparation thus obtained is much esteemed in the South of Europe for its antispasmodic virtues. The distilled water of orange-flowers is recognised as officinal by the Dublin College. An oil is also obtained from the flowers by distillation, which is called *neroli* in France, and is much used in perfumery, and in the composition of *liqueurs*. It is an ingredient of the famous Cologne water. The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning lathe, are sometimes employed to maintain the discharge from issues. They are preferred to peas on account of their agreeable odour, and by some are thought to swell less with the moisture; but this is denied by others, and it is asserted that they require to be renewed at the end of twenty-four hours. An essential oil is obtained from them by distillation, known to the French by the name of *essence de petit grain*, and employed for similar purposes with that of the flowers. The unripe fruit is also among the Dublin officinals. All the British Colleges recognise the ripe fruit or its juice. The London directs the Seville orange. The juice of this variety is sour and bitterish, and forms with water a refreshing and grateful drink in febrile diseases. It is employed for the same purposes with the juice of the lemon, which it resembles in containing citric acid, though in much smaller proportion. The sweet orange is much more pleasant to the taste, and is very extensively used as a light refrigerant article of diet in inflammatory diseases, care being taken to reject the membranous portion, and to swallow only the pulp. The rind of the mature fruit is the only part directed by the U.S. Pharmacopœia. The outer portion is that considered officinal, as the inner is wholly destitute of useful properties, and by its affinity for moisture produces a disposition in the peel to become mouldy. The best mode of separating the outer rind, when its desiccation and preservation are desired, is to pare it from the orange in narrow strips with a sharp knife, exactly as we pare an apple. When the object is to apply the fresh rind to certain pharmaceutic purposes, as, for instance, to the preparation of the *confection of orange peel*, it is best separated by a grater. The dried peel, sold in our drug stores, is usually that of the Seville orange, and is chiefly brought from the Mediterranean.

Properties. Orange peel has a grateful aromatic odour, and a warm bitter taste, which depend upon the essential oil contained in its vesicles. The rind of the Seville orange is much more bitter than that of the other variety. Both yield their sensible properties to water and alcohol. The essential oil may be obtained by simple expression from the fresh grated rind. It has properties closely resembling those of the oil of lemons, and may be used for similar purposes.

Medical Properties and Uses. Orange peel is a mild tonic, carminative, and stomachic, but is seldom used alone. It is chiefly employed to communicate a pleasant flavour to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. It is a frequent and very useful addition to bitter infusions and decoctions, as those of gentian, quassia, columbo, and especially Peruvian bark. It is obviously improper to subject orange peel to long boiling, as the essential oil on which its virtues chiefly depend is thus driven off. The dose in substance is from half a drachm to a drachm three times a day. Large quantities are sometimes productive of mischief, especially in children, in whom violent colic, and even convulsions, are sometimes induced by it. We have known the case of a child, in which death resulted from eating the rind of an orange.

When the object in the use of orange peel is simply to obtain its agreeable flavour, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

AVENÆ FARINA. *U.S.*

Oatmeal.

"Avena sativa. Farina. *The meal.*" *U.S.*

Off. Syn. AVENÆ SEMINA. Avena sativa. Semina tunicis nudata. *Lond.;* AVENÆ SATIVÆ SEMINA. Semina decorticata. AVENÆ SATIVÆ FARINA. Ex seminibus. *Ed.;* AVENA SATIVA. Farina ex seminibus. *Dub.*

Farine d'avoine, *Fr.;* Hafermehl, *Germ.;* Farina dell'avena. *Ital.;* Harina de avena *Span.*

Avena. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Gramineæ.

Gen. Ch. Calyx two-valved, many-flowered, with a twisted awn on the back. *Willd.*

Avena sativa. Willd. *Sp. Plant.* i. 446. The common oat is so well known that a minute description would be superfluous. It is specifically distinguished by its "loose panicle, its two-seeded glumes, and its smooth seeds, one of which is awned." It was known to the ancients, and is now cultivated in all civilized countries; but its original locality has not been satisfactorily ascertained. It grows wild in Sicily, and is said to have been seen by Anson in the Island of Juan Fernandez, on the coast of Chili.

This grain, though cultivated chiefly for horses, is very nourishing, and is largely consumed as food by the inhabitants of Scotland, the North of Ireland, Brittany, and some other countries. The seeds deprived of their husk are called *groats*, and are directed by the British Colleges; but are not officinal on this side of the Atlantic. It is only the meal, prepared by grinding the seeds, that is kept in our shops.

Oatmeal contains, according to Vogel, in 100 parts, 59 of starch, 4.30 of a grayish substance resembling rather coagulated albumen than gluten, 8.25 of sugar and a bitter principle, 2.50 of gum, 2 of fixed oil, and 23.95 of fibrous matter including loss. It has no smell, is very slightly but not unpleasantly bitter, and yields most of its nutritive matter with facility to boiling water.

Gruel made with oatmeal affords a nutritious, bland, and easily digested aliment, admirably adapted to inflammatory diseases; and from its somewhat laxative tendency, preferable in certain cases to the purely mucilaginous or amylaceous preparations. It is very often administered after brisk cathartics, in order to render them easier and at the same time more efficient in their action. It is sometimes also used in the form of enema; and the meal boiled with water into a thick paste, forms an excellent emollient cataplasm. *Oatmeal gruel* may be prepared by boiling an ounce of the meal with three pints of water to a quart, straining the decoction, allowing it to stand till it cools, and then pouring off the clear liquor from the sediment. Sugar and lemon-juice may be added to improve its flavour; and raisins are not unfrequently boiled with the meal and water for the same purpose.

AZEDARACH. U.S. *Secondary.*

Azedarach.

"Melia azedarach. Radicis cortex. *The bark of the root.*" *U.S.*

MELIA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Meliaceæ.

Gen. Ch. *Calyx* five-toothed. *Petals* five. *Nectary* cylindrical, toothed, bearing the *anthers* in the throat. *Drupe* with a five-celled nut. *Willd.*

Melia Azedarach. Willd. *Sp. Plant.* ii. 558; Michaux, *N. Am. Sylv.* iii. 4. This is a beautiful tree, rising thirty or forty feet in height, with a trunk fifteen or twenty inches in diameter. When standing alone, it attains less elevation, and spreads itself out into a capacious summit. Its leaves are large, and doubly pinnate, consisting of smooth, acuminate, denticulate, dark green leaflets, which are disposed in pairs with an odd one at the end. The flowers, which are of a lilac colour and delightfully fragrant, are disposed in beautiful axillary clusters near the extremities of the branches. The fruit is a round drupe, which, when ripe, is about as large as a cherry, and of a yellowish colour.

This species of Melia is variously called *pride of India*, *pride of China*, and *common bead tree*. It is a native of Syria, Persia, and the North of India, and is cultivated for ornamental purposes in various parts of the eastern and western continents. It is abundant in our Southern States, where it lines the streets of cities, and adorns the environs of dwellings, and in some places has become naturalized. North of Virginia it does not flourish, though small trees may sometimes be seen in sheltered situations. Its flowers appear early in the spring. The fruit is sweetish to the taste, and, though said by some to be poisonous, is eaten by children at the South without inconvenience, and is even reputed to be powerfully vermifuge. But the bark of the root is the part chiefly employed. It is preferred in the recent state, and is therefore scarcely to be found in the shops at the North. It has a bitter nauseous taste, and yields its virtues to boiling water.

Medical Properties and Uses. This bark is cathartic and emetic, and in large doses is said to produce narcotic effects similar to those of Spigelia, especially if gathered at the season when the sap is mounting. It is considered in the Southern States an efficient anthelmintic, and appears to enjoy, in some places, an equal degree of confidence with the pink-root. It is thought also to be useful in those infantile remittents which resemble verminose fevers, without being dependent on the presence of worms. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the dose for a child is half a fluidounce every two or three hours, till it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. W.

BARYTA.

Baryta.

Baryte, *Fr.;* Baryt, Baryterde, Schwererde, *Germ.;* Barite, *Ital.;* Barito, Tierra pesada, *Span.*

This earth is not used in medicine in its uncombined state; but as several of its salts are officinal, a short notice of it may be proper.

Baryta exists in nature almost exclusively as a carbonate and sulphate. It may be obtained from the carbonate by violent ignition with carbonaceous matter, whereby the carbonic acid is decomposed and dissipated; and from the sulphate, by ignition with charcoal which converts it into a sulphuret, subsequent solution in nitric acid, and strong ignition of the nitrate formed to dissipate the acid.

Baryta, obtained by either of these processes, is anhydrous, and of a grayish-white colour. It is very refractory, requiring the flame of the compound blow-pipe for fusion. When sprinkled with water it becomes hot, and, after the lapse of some time, is reduced to the state of a fine white powder. By the addition of more water it becomes a hard, crystalline mass. In close vessels it dissolves in boiling water, forming the test called barytic water; and the solution thus obtained will yield, by proper concentration, crystals of baryta, containing a large quantity of water of crystallization.

Hydrate of baryta has an acrid, caustic, alkaline taste. It acts on the animal economy as a poison. Its sp. gr. is about 4. Exposed to a high temperature, it melts in its water of crystallization, then becomes dry, and remains in the form of powder. At a still higher temperature, it undergoes the igneous fusion and flows like oil. In this state, if poured out on a cold surface, it forms a solid of a crystalline aspect, which still retains one equivalent of water.

Baryta is the protoxide of a metal called barium, and consists of one equivalent of barium 68.7, and one equiv. of oxygen 8=76.7. *Turner, fifth Edit.*

The only preparation of baryta used in medicine is the muriate, to obtain which either the native carbonate or sulphate may be employed. These minerals are noticed in the two succeeding articles. B.

◆

BARYTÆ CARBONAS. *U.S.*

Carbonate of Baryta.

Off. Syn. CARBONAS BARYTÆ. *Ed.*

Carbonate de baryte, *Fr.;* Kohlensaurer Baryt, *Germ.;* Barite carbonata, *Ital.;* Carbonato de barito, *Span.*

The officinal carbonate of baryta is the native carbonate, a mineral discovered in 1783 at Anglesark in England, by Dr. Withering, in honour of whom it is sometimes called *Witherite.* It is rather a rare mineral. It is found principally in Sweden, Scotland, and England; but most abundantly in Anglesark, in Lancashire. It has not been met with in the United States. It was, indeed, announced, in Silliman's Journ. vol. ii. as occurring near Lexington, Ky., but this statement has not been confirmed. It occurs usually in small fibrous masses, but sometimes crystallized. Its sp. gr. varies from 4.2 to 4.4. Generally it is strongly translucent, but sometimes opaque. Its colour is whitish or gray, usually tinged with yellow or green, and occasionally with blue, brown, and red. It effervesces with acids, and before the blow-pipe, melts into a white enamel without losing its carbonic acid. It is distinguished from the carbonate of strontia, with which it is most liable to be confounded, by its greater specific gravity, and by the absence of a reddish flame upon burning alcohol impregnated with its nitric solution. On the animal economy, it acts as a poison. It consists of one equivalent of acid 22.12, and one of base 76.7=98.82. Its only officinal use is to obtain the muriate of baryta. (See *Barytæ Murias.*) The London College has no barytic preparations. B.

◆

BARYTÆ SULPHAS. *Dub.*

Sulphate of Baryta.

Off. Syn. SULPHAS BARYTÆ. *Ed.*

Ponderous spar, Baroselenite; Sulfate de baryte, *Fr.;* Schwefelsaurer Baryt, *Germ.;* Barite solfata, *Ital.*.

The native sulphate of baryta is used in pharmacy with the same view as the native carbonate; namely, to obtain the muriate. The U. S. Pharmacopœia directs for this purpose the carbonate of baryta, and the Dublin College the sulphate; while the Edinburgh College retains both, giving a separate formula for the use of each, according to the option of the operator. (See *Barytæ Murias.*)

Sulphate of baryta is a heavy mineral, varying in sp. gr. from 4.29 to 4.60. It is generally translucent, sometimes transparent or opaque, and commonly of a white colour, either pure, or with shades of yellow, red, blue, or brown. Its primitive form is a right rhombic prism. Before the blow-pipe, it strongly decrepitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. By this treatment, it is partially converted into sulphuret, and, if applied to the tongue, will give a taste like that of putrid eggs, which arises from the formation of sulphuretted hydrogen. It is distinguished from the sulphate of strontia, by being free from the sulphuretted hydrogen taste after ignition on charcoal; and from the carbonates of baryta and strontia, by not effervescing with dilute nitric acid. This salt, on account of its great insolubility, is not poisonous. It consists of one equivalent of acid 40.1, and one equiv. of baryta 76.7=116.8.

Off. Prep. Barytæ Murias, *Dub.*, *Ed.* B.

◆

BELLADONNA. *U.S.*

Deadly Nightshade.

"Atropa belladonna. Folia. *The leaves.*" *U.S.*

Off. Syn. BELLADONNÆ FOLIA. Atropa Belladonna. Folia. *Lond.;* ATROPÆ BELLADONNÆ FOLIA, *Ed.;* ATROPA BELLADONNA. Folia et radix. *Dub.*

Belladone, *Fr.;* Gemeine Tollkirsche, Wolfskirsche, *Germ.;* Belladonna, *Ital.;* Belladona, Belladama, *Span.*

ATROPA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ.

Gen. Ch. Corolla bell-shaped. *Stamens* distant. *Berry* globular, two-celled. *Willd.*

Atropa Belladonna. Willd. *Sp. Plant.* i. 1017; Woodv. *Med. Bot.* p. 230. t. 82. The deadly nightshade is an herbaceous perennial plant, with a thick and fleshy root, from which rise several erect, round, purplish, branching, annual stems, to the height of about three feet. The leaves, which are attached by short footstalks to the stem, are in pairs of unequal size, oval, pointed, entire, of a dusky green colour on their upper surface, and paler beneath. The flowers are large, bell-shaped, pendent, of a dull reddish colour, and are supported upon solitary peduncles, which rise from the axils of the leaves. The fruit is a roundish berry with a longitudinal furrow on each side, at first green, afterwards red, ultimately of a deep purple colour, bearing considerable resemblance to the cherry, and containing, in two distinct cells, numerous seeds, and a sweetish violet-coloured juice. The calyx adheres to the base of the fruit.

This plant is a native of Europe, where it grows in shady places, along walls, and amidst rubbish, flowering in June and July, and ripening its fruit in September. The leaves are the only part directed by the United States, London, and Edinburgh Pharmacopœias; the root also is ordered by the Dublin College.

Properties. The dried leaves are of a dull greenish colour, with a very faint narcotic odour, and a sweetish subacrid, slightly nauseous taste. The root is long, woody, round, from one to several inches in thickness, branched and fibrous, externally when dried of a reddish-brown colour, internally whitish, and having the same taste with the leaves. Both the leaves and root, as well as all other parts of the plant, impart their active properties to water and alcohol. The juice of belladonna was analyzed by Vauquelin, who discovered in it an azotized substance, insoluble in alcohol, soluble in water, and affording a precipitate with the infusion of galls; and another substance, soluble in alcohol, of a bitter and nauseous taste, and yielding ammonia by destructive distillation. The activity of the plant he considered to reside in the latter. The German chemist, Brandes, obtained more precise results. It appeared from his analysis that the narcotic principle of belladonna was of an alkaline nature; and he supposed it to exist in the plant combined with an excess of malic acid. It was appropriately named *atropia.* Besides the malate of atropia, Mr. Brandes found in the dried herb two azotized principles, a green resin (*chlorophylle*), wax, gum, starch, albumen, lignin, and various saline ingredients. The alkaline principle was afterwards detected by M. Runge; and the fact of its existence has recently been established beyond question by the experiments of Geiger and Hesse, who obtained it from an extract prepared with the stems and leaves of the plant. It was first, however, procured in a state of purity by Mr. Mein, a German apothecary, who extracted it from the root.* *Atropia* crystallizes in white, silky prisms; is inodorous and of a bitter taste; dissolves easily in absolute alcohol and ether, but very slightly in water, and more freely in all these liquids hot than cold; melts at a temperature above 212°, and is volatilized unchanged; restores the colour of litmus paper reddened by the acids; forms soluble salts with the sulphuric, nitric, muriatic, and acetic acids; and, in a very dilute solution, produces, when applied to the eye, a speedy and durable dilatation of the pupil. Like the other vegetable alkalies, it consists of carbon, hydrogen, oxygen, and nitrogen.

Medical Properties and Uses. The action of belladonna is that of a powerful narcotic, possessing also diaphoretic and diuretic properties, and somewhat disposed to operate upon the bowels. Orfila infers from his experiments, and from known facts, that it has little intensity of local action, but is absorbed, and entering the circulation, exercises its influence upon the nervous system, especially upon the brain. Among the first obvious effects which it produces when taken in the usual dose, and continued for some time, are dryness and stricture of the fauces and neighbouring parts, with slight uneasiness or giddiness of the head, and more or less dimness of vision. The practitioner should watch for these effects as signs of the activity of the medicine, and should gradually increase the dose till some one of them is experienced in a slight degree, unless the object at which he aims should be previously attained; but so soon as they occur the dose should be diminished, or the use of the narcotic suspended for a time. When taken in too large a quantity, belladonna is capable of producing the most deleterious effects. It is in fact a powerful poison, and many instances are recorded in which it has been accidentally swallowed or purposely administered with fatal consequences. All parts of the plant are poisonous. It is not uncommon, in countries where the belladonna grows wild, for children to pick and eat the berries, allured by their fine colour and sweet taste. Soon after the poison has been swallowed, its peculiar influence is experienced in dryness of the mouth and fauces, great thirst, difficult deglutition, nausea and ineffectual retching, vertigo, intoxication or delirium attended with violent gestures and sometimes with fits of laughter, and followed by a comatose state. The pupil is dilated and insensible to light, the face red and tumid, the mouth and jaws spasmodically affected, the stomach and bowels insusceptible of impressions, in fact the whole nervous system prostrate and paralyzed. A feeble pulse, cold extremities, subsultus tendinum, deep coma or delirium, and sometimes convulsions, precede the fatal termination. Dissection discloses appearances of inflammation in the stomach and intestines; and it is said that the body soon begins to putrefy, swells, and becomes covered with livid spots, while dark blood flows from the mouth, nose, and ears. To obviate the poisonous effects of belladonna, the most effectual method is to evacuate the stomach as speedily as possible, either by means of emetics, or the stomach-pump, and afterwards to cleanse the bowels by purgatives and enemata. It is not probable that vinegar, which has been recommended, can be of any essential service as an antidote: the infusion of galls might possibly be useful, and, if the experiments of M. Runge can be relied on, lime-water or the alkaline solutions would render the poisonous matter which remained in the stomach inert.

---

* The following is the process employed by Mein. The roots of plants two or three years old were selected. Of these, reduced to an extremely fine powder, 24 parts were digested, for several days, with 60 parts of alcohol of 86 or 90 per cent. The liquid having been separated by strong expression, the residue was treated anew with an equal quantity of alcohol; and the tinctures, poured together and filtered, were mixed with one part of hydrate of lime, and frequently shaken for twenty-four hours. The copious precipitate which now formed was separated by filtering; and diluted sulphuric acid was added drop by drop to the filtered liquor, till slightly in excess. The sulphate of lime having been separated by a new filtration, the alcoholic liquid was distilled to one-half, then mixed with 6 or 8 parts of pure water, and evaporated with a gentle heat till the whole of the alcohol was driven off. The residual liquid was filtered, cautiously evaporated to one-third, and allowed to cool. A concentrated aqueous solution of carbonate of potassa was then gradually added, so long as the liquid continued to be rendered turbid; and the mixture was afterwards suffered to rest some hours. A yellowish resinous substance which opposes the crystallization of the atropia was thus precipitated. From this the liquid was carefully decanted, and a small additional quantity of the solution of the carbonate was dropped into it, till it no longer became turbid. A gelatinous mass now gradually formed, which, at the end of twelve or twenty-four hours, was agitated in order to separate the mother-waters, then thrown upon a filter, and dried by folds of unsized paper. The substance thus obtained, which was atropia in an impure state, was dissolved in five times its weight of alcohol; and the solution, having been filtered, was mixed with six or eight times its bulk of water. The liquor soon became milky, or was rendered so by evaporating the excess of alcohol, and, in the course of twelve or twenty-four hours, deposited the atropia in the form of light yellow crystals, which were rendered entirely pure and colourless by washing with a few drops of water, drying on blotting paper, and again treating with alcohol as before. From twelve ounces of the root, Mein obtained by this process twenty grains of the pure alkali. (*Journ. de Pharm.* xx. 87.)

Notwithstanding the tremendous energy of this narcotic when taken in very large doses, it has been used as a medicine, even from very early times. The leaves were first employed externally to discuss scirrhous tumours, and heal cancerous and other ill-conditioned ulcers; and were afterwards administered internally for the same purpose. Much evidence of their beneficial influence in these affections is on record, and even Dr. Cullen has spoken in their favour; but this application of the remedy has fallen into disuse. It is at present more esteemed in nervous diseases. The German practitioners are much in the habit of using it in hooping-cough, in the advanced stages of which it is undoubtedly sometimes beneficial. In neuralgia it is one of the most effectual remedies in our possession; and we ourselves can bear testimony to its usefulness in this complaint. Hufeland recommends it in the convulsions dependent on scrofulous irritation. It has been prescribed also in chorea, epilepsy, hydrophobia, mania, paralysis, amaurosis, rheumatism, gout, obstinate intermittents, dropsy and jaundice; and in such of these affections as have their seat chiefly in the nervous system, it may sometimes do good. It is said to have been effectually employed in several cases of strangulated hernia. In Germany it has within a few years acquired great credit as a preventive of scarlatina—an application of the remedy first suggested by the famous author of the *homœopathic* doctrine,* and founded upon the idea, that, as the symptoms produced by scarlatina in the nervous system closely resemble those which result from large doses of belladonna, the former might be prevented, or at least moderated, by establishing the latter, as small-pox is prevented by vaccination, or rendered milder if the system has already come partially under its influence.

Applied to the eye, belladonna has the property of dilating the pupil exceedingly, and for this purpose is sometimes employed by European oculists previously to the operation for cataract. In cases of partial opacity of the crystalline lens, confined to the centre of that body, vision is temporarily improved by a similar use of the remedy; and it may also perhaps be beneficially used, when, from inflammation of the iris, there is danger of a permanent closure of the pupil. For these purposes, a strong infusion of the plant, or a solution of the extract, may be dropped into the eye, or a little of the extract itself rubbed upon the eyelids. The same application of the remedy has been recommended in cases of morbid sensibility of the eye. The decoction or extract of belladonna applied to the neck of the uterus, is asserted to have hastened tedious labour dependent on rigidity of the os tincæ.

Belladonna may be given in substance, infusion, or extract. The dose of the powdered leaves is for children from the eighth to the fourth of a grain, for adults one or two grains, repeated daily, or twice a day, and gradually increased till the peculiar effects of the medicine are experienced. An infusion may be prepared by adding a scruple of the dried leaves to ten fluidounces of boiling water, of which from one to two fluidounces is the dose for an adult. The extract is more used in the United States than any other preparation. (See *Extractum Belladonnæ.*) It is by dropping into the eye a strong infusion, or a solution of the extract, that the dilating effect of belladonna upon the pupil is obtained.

BENZOINUM. *U.S.*

Benzoin.

"Styrax benzoin. Succus concretus. *The concrete juice.*" *U.S.*

Off. Syn. BENZOINUM. Styrax Benzoin. Balsamum. *Lond.;* STYRACIS BENZOINI BALSAMUM, *Ed.;* STYRAX BENZOIN. Resina. *Dub.*

Benjoin, *Fr.;* Benzoe, *Germ.;* Belzoino, *Ital.;* Benjui, *Span.*

The botanical source of benzoin was long uncertain. At one time it was generally supposed in Europe to be derived from the *Laurus Benzoin* of this country. This error was corrected by Linnæus, who, however, committed another, in ascribing the drug to the *Croton Benzoë*, a shrub which he afterwards described under the name of *Terminalia Benzoin.* Mr. Dryander was the first who ascertained the true benzoin tree to be a *Styrax;* and his description, published in the 77th vol. of the English Philosoph. Transact., has been copied by most subsequent writers. The specimen by which Mr. Dryander decided the generic character, was obtained by Sir Jos. Banks from Mr. Marsden at Sumatra.

STYRAX. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Guaiacinæ, *Juss.;* Styraceæ, *Richard*, *Lindley.*

Gen.Ch. *Calyx* inferior. *Corolla* funnelshaped. *Drupe* two-seeded. *Willd.*

Styrax Benzoin. Willd. *Sp. Plant.* ii. 623; Woodv. *Med. Bot.* p. 294. t. 102. This is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above and downy beneath. The flowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang all on the same side upon short slender pedicels.

The benzoin, or benjamin tree as it is sometimes called, is a native of Sumatra, Java, Laos, and Siam. (*Ainslie.*) By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure, and constitutes the *benzoin* of commerce. A tree is thought of a proper age to be wounded at six years, when its trunk is about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin. It is exported chiefly from Acheen in Sumatra, and comes into the western markets in large masses packed in chests and casks, and presenting externally the impression of the reed mats in which they were originally contained.

Two kinds of benzoin are distinguishable in the market, one consisting chiefly of whitish tears united by a reddish brown connecting medium, the other of brown or blackish masses, without tears. The first is the most valuable, and has been called *benzoë amygdaloides*, from the resemblance of the white grains to fragments of blanched almonds: the second is sometimes called *benzoë in sortis*—benzoin in sorts—and usually contains numerous impurities. Between these two kinds there is every gradation. We have seen specimens of this balsam consisting exclusively of yellowish-white homogeneous fragments, which, when broken, presented a perfectly smooth, clear white, shining surface. These were no doubt identical in constitution with the tears of the larger masses.

Properties. Benzoin has an agreeable and fragrant odour, with very little taste; but when chewed for some time, leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish-brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. In the inferior kinds, the white spots are very few or entirely wanting. Benzoin is easily pulverized, and while in the process of being powdered is apt to excite sneezing. Its sp. gr. is from 1.063 to 1.092. When heated, it melts and emits thick, white, pungent fumes, which excite cough when inhaled, and consist chiefly of benzoic acid. It is wholly soluble, with the exception of impurities, in alcohol; and is precipitated by water from its solution, rendering the liquor milky like the gum-resins. It imparts to boiling water a notable proportion of benzoic acid. Lime-water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of another, having stronger affinity for the base. Its chief constituents are resin and benzoic acid; and it therefore belongs to the balsams. The white tears, and the brownish connecting medium, are said by Stolze to contain very nearly the same proportion of acid, which, according to Bucholz, is 12.5 per cent., to Stolze 19.8 per cent. The resin is of three different kinds, one extracted from the balsam along with the benzoic acid by a boiling solution of carbonate of potassa in excess, another dissolved by ether from the residue, and the third affected by neither of these solvents. Besides benzoic acid and resin, the balsam contains a minute proportion of extractive, and traces of volatile oil.

Medical Properties and Uses. Benzoin, like the other balsams, is stimulant and expectorant, and was formerly employed in various pectoral affections; but, except as an ingredient of the compound tincture of benzoin, it has fallen into almost entire disuse. It is employed in pharmacy for the preparation of benzoic acid (see *Acidum Benzoicum*); and the milky liquor resulting from the addition of water to its alcoholic solution, is sometimes used as a cosmetic, under the impression that it renders the skin soft and tender. In the East Indies it is burnt by the Hindoos as a perfume in their temples.

◆

BISMUTHUM. *U. S.*, *Lond.*, *Dub.*

Bismuth.

Tinglass; Etain de glace, Bismuth, *Fr.;* Wissmuth, *Germ.;* Bismuto, *Ital.;* Bismut. *Span.*

Bismuth is a peculiar metal, occurring usually in the metallic state, occasionally as a sulphuret, and rarely as an oxide. It is by no means generally diffused, being principally found in Saxony, Bohemia, and Transylvania. It occurs also in Cornwall, and has been found at Monroe, Conn., seventeen miles west of New-Haven, which is the only known locality in the United States. It is obtained almost entirely from the native bismuth. which is heated by means of wood or charcoal, whereby the metal is fused and becomes separated from its gangue. Almost all the bismuth of commerce comes from Saxony.

Bismuth was first distinguished as a peculiar metal by Agricola, in his treatise entitled Bermanus, published in 1520. Before that period, it was confounded with lead. It is a brittle, brilliant metal, of a peculiar yellowish-white colour and crystalline texture. Its crystals are in the form of cubes. It undergoes but a slight tarnish in the air. Its sp. gr. is 9.822, and its melting point 497°. At a high temperature, in close vessels, it volatilizes, and may be distilled over. When heated in the open air to a full red heat, it takes fire, and burns with a small blue flame, forming an oxide of a yellow colour. This is the *protoxide*, and consists of one equivalent of bismuth 71, and one equiv. of oxygen 8 = 79. Besides this oxide, bismuth forms a *sesquioxide* of a brown colour, very like the peroxide of lead, and consisting of two equiv. of metal 142, and three of oxygen 24 = 166. Bismuth is acted on feebly by muriatic acid, but violently by nitric acid, which dissolves it with a copious extrication of red fumes. Sulphuric acid when cold has no action on it, but at a boiling heat effects its solution with the extrication of sulphurous acid. As it occurs in commerce, it is generally contaminated with a little arsenic, the presence of which may be detected by its not being completely soluble in an excess of nitric acid. It may be purified from all contaminating metals, by dissolving the bismuth of commerce in nitric acid, precipitating the clear solution with water, and reducing the white powder thus obtained with black flux.

Pharm. Uses, &c. Bismuth, in an uncombined state, is not used in medicine, but is employed pharmaceutically to obtain the subnitrate of bismuth, the only medicinal preparation formed from this metal. In the arts, it is used to form a cosmetic, or white paint for the complexion, called *pearl white;* and it enters into the composition of the best pewter. Its consumption is limited by the small quantity of the metal which is supplied to commerce; this being computed not to exceed annually eleven or twelve thousand pounds.

BISTORTÆ RADIX. *Lond.*

Bistort Root.

"Polygonum Bistorta. *Radix.*" *Lond.*

Off. Syn. POLYGONI BISTORTÆ RADIX. *Ed.;* POLYGONUM BISTORTA. Radix. *Dub.*

Bistorte, *Fr.;* Natter-Wurzel, *Germ.;* Bistorta, *Ital., Span.*

POLYGONUM. *Sex. Syst.* Octandria Trigynia.—*Nat. Ord.* Polygoneæ.

Gen. Ch. Corolla five-parted, calycine. *Seed* one, angular. *Willd.*

Besides the bistort, some other plants belonging to this genus, have been used as medicines. Among these are the *P. aviculare* or knot-grass, a mild astringent formerly employed as a vulnerary and styptic; the *P. Persicaria* (Persicaria mitis), of a feebly astringent saline taste, and at one time considered antiseptic; and the *P. Hydropiper* or water-pepper (Persicaria urens), the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic. The water-pepper or smart-weed of this country—*P. punctatum* (Elliott), *P. Hydropiperoides* (Michaux), which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic ulcers, and internally in gravel. Dr. Eberle very strongly recommends it in amenorrhœa, in which complaint he has found no other remedy equally effectual. He gives a fluidrachm of the saturated tincture of the plant, or from four to six grains of the extract, three or four times a day. He has found it to produce a warmth and peculiar tingling sensation throughout the system, with slight aching pains in the hips and loins, and a sense of weight and tension within the pelvis. (*Eberle's Mat. Med. 4th ed.* vol. i. p. 441.) The *P. Fagopyrum* is the common buckwheat.

Polygonum Bistorta. Willd. *Sp. Plant.* ii. 441; Woodv. *Med. Bot.* p. 668. t. 232. This plant has a perennial root, and an annual herbaceous stem, which is simple, erect, jointed, and rises one or two feet in height. The lower leaves are cordato-lanceolate, and supported on long winged footstalks; the upper are ovate, almost sessile, amplexicaule, and sheathing. The flowers are of a pale rose colour, and form a close terminal spike. The plant is a native of Europe and the North of Asia.

The root, which is the officinal portion, is cylindrical, somewhat flattened, about as thick as the little finger, marked with annular or transverse wrinkles, furnished with numerous fibres, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. When dried, it is solid, brittle, of a deep brown colour externally, reddish within, destitute of smell, and possessed of a rough, astringent taste. It contains much tannin, some gallic acid and gum, and a large proportion of starch.

Medical Properties. Bistort resembles the other vegetable astringents, such as galls, kino, &c., in medical properties, and is applicable to the same complaints; but in this country is seldom or never used. It may be employed in the form of decoction or of powder. The dose of the latter is twenty or thirty grains, three or four times a day. W.

BOLETUS IGNIARIUS. *Ed.*

Agaric of the Oak. Touchwood. Spunk.

Amadouvier, Agaric de Chêne, *Fr.;* Feuerschwamm, *Germ.;* Esca, *Ital,;* Agarico, *Span.*

Boletus. *Sex. Syst.* Cryptogamia Fungi.—*Nat. Ord.* Fungi.

Gen. Ch. Fungus horizontal, porous beneath.

Several species belonging to this genus of mushrooms are used as food, several are poisonous, and two at least are officinal in Europe. The *Boletus laricis*, which grows upon the larch of the old world, is the *white agaric* or *purging agaric*, of medical writers. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but as found in commerce, is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. It has a sweetish very bitter taste, and consists, according to Braconnot, of 72 parts of resinous matter, 2 of bitter extractive, and 26 of fungin, a nutritious animalized principle, constituting the base of the fleshy substance of mushrooms. It contains also benzoic acid and various saline compounds. In the dose of four or six grains it is said to act powerfully as a cathartic; but Lieutaud asserts that it may be given in the quantity of thirty grains or a drachm without sensibly purging. M. Andral has found it useful in checking the night sweats of phthisis. He uses it in doses of eight grains, and gradually increases to a drachm during the day, without any observable inconvenience of the digestive functions. (*Journ. de Pharm.* xx. 599.) In this country it is scarcely employed, though we have met with it in the shops. That which is most esteemed is said to be brought from Siberia, but it is probably produced wherever the European larch tree grows. The species of Boletus which is directed by the Edinburgh College is the *B. igniarius*, which grows upon the decayed trunks of the oak, ash, and various other trees, and is common to the old and new continents.

Boletus igniarius. Sowerby, *Fung.* t. 34; Woodv. *Med. Bot.* p. 808. t. 273. The *Agaric of the oak*, like the species just described, is compared in shape to the horses hoof. Its diameter is from six to ten inches. When young it is soft like velvet, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colours more or less brown or blackish; on the under, it is whitish or yellowish and full of small pores; internally it is fibrous, tough, and of a tawny brown colour. It is composed of short tubular fibres compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting it is August or September. It has neither taste nor smell. Its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, animal matter also in small quantity, muriate of potassa, and sulphate of lime; and in its ashes are found iron and phosphate of lime and magnesia.

It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting hemorrhage. If steeped in a solution of nitre, and afterwards dried, it becomes very readily inflammable, and is applicable to the purposes of tinder. Some recommend the substitution of chlorate of potassa for nitre. The preparation is usually known by the name of *spunk*, and is brought to us from Europe.

Spunk or tinder, the *amadou* of the French, is in flat pieces, of a consistence somewhat like that of very soft rotten buckskin leather, of a brownish-yellow colour, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared from various other species of Boletus, as the *B. ungulatus*, *B. fomentarius*, *B. ribis*, &c.

Medical Properties, &c. The prepared agaric was at one time thought to have a peculiar property of arresting hemorrhage when compressed upon a bleeding vessel; but it is now believed to act mechanically, like any other soft porous substance, by absorbing the blood and causing it to coagulate, and is not relied on in severe cases. In the obstinate hemorrhage which occasionally takes place from leech bites, especially those of the European leech, it may be used advantageously, though perhaps not more so than well prepared lint.

It has been sometimes applied to the purposes of moxa. W.

◆

CALAMUS. *U.S. Secondary.*

Sweet Flag.

"Acorus calamus. Radix. *The root.*" *U.S.*

Off. Syn. CALAMI RADIX. Acorus Calamus. Radix. *Lond.;* ACORI CALAMI RADIX. *Ed.*

Acorus vrai, Acorus odorant, *Fr.;* Kalmuswurzel, *Germ.;* Calamo aromatico, *Ital., Span.*

Acorus. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Aroideæ.

Gen. Ch. Spadix cylindrical, covered with florets. *Corolla* six-petalled, naked. *Style* none. *Capsule* three-celled. *Willd.*

Acorus Calamus. Willd. *Sp. Plant.* ii. 199; Barton, *Med. Bot.* ii. 63. The sweet flag, or calamus, has a perennial, horizontal, jointed, somewhat compressed root, from half an inch to an inch thick, sometimes several feet in length, sending off numerous round and yellowish or whitish fibres from its base, and bunches of brown fibres resembling coarse hair from its joints, internally white and spongy, externally whitish with a tinge of green, variegated with triangular shades of light brown and rose colour. The leaves are all radical, sheathing at the base, long, sword-shaped, smooth, green above, but of a red colour variegated with green and white near their origin from the root. The scape or flower-stem resembles the leaves, but is longer, and from one side, near the middle of its length, sends out a cylindrical spadix, tapering at each end, about two inches in length, and crowded with greenish-yellow flowers. These are without calyx, and have six small, concave, membranous, truncated petals. The fruit is an oblong capsule, divided into three cells, and containing numerous oval seeds.

This is an indigenous plant, growing abundantly throughout the United States, in low, wet, swampy places, and along the sides of ditches and streams, and flowering in May and June. It is also a native of Europe and Western Asia; and a variety of the same species is found in India. The European plant differs from the American in some unimportant particulars. The leaves as well as root have an aromatic odour; but the latter only is used in medicine. After removal from the ground, the roots are washed, freed from their numerous fibres, and dried with a moderate heat. By the process of drying they lose nearly one half their diameter, but are improved in odour and taste.

Properties. The roots, as found in the shops, are in pieces of various lengths, somewhat flattened, externally wrinkled and of a yellowish-brown colour, and presenting on their under surface numerous minute circular spots, indicating the points at which the fibres were inserted. Their texture is light and spongy, their colour internally whitish or yellowish-white, and their fracture short and rough. Sometimes pieces are brought into the market consisting exclusively of the interior portion of the root. They are usually long, slender, irregularly quadrangular, and of a grayish-white colour; and are prepared by paring off the outer coat with a knife. The odour of calamus is strong and fragrant; its taste, warm, bitterish, pungent, and aromatic. Its active principles are taken up by boiling water. From one hundred parts of the fresh root of the European plant, Trommsdorff obtained 0.1 part of volatile oil, 2.3 of a soft resin, 3.3 of extractive with a little muriate of potassa, 5.5 of gum with some phosphate of potassa, 1.6 of starch analogous to inulin, 21.5 of lignin, and 65.7 of water. Sixteen ounces of the dried root afforded to Neumann about two scruples of volatile oil. The oil is at first yellow, but ultimately becomes red, and has the smell and taste of calamus. The extractive matter has an acrid and sweetish taste. The root is sometimes attacked by worms, and deteriorates by keeping.

The root of the Indian variety is said to be less thick than the European, and to have a stronger and more pleasant taste and smell. It is supposed by some to be the true calamus of the ancients, though the claims of either variety to this honour have not been certainly established.

Medical Properties and Uses. Calamus is a stimulant tonic, possessing the ordinary virtues of the aromatics. It may be taken with advantage in pain or uneasiness of the stomach or bowels arising from flatulence; and forms a useful adjuvant to tonic or purgative medicines in cases of torpor or debility of the alimentary canal. The calamus of the ancients was in high repute; and its virtues are celebrated in the works of Pliny and Dioscorides. By modern physicians the medicine is much neglected, though well calculated to answer as a substitute for more costly aromatics. The dose in substance is from a scruple to a drachm. An infusion, made in the proportion of an ounce of the root to a pint of boiling water, is sometimes given in the dose of a wineglassful or more. W.

CALX. *U. S., Lond., Dub.*

Lime.

Quicklime; Chaux, *Fr.;* Kalk, *Germ.;* Calce, *Ital.;* Calviva, *Span.*

Lime is placed in the materia medica list of the United States, Edinburgh, and Dublin Pharmacopœias, but among the Preparations in the London. It is a very important pharmaceutical agent, and forms the basis or principal ingredient in several standard preparations.

Lime is a very abundant natural production. It is never found pure, but mostly combined with acids; as for example, with carbonic acid in chalk, marble, calcareous spar, limestone, and shells; with sulphuric acid in the different species of gypsum or plaster of Paris; with phosphoric acid in the bones of animals, and with silica in a great variety of minerals.

Preparation. Lime is prepared by calcining, with a strong heat, some form of the native carbonate. The carbonic acid is thus expelled, and the lime remains behind. When the lime is intended for nice chemical operations, it ought to be obtained from pure white marble or oyster shells. For the purposes of the arts, it is generally procured from common limestone, by calcining it in kilns of peculiar construction. When obtained in this way, it is generally impure, being of a grayish colour, and containing alumina, silica, and oxide of iron, and occasionally a little magnesia and oxide of manganese.

The officinal lime of the United States, Edinburgh, and Dublin Pharmacopœias is the lime of commerce, and is, therefore, impure. That of the London College is comparatively pure. It is directed by this College, to be prepared by taking a pound of white marble, and exposing it, broken into pieces, in a crucible, to a violent heat for an hour, or until the carbonic acid has been entirely expelled; so that on the addition of dilute acetic acid, no effervescence is produced. This College also prepares another variety of lime from oyster shells, by the method just given. (See *Calx è Testis.*)

It may well be questioned whether it is necessary to have a purer officinal lime than the commercial varieties of this earth; and hence whether the London College is judicious in giving a formula for its preparation from white marble. In pharmaceutical processes, where the lime acts as a mere chemical agent, its entire purity is not essential; and in preparing lime-water, the usual impurities in the commercial lime, being insoluble, would not prove hurtful.

Properties. Lime is a white solid, having a strong, caustic, alkaline taste, and the sp. gr. 2.3. It is very refractory in the fire, having been fused only by the compound blow-pipe of Dr. Hare. Exposed to the air, it absorbs moisture and carbonic acid, and falls to powder. In this state, it is a mixture of carbonate and hydrate. On account of this liability to change by being kept, the Edinburgh and Dublin Colleges direct their officinal lime to be recently burnt. It acts upon vegetable colours as a strong alkaline base, changing syrup of violets green, and tincture of tumeric, red. It has a strong affinity for water, and is capable of combining with it both as a hydrate and a solution. When sprinkled with this liquid, it heats, produces a hissing noise, and is reduced to the state of a white pulverulent hydrate. In this state, it is called slaked lime. It is but sparingly soluble in water, requiring about seven hundred times its weight of that liquid for complete solution at the temperature of 60°. In hot water, contrary to the general law, it is less soluble than in cold. The solution formed is called lime-water.

Lime is the oxide of a peculiar metal, called calcium, and consists of one equivalent of calcium 20.5, and one equiv. of oxygen 8 = 28.5. It is distinguished from the other earths by forming a very deliquescent salt with muriatic acid, and a very voluminous and sparingly soluble one with sulphuric acid. All acids and acidulous salts, alkaline carbonates, ammoniacal and metallic salts, borates, and astringent vegetable infusions, are incompatible with it. It forms a numerous class of salts with acids, several of which are officinal.

Medical Properties. Lime acts externally as an escharotic, and was formerly applied to ill-conditioned ulcers. It is a powerful antacid; but when used with this intention, it is always administered in solution. (See *Liquor Calcis.*) Its principal uses connected with medicine are as a pharmaceutical agent.

Economical Uses. The uses of lime in the arts are numerous. It is employed in the fabrication of soap, to render the fixed alkalies caustic; as a manure for fertilizing fields; and mixed with sand and water, as the ordinary cement of buildings. When it improves the fertility of lands, it does not act as an aliment to the plants, but merely as an agent in accelerating the decomposition of the organic remains existing in the soil.

* * *

CALCII CHLORIDUM. *U.S.*

Chloride of Calcium.

Off. Syn. CALCIS MURIAS. *Lond.*, *Dub.*

Muriate of lime; Chlorure de calcium, Hydrochlorate de chaux, *Fr.;* Chlorcalcium, Salzsaurer Kalk, *Germ.*

Chloride of calcium is a compound of chlorine and the metallic radical of lime, called calcium. It is placed in the list of the materia medica in the United States Pharmacopœia, but among the Preparations in the London and Dublin, under the name of muriate of lime. It may be readily formed by saturating muriatic acid with marble or chalk, evaporating to dryness, and heating to redness. The muriatic acid, by reacting with the lime, forms chloride of calcium and water, the latter of which is dissipated at a red heat.

The London College forms this chloride by taking two pounds of the salt which remains after the sublimation of carbonate of ammonia, and acting on it with water. The solution obtained is filtered and evaporated to dryness, and the dry mass kept in well-stopped bottles. The residuum here employed is chloride of calcium, mixed with some carbonate of lime; and the process of the College has for its object merely to purify the chloride from the carbonate, the water dissolving the former, and leaving the latter.

In making chloride of calcium, the Dublin College uses the residuum of their process for obtaining water of ammonia. The latter preparation being procured by the action of lime on muriate of ammonia, the residuum is evidently a solution of chloride of calcium, or muriate of lime; but it generally contains adhering ammonia and an excess of lime. Any quantity of this residuum is taken, and, after being filtered, is evaporated to dryness. The excess of lime may be saturated with muriatic acid, or converted into an insoluble carbonate by exposing the solution for some time to the air.

Properties. Chloride of calcium is an acrid, bitter, and very deliquescent salt, soluble in about one-fourth of its weight of water at 60°. It crystallizes, but with difficulty, in six-sided prisms. Its crystals, on exposure to heat, first dissolve in their water of crystallization, and after this has evaporated, undergo the igneous fusion. This salt produces cold by its solution, and is an efficient ingredient in freezing mixtures. On account of its avidity for water, it is used for drying gases, and for bringing alcohol to its highest degree of concentration. It is employed for the latter purpose by the Dublin College. When sulphuric acid is added to a concentrated solution of it, muriatic acid gas is copiously evolved, and the whole becomes a thick mass of sulphate of lime. A similar change in consistence is produced by the addition of a concentrated solution of potassa, in consequence of the precipitation of lime.

Chloride of calcium exists in the solid state in the materials from which nitre is extracted, and in solution in the water of the ocean and of many springs. It is usually associated with common salt and muriate of magnesia, from which salts it is separated with difficulty.

Composition. Chloride of calcium consists of one equivalent of chlorine 35.42, and one equiv. of calcium 20.5=55.92. When crystallized, it contains six equiv. of water=54. On the old theory, which made it a dry muriate, it was supposed to consist of one equiv. of hypothetical dry muriatic acid 27.42, and one equiv. of lime 28.5, giving the same equiv. for the compound as by the other view. On the new theory also, it may, when in solution, be assumed to be a muriate, generated by the hydrogen of water combining with the chlorine, and its oxygen with the calcium.

Medical Properties. Chloride of calcium is deobstruent and tonic. It is occasionally administered in pill, combined with conium; but is chiefly used medicinally in the form of solution, when it may be considered to become a muriate of lime. In this form it is officinal in the United States and British Pharmacopœias. For its medical properties more in detail, see *Liquor Calcis Muriatis.*

Off. Prep. Liquor Calcis Muriatis, *Lond.*, *Dub.* B

* * *

CALCIS CARBONAS, *U.S.*

Carbonate of Lime.

Off. Syn. CRETA. *Lond.;* CARBONAS CALCIS MOLLIOR. CRETA ALBA. *Ed.;* CALCIS CARBONAS. CRETA ALBA. *Dub.*

Chalk; Carbonate de chaux, Craie, *Fr.;* Kohlensaurer Kalk, Kreide, *Germ.;* Calce carbonate, Creta, *Ital.;* Greda, *Span.*, *Port.*

Carbonate of lime, in the chemical sense, is the salt formed by the combination of carbonic acid with lime, whether occurring native or formed artificially, and under whatever form it may be observed. In the pharmaceutical sense, however, of the United States Pharmacopœia, it means that peculiar variety of native carbonate of lime, which is soft and friable, and known under the common name of *chalk.*

Carbonate of lime, in the extended meaning of the term, is the most abundant of simple minerals, constituting, according to its state of aggregation and other peculiarities, the different varieties of calcareous spar, common and shell limestone, marble, marl, and chalk. It occurs also in the animal kingdom, forming the principal part of the shells of many animals. Though insoluble in pure water, yet it is present in minute quantity in most natural waters, being dissolved in the carbonic acid which they contain. In the waters of limestone districts, it is a very usual impregnation, and causes purging in those not accustomed to their use. In all such cases, boiling the water, by expelling the carbonic acid, causes the carbonate to be deposited. Besides being officinal in its soft state as chalk, carbonate of lime is also ordered as it exists in marble, oyster-shells, crabs' claws, and crabs' stones. (See *Calcis Carbonas Durus*, U.S.; *Testa*, U.S.; *Carbonas Calcis ex Cancro Paguro*, Ed.; *Carbonas Calcis ex Cancro Astacho*, Ed.) In the present article we shall restrict our observations to chalk.

Localities. Chalk occurs abundantly in the South of England and North of France, and is found also in Ireland, Poland, and several islands of the Baltic. It has not been discovered in the United States, and the consumption of this country is supplied from England. It occurs massive in beds, and very frequently contains nodules of flint, and fossil remains of land and marine animals.

Properties. Chalk is an insipid, inodorous, insoluble, opaque solid, generally white, but sometimes yellowish, or grayish-white. It is rough to the touch, moderately hard and easily pulverized, and breaks with an earthy fracture. It soils the fingers, yields a trace when drawn across an unyielding surface, and when applied to the tongue adheres slightly. Its sp. gr. varies from 2.3 to 2.6. It is not a perfectly pure carbonate of lime, but contains, besides gritty siliceous particles, minute portions of alumina and of oxide of iron. Like all carbonates, it effervesces with acids, and with the muriatic forms a very deliquescent salt. Though insoluble in water, it dissolves in an excess of carbonic acid. It consists, like the other varieties of carbonate of lime, of one equivalent of carbonic acid 22.12, and one equiv. of lime $28.5=50.62$.

Pharmaceutical Uses. Chalk, on account of its hardness and the gritty particles which it contains, is unfit for medical use, until it has undergone levigation, when it forms the prepared carbonate of lime. (See *Calcis Carbonas Præparatus.*)

◆

CALCIS CARBONAS DURUS. *U.S.*

Hard Carbonate of Lime.

Off. Syn. MARMOR ALBUM, *Lond.;* CARBONAS CALCIS DURIOR. MARMOR ALBUM, *Ed.;* CALCIS CARBONAS. MARMOR ALBUM. *Dub.*

White marble; Marbre, *Fr.;* Marmor, *Germ.;* Marmo, *Ital.;* Marmol, *Span.*

By "hard carbonate of lime," in the United States Pharmacopœia, is intended to be designated that variety of granular limestone, familiarly called white marble. Its principal officinal use is to yield carbonic acid by the action of the strong acids, in order to impregnate water and various solutions with it. For this purpose, no nicety is required in the selection of the limestone employed; but for other purposes, such as for preparing the solution of muriate of lime, a pure carbonate is necessary, and hence white marble is selected.

The whitest and purest marbles are the Carara, Luni, and Parian; but it is not expected, nor is it desirable that these should be exclusively selected for pharmaceutical use. Good marble abounds in most parts of the world, and in the United States, pure kinds are to be met with in numerous localities. White marble may be known by its colour and granular texture, and by its effervescing with acids. Its sp. gr. varies from 2.7 to 2.84. In composition it agrees with the carbonate of lime.

* * *

CARBONAS CALCIS EX CANCRO ASTACHO, *vulgo* LAPILLI CANCRORUM. *Ed.*

Carbonate of Lime from the Crawfish, commonly called *Crab Stones.*

Crabs' eyes; Yeux d'écrevisse, *Fr.;* Krebsaugen, Krebssteine, *Germ;* Ojos de cangrejo, *Span.*

The officinal crab stones are a peculiar concretion, found in the stomach, one on each side, of the European crawfish, at the time the animal is about to change its shell. After the new shell is completed, they disappear; and hence, with every appearance of probability, they may be considered as intended to assist in its formation.

The crawfish of Europe is now referred to the genus *Astacus*, and is called *Astacus fluviatilis* by Fabricius. It is a small animal, having a general resemblance to the lobster. The snout is projecting, and serrated on the sides; and the thorax and back are smooth, the latter being furnished laterally with two small spines. The large claws are studded with small tubercles. The two first pairs of legs are clawed, the two next subulated, and the tail is five-jointed with rounded fins. It inhabits lakes and rivers.

The crawfish of Europe has not been found in the United States; but two American species of Astacus, closely allied to the *A. fluviatilis*, and confounded under the name of crawfish, or fresh-water lobster, have been described, one by Bosc under the name of *A. Bartonii*, the other by Say under the appellation of *A. affinis*. The former is very common, inhabiting rivulets and small streams of fresh water. The latter is larger than the *Bartonii*, and bears a very close resemblance to the European species, to which Mr. Say states he would have referred it, had it not been for the circumstance that in his species, the claws are not tuberculated. We are not informed whether the American species are furnished with the stomachic concretions; but there is every reason to believe that they follow the analogy of the European crawfish in this respect.

Crab stones are most abundantly procured in the province of Astracan in Asiatic Russia. The crawfish are bruised with wooden mallets and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out.

Properties. Crab stones are inodorous, insipid bodies, somewhat hemispherical in shape, of a white or reddish colour, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, but in consequence of the animal matter which they contain, do not entirely dissolve, but become converted into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated from chalk, mixed with mucilaginous substances. In composition they resemble crabs' claws, their constituents being carbonate and phosphate of lime, cemented together by animal matter.

Medical Properties. Crab stones are occasionally used as an absorbent and to correct acidity in the primæ viæ; but it may well be doubted whether, for these purposes, they are equal in efficacy to the common prepared chalk. Before being exhibited they require to be prepared by levigation, a circumstance omitted to be stated in the Edinburgh Pharmacopœia. The dose varies from one to two drachms, suspended in any proper vehicle. (See *Calcis Carbonas Præparatus*, U.S.) B.

* * *

CARBONAS CALCIS EX CANCRO PAGURO, *vulgo* CHELÆ CANCRORUM. *Ed.*

Carbonate of Lime from the Black-clawed Crab, commonly called *Crabs' Claws.*

Serres d'écrevisse, *Fr.;* Krebsscheeren, *Germ.;* Chele di granchi, *Ital.;* Pierna de cangrejo, *Span.*

This form of carbonate of lime is not to be found in the London, Dublin, or United States Pharmacopœias; and it is very properly omitted, as no effect could be expected from it, which might not be better obtained from the use either of prepared chalk, or prepared oyster-shells.

We are indebted to Mr. Hatchett and Mérat-Guillot for our knowledge of the composition of the coverings of the crustaceous animals. They are found to be composed of a large quantity of carbonate of lime, a small quantity of the phosphate of lime, and a portion of animal matter of the nature of coagulated albumen. We are not acquainted with any analysis of the officinal crabs' claws; but the crust of the lobster, which must be nearly identical, was found by Mérat-Guillot to consist, in the 100 parts, of carbonate of lime 60, phosphate of lime 14, and animal matter 26.

It is not at all probable that the phosphate of lime and animal matter in crabs' claws, confer upon them any peculiar powers as a medicinal agent; and hence their introduction into the materia medica may be considered as a useless refinement. When used, they must be prepared by trituration and levigation; and yet the Edinburgh College has omitted to give any directions to that effect.

The animal designated by the Edinburgh College as furnishing this form of carbonate of lime, is the *Cancer pagurus*, a species of European crab, not found in our waters. It is probable, however, that the edible crab of our country (*Lupa hastata*) would furnish an identical preparation.

Medical Properties. Crabs' claws act as an absorbent and antacid, but are less efficacious in these respects than prepared carbonate of lime. (See *Calcis Carbonas Præparatus.* U.S.)

B.

CAMPHORA. *U.S.*

Camphor.

"Dryobalanops camphora. *Colebrooke.* Laurus camphora. *Willd.* Concretum sui generis. *A peculiar concrete substance.*" *U.S.*

Off.Syn. CAMPHORA. Laurus Camphora, Concretum sui generis sublimatione paratum. *Lond.;* CAMPHORA. Ex Lauro Camphora. *Ed.;* CAMPHORA. LAURUS CAMPHORA. DRYOBALANOPS CAMPHORA. Camphora. *Dub.*

Camphre, *Fr.;* Kampher, *Germ.;* Canfora, *Ital.;* Alcanfor, *Span.*

Camphor is not confined to any one species or even genus of plants. Though not an abundant principle, it is widely diffused; existing not only in the plants recognised by the U.S. Pharmacopœia, but also in the roots of the cinnamon, cassia, and sassafras laurels; in those of the galanga, zedoary, and ginger; in the seeds of the cardamom and long-pepper; and in the essential oils of lavender, sage, thyme, peppermint, and rosemary. It varies somewhat in properties, as furnished by these various plants; and in most of them exists in quantities too small to admit of profitable extraction. The inhabitants of Ceylon are said to procure it from the root of the *Laurus Cinnamomum;* and Zea describes a variety which exudes from the bark of an unknown tree in South America, and is collected by the natives; but the camphor of commerce is derived exclusively from the *Laurus Camphora* and the *Dryobalanops Camphora.*

1. *Laurus Camphora.*

Laurus. *Sex.Syst.* Enneandria Monogynia.—*Nat. Ord.* Laurineæ.

Gen.Ch. *Calyx* none. *Corolla* calycine, six-parted. *Nectary* with three two-bristled glands, surrounding the germ. *Filaments* interior, glanduliferous. *Drupe* one-seeded. *Willd.*

Among the species composing the genus Laurus of Linn., such striking differences have been observed in the structure of the flower and fruit, that some botanists have been induced to arrange them in new genera, which do not, however, yet appear to have been sufficiently established to authorize their adoption in this work. The camphor, cinnamon, and sassafras laurels are referred by Sprengel to the genus Persea of Gærtner, while even this has been divided by other botanists.

Laurus Camphora. Willd. *Sp. Plant.* ii. 478; Woodv. *Med. Bot.* p. 681. t. 236.—*Persea Camphora.* Sprengel. The camphor laurel is an evergreen tree of considerable size, having the aspect of the linden, with a trunk straight below, but divided above into many branches, which are covered with a smooth greenish bark. Its leaves, which stand alternately upon long footstalks, are ovate lanceolate, entire, smooth and shining, ribbed, of a pale yellowish-green colour on their upper surface, glaucous on the under, and two or three inches in length. The flowers are small, white, pedicelled, and collected in clusters, which are supported by long axillary peduncles. The fruit is a red berry resembling that of the cinnamon. It is a native of the most eastern parts of Asia, and is found abundantly in China and Japan. It has been introduced into the botanical gardens of Europe, and is occasionally met with in the hot-houses of our own country; but we are informed by Woodville, that in England, though it often appears sufficiently luxuriant and healthy, it very rarely produces flowers.

The camphor is diffused through all parts of the plant, and is obtained from the root, trunk, and branches, by sublimation. The process is not precisely the same in all places; but the following is perhaps the most prevalent. The parts mentioned, particularly the roots and smaller branches, are cut into chips, which are placed, with a little water, in large iron vessels, surmounted by earthen capitals, furnished with a lining of rice-straw. A moderate heat is then applied, and the camphor, volatilized by the steam of the boiling water, rises into the capital, where it is condensed upon the straw.

2. *Dryobalanops Camphora.*

It was long since known that an excellent variety of camphor was produced in the islands of Sumatra and Borneo, by a forest tree which was thought by some to belong to the genus Laurus, by others was considered wholly distinct, but which, not having been seen by scientific botanists, remained for a long period undescribed. Kœmpfer stated that it was not akin to the laurel; and Dr. Roxburgh, from a rough sketch of the fruit and leaf which he received while in India, was induced to refer it to the genus Shorea; under the title of *S. camphorifera;* but though belonging to the same natural family with the Shorea, it differs in its generic character. This, Mr. Colebrooke, president of the Asiatic Society, was at length enabled to decide, from specimens of the seeds and some living plants which came into his possession. His description, however, is somewhat defective, as the plants soon died, and he had no opportunity of inspecting the flower in its perfect state. The genus he ascertained to be the Dryobalanops of the younger Gærtner, founded upon a specimen which had been received from India, but with very incorrect information as to the locality and uses of the plant from which it was derived.

Dryobalanops. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Diterocarpeæ.

Gen. Ch. Calyx one-leaved, permanent, enlarged into a gibbous cup, with five ligulate, long scariose wings. *Corolla* five-petalled. *Capsule* three-valved, one-celled. *Seed* solitary. *Embryo* inverse, without perisperm.

Dryobalanops Camphora. Colebrooke, *Asiat. Research.* xii. 539. This is the only known species of its genus. It is a very large forest tree, attaining sometimes to the height of one hundred feet, with a trunk six or seven feet in diameter. The bark is of a brownish colour. The leaves are alternate above, opposite below, elliptical, obtusely acuminate, with parallel veins, entire, smooth, nearly four inches long, and rather more than an inch broad. The flowers, according to Houttuyn, are large and like those of the tulip. This tree is a native of Sumatra and Borneo, growing abundantly on the N. W. coast of the former island, and ranking among the tallest and largest trees of that luxuriant country.

The camphor of the Dryobalanops exists in concrete masses, which occupy longitudinal cavities or fissures in the heart of the tree, from a foot to a foot and a half long, at certain distances apart. The younger trees are generally less productive than the old; and the number of those which furnish a quantity of the drug sufficient for extraction is comparatively small. The natives have no certain means of discovering the trees which contain the camphor, except by making incisions into them. A party proceeds through the forest, wounding the trees till they find one which will answer their purpose, and hundreds may be examined before this object is attained. When discovered, the tree is felled and cut into logs, which are then split, and the camphor removed. The greater part is taken out by sharp-pointed instruments; and the sides of the cavity are then scraped, so as to separate any adhering portion. The latter is less highly valued, in consequence of the small chips or fragments of wood which are mingled with it. The masses are sometimes as thick as a man's arm; and the product of a middling sized tree is nearly eleven pounds; of a large one, double the quantity. The trees which have been cut and left standing, often produce camphor seven or eight years afterwards. The Dryobalanops also yields a fragrant liquid, called in the East Indies *oil of camphor*, and highly valued as an external application in rheumatic and other painful affections. It is said to be found in trees which have not attained a sufficient age to produce camphor, and is supposed to constitute the first stage in the development of this substance, as it occupies the same cavities in the trunk, which are afterwards filled with the camphor. It holds in fact a large proportion of this principle in solution, and may be made to yield an inferior variety by artificial concretion. It is highly probable that the camphor is deposited from it by a natural crystallization in the crevices of the wood where it is found. The whole tree is probably pervaded by this camphorous juice, as the wood retains a fragrant smell, and being on this account less liable to the attacks of insects, is highly esteemed for carpenters' work.

Commercial History. Camphor is brought to this country from Calcutta, Batavia, and Canton; and frequently also from London, where it is purchased at the East India Company's sales. Most, if not all of it, is derived, originally from the dominions of China and Japan; though Ainslee states, that the greater part of the camphor found in the India bazaars, is obtained from Sumatra and Borneo. It is possible that the inferior qualities of that obtained from the Dryobalanops Camphora in these islands, may be taken to Calcutta, and thence enter the general market; but the quantity must be small, as the product of this tree is nearly all engrossed by the Chinese, by whom it is said to be so highly valued, that it commands at Canton from twelve to twenty times the price of ordinary camphor. Dr. Duncan, in the last edition of his Dispensatory, describes a specimen of the camphor of the Dryobalanops in his possession, as being in tabular plates, somewhat translucent, easily pulverizable without the addition of alcohol, more compact and heavy than common camphor, not agglutinating like this when in powder, nor rising spontaneously in vapour so as to crystallize on the sides of the bottles in which it is contained. We have not seen any parcel that answers to this description in our market; and the probability is, that little or none is imported.

Crude camphor, as brought from the East, is usually in small grains or granular masses, which are of a dirty white colour, and are frequently mingled with extraneous matters. In this state it is never found in the shop of the apothecary. It must be refined before it can be used for medicinal purposes. The process for refining camphor was first practised in Europe by the Venetians, who probably derived it from the Chinese. It was afterwards transferred to the Dutch, who long enjoyed a monopoly of this business; and it is only within a few years, that the process has been generally known. It is now practised largely in this country, and the camphor refined in our domestic establishments is equal to any that was formerly imported. The crude camphor is mixed with a small proportion of quicklime,* and exposed in a glass or earthenware vessel placed in a sand bath, to a gradually increasing heat, by which it is melted, and ultimately converted into vapour, which condenses in a suitable recipient. Refined in this manner, it is usually in the form of large circular cakes, one or two inches thick, convex on one side, concave on the other, and perforated in the centre.

---

* Six drachms of lime to two pounds and a half of camphor, French weight, or about 1 part to 50, is the proportion employed in the process of M. Clémandot, which enjoys some reputation in France. *Journ. de Pharm.* ii. 321.

Properties. Camphor has a peculiar, strong, penetrating, fragrant odour; and a bitter, pungent taste, attended with a slight sense of coolness. It is beautifully white and pellucid, somewhat unctuous to the touch, friable, and yet possessed of a degree of tenacity which renders its reduction to a fine powder very difficult, unless the cohesion of its particles be overcome by the addition of a minute proportion of alcohol or other volatile liquid for which it has an affinity. It has a shining fracture, and a crystalline texture. Its sp. gr. varies from 0.9857 to 0.996. It therefore floats upon water, on the surface of which, if thrown in small fragments, it assumes very singular circulatory movements, which cease upon the addition of a drop of oil. Its volatility is so great, that even at ordinary temperatures it is wholly dissipated if left exposed to the air. It melts at 288° F. and boils at 400°. (*Turner.*) In close vessels it may be sublimed unchanged. When allowed to concrete slowly from the state of vapour, it assumes the form of hexagonal plates. Dr. Paris tells us, on the authority of Mr. W. Phillips, that the native crystal of camphor is a flat octohedron. It is not altered by air and light. It readily takes fire, and burns with a brilliant flame, giving out much smoke, and leaving no residue. Water triturated with camphor dissolves a very minute proportion, not more, according to Berzelius, than the thousandth part of its weight; which, however, is sufficient to impart a decided odour and taste to the solvent. By the intervention of sugar or magnesia, particularly of the latter, a much larger proportion of the camphor is dissolved. (See *Aqua Camphoræ.*) Carbonic acid also increases the solvent power of water. Alcohol will take up seventy-five per cent. of its weight of camphor, which is precipitated upon the addition of water. Berzelius states, that 100 parts of alcohol of the sp. gr. 0.806, dissolve 120 parts at 50° F. It is soluble also without change in ether, the volatile and fixed oils, strong acetic acid, and the diluted mineral acids. By the action of strong sulphuric and nitric acids it is decomposed, the former carbonizing and converting it into artificial tannin; the latter, by the aid of repeated distillation, into a peculiar acid called the *camphoric*. The alkalies produce very little effect upon it. The resins unite with it, forming a soft tenacious mass; and a similar softening effect results when it is triturated with the concrete oils. Exposed to a strong heat in close vessels, camphor is decomposed, being resolved into a volatile oil and charcoal. It is closely analogous in character to the essential oils. Berzelius considers it a stearoptene entirely free from any mixture of eleoptene. (See *Olea Volatilia.*) According to M. Dumas, it consists of a peculiar base called *camphene* united with oxygen. Camphene, is a volatile liquid, composed of 8 equiv. of hydrogen 8, and 10 equiv. of carbon 61.2=69.2. With 1 equiv. of oxyen it forms camphor, with 2 equiv. of the same body camphoric acid, and with 1 equiv. of hydrochloric acid, artificial camphor.

Medical Properties and Uses. Camphor does not seem to have been known to the ancient Greeks and Romans. Europe probably derived it from the Arabians, by whom it was employed as a refrigerant. Much difference of opinion has prevailed as to its mode of action, some maintaining its immediate sedative influence, others considering it as a direct and decided stimulant. Its operation appears to be primarily and chiefly directed to the cerebral and nervous systems; and the circulation, though usually affected to a greater or less extent, is probably involved only through the agency of the brain. The effects of the medicine vary with the quantity administered. In moderate doses it produces, in a healthy individual, mental exhilaration, increased heat of skin, and occasional diaphoresis. The pulse is usually increased in fulness, but little, if at all, in force or frequency. According to the recent experiments of certain Italian physicians, it appears to have a tendency to the urinary and genital organs, producing a burning sensation along the urethra, and exciting voluptuous dreams.* Cullen, however, states that he has employed it fifty times, even in large doses, without having ever observed any effect upon the urinary passages. In its primary operation it also allays nervous irritation, quiets restlessness, and produces a general placidity of feeling, which renders it highly useful in certain forms of disease attended with derangement of the nervous functions. In larger doses it displays a more decided action on the brain, producing more or less giddiness and mental confusion, with a disposition to sleep; and in morbid states of the system, relieving pain, and allaying spasmodic action. In immoderate doses it occasions nausea, vomiting, anxiety, faintness, vertigo, delirium, insensibility, coma, convulsions, and sometimes death. The pulse, under these circumstances, is at first reduced in frequency and force;† but as the action advances, it sometimes happens that symptoms of strong sanguineous determination to the head become evident, in the flushed countenance, inflamed and fiery eyes, and highly excited pulse.‡

By its moderately stimulating powers, its diaphoretic tendency, and its influence over the nervous system, it is admirably adapted to the treatment of all diseases of a typhoid character, which combine with the enfeebled condition of the system, a frequent irritated pulse, a dry skin, and much nervous derangement, indicated by restlessness, watchfulness, tremors, subsultus, and low muttering delirium. Nor are its beneficial effects confined to typhoid diseases. With a view to its anodyne and narcotic influence, it is often used in those of an inflammatory character, as in our ordinary remittents, and the phlegmasiæ, particularly rheumatism, when the increased vascular action is complicated with derangement of the nervous system. In such cases, however, it should never be used until after proper depletion, and even then should be combined with such medicines as may obviate the slight stimulation it produces, and give it a more decided tendency to the skin; as, for instance, tartarized antimony, ipecacuanha, or nitre. In a great number of spasmodic and nervous disorders, and complaints of irritation, camphor has been very extensively employed. The cases of this nature to which experience has proved it to be best adapted, are dysmenorrhœa, puerperal convulsions and other nervous affections of the puerperal state, and certain forms of mania, particularly nymphomania, and that arising from the abuse of spirituous liquors. In some of these cases advantage may be derived from combining it with opium. Camphor has also been employed internally to allay that irritation of the urinary organs which is apt to be produced by cantharides.

It is much used externally as a local anodyne, generally dissolved in alcohol, oil, or acetic acid, and frequently combined with laudanum. In rheumatic and gouty affections, and various internal spasmodic and inflammatory complaints, it often yields relief when applied in this way. The ardor urinæ of gonorrhœa may be alleviated by injecting an oleaginous solution of camphor into the urethra; and the tenesmus from ascarides and dysentery, by administering the same solution in the form of enema. A scruple or half a drachm of camphor in substance, added to a poultice, and applied to the perineum, allays the chordee, which is a painful attendant upon gonorrhœa.

---

* N. Am. Med. and Surg. Journ. vol. ix. p. 442.

† Alexander. Experimental Essays, p. 227.—Orfila.

‡ Quarin, quoted by Woodville, Med. Bot., 2d ed., vol. iv. p. 687.

The vapour of camphor has been inhaled into the lungs with benefit in cases of spasmodic cough; and a lump of it held to the nose is said to relieve that unpleasant fulness of the nostrils and coryza which attend a commencing catarrh.

Camphor may be given in substance in the form of bolus or pill, or diffused in water by trituration with various substances. The form of pill is objectionable, as in this state the camphor is with difficulty dissolved in the gastric liquors, and floating on the top, is apt to excite nausea, or pain and uneasiness at the upper orifice of the stomach. Orfila states, that when given in the solid form it is capable of producing ulceration in the gastric mucous membrane. The emulsion is almost always preferred. This is made by rubbing up the camphor with loaf sugar, gum Arabic, and water; and the suspension will be rendered more complete and permanent by the addition of a little myrrh. Milk is sometimes used as a vehicle, but is objectionable, as it is apt to become sour very speedily. The aqueous solution is often employed where only a slight impression is desired. For this purpose, the *Aqua Camphoræ* of the United States Pharmacopœia is preferable to the solution effected by simply pouring boiling water upon a lump of camphor, which is sometimes prescribed under the name of *camphor tea.*

The medium dose of camphor is from five to ten grains; but to meet various indications it may be diminished to a single grain or extended to a scruple. The injurious effects of an overdose are said to be best counteracted, after clearing out the stomach, by the use of opium.

CANELLA. *U.S.*

Canella.

"Canella alba. Cortex. *The bark.*" *U.S.*

Off. Syn. CANELLÆ CORTEX. Canella alba. Cortex. *Lond.;* CANELLÆ ALBÆ CORTEX. *Ed.;* CANELLA ALBA. Cortex. *Dub.*

Cannelle blanche, *Fr.;* Weisser Zimmt, Canell, *Germ.;* Cannella bianca, *Ital.;* Canela blanca, *Span.*

CANELLA. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Meliaceæ.

Gen. Ch. Calyx three-lobed. *Petals* five. *Anthers* sixteen, adhering to an urceolate nectary. *Berry* one-celled with two or four seeds. *Willd.*

Canella was first made a distinct genus by the celebrated Professor Murray. It had previously been confounded, under the name of *Winterania*, with that to which the tree that produces the Winter's bark belongs. The latter is now recognised as a distinct genus with the title of *Drymis* or *Wintera.*

Canella alba. Willd. *Sp. Plant.* ii. 851; Woodv. *Med. Bot.* p. 694. t. 237. This is an erect tree, rising sometimes to the height of fifty feet, branching only at the top, and covered with a whitish bark, by which it is easily distinguished from other trees in the woods where it grows. The leaves are alternate, petiolate, oblong, obtuse, entire, of a dark green colour, thick and shining like those of the laurel, and of a similar odour. The flowers are small, of a violet colour, and grow in clusters upon divided footstalks, at the extremities of the branches. The fruit is an oblong berry, containing one, two, or three black and shining seeds.

The Canella alba grows naturally in Jamaica and other West India islands. The bark of the branches, which is the part employed in medicine, having been removed by an iron instrument, is deprived of its epidermis, and dried in the shade. It comes to us in pieces partially or completely quilled, of various sizes, from a few inches to two feet in length, from half a line to two or even three lines in thickness, and in the quill from half an inch to an inch and a half in diameter.

Properties. Canella has a pale orange-yellow colour usually lighter on the inner surface, an aromatic odour somewhat resembling that of cloves, and a warm, bitterish, very pungent taste. It is brittle, breaking with a short fracture, and yielding when pulverized a yellowish-white powder. Boiling water extracts nearly one-fourth of its weight; but the infusion, though bitter, has comparatively little of the warmth and pungency of the bark. It yields all its virtues to alcohol, forming a bright yellow tincture, which is rendered milky by the addition of water. By distillation with water it affords a large proportion of a yellow or reddish, fragrant, and very acrid essential oil. It contains, moreover, according to the analysis of MM. Petroz and Robinet, a saccharine substance resembling mannite, a peculiar very bitter extractive, resin, gum, starch, albumen, and various saline substances in small proportion. Canella has been sometimes confounded with Winter's bark, from which, however, it differs both in sensible properties and composition. It contains, for instance, no tannin nor oxide of iron, both of which are ingredients in the latter. (See *Wintera.*)

Medical Properties and Uses. Canella is possessed of the ordinary properties of the aromatics, acting as a local stimulant, and gentle tonic, and producing upon the stomach a warming cordial effect, which renders it useful as an addition to tonic or purgative medicines in debilitated states of the digestive organs. It is scarcely ever prescribed except in combination. In the West Indies it is employed by the negroes as a condiment, and has some reputation as an antiscorbutic.

"Cantharis vesicatoria, *Olivier;* Meloë vesicatorius, *Linn.;* Lytta vesicatoria, *Fabricius.*" *U.S.*

Off. Syn. CANTHARIS. Cantharis vesicatoria. *Lond.;* CANTHARIS VESICATORIA. *Ed.*, *Dub.*

Cantharide, *Fr.;* Spanische Fliege, Kantharide, *Germ.;* Cantarelle, *Ital.;* Cantharidas, *Span.*

The term *cantharis* was employed by the ancient Greek writers to designate many coleopterous insects. Linnæus conferred the title upon a genus in which the officinal blistering fly was not included, and placed this insect in the genus *Meloë.* This latter, however, has been divided by subsequent naturalists into several genera. Geoffroy made the Spanish fly the prototype of a new one which he called *Cantharis,* substituting *Cicindela* as the title of the Linnæan genus which he had thus deprived of its original designation. Fabricius made some alteration in the arrangement of Geoffroy, and substituted *Lytta* for *Cantharis* as the generic title. The former was adopted by the London College, and at one time was in extensive use; but the latter having been restored by Latreille, is now recognised in the European and American Pharmacopœias, and is universally employed. By this naturalist the vesicating insects were grouped in a small tribe corresponding very nearly with the Linnæan genus Meloë, and distinguished by the title *Cantharideæ.* This tribe he divided into eleven genera, among which is the Cantharis. Two others of these genera, the *Meloë* properly so called, and the *Mylabris,* have been employed as vesicatories. The *Mylabris cichorii* is thought to be one of the insects described by Pliny and Dioscorides under the name of cantharides; and is to this day employed in Italy, Greece, the Levant, and Egypt: and another species, the *M. pustulata,* is applied to the same purpose in China. The *Meloë proscarabæus* and the *M. majalis* have been occasionally substituted for cantharides in Europe, and the *M. trianthemæ* is used to a considerable extent in the upper provinces of Hindostan. Several species of Cantharis, closely analogous to each other in medical properties, are found in various parts of the world; but the *C. vesicatoria* is the only one recognised by the Pharmacopœias of France and Great Britain. The *C. vittata* has been introduced into that of the United States, and will be noticed under a distinct head. At present we shall confine our observations to the *C. vesicatoria* or common Spanish fly.

CANTHARIS. *Class* Insecta, *Order* Coleoptera, *Linn.; Family* Trachelides, *Tribe* Cantharideæ, *Latreille.*

Gen. Ch. *Tarsi* entire; *nails* bifid; *head* not produced into a rostrum; *elytra* flexible, covering the whole abdomen, linear, semicylindric; *wings* perfect; *maxillæ* with two membranaceous *laciniæ,* the external one acute within, subuncinate; *antennæ* longer than the head and thorax, rectilinear; first joint largest, the second transverse, very short; *maxillary palpi* larger at tip. *Say.*

Cantharis Vesicatoria. Latreille, *Gen. Crust. et Insect. tom.* ii. *p.* 220. This insect is from six to ten lines in length, by two or three in breadth, and of a beautiful shining golden-green colour. The head is large and heart-shaped, bearing two thread-like, black, jointed feelers; the thorax short and quadrilateral; the wing-sheaths long and flexible, covering brownish membranous wings. When alive, the Spanish flies have a strong, penetrating, fetid odour, compared to that of mice, by which swarms of them may be detected at a considerable distance. They attach themselves preferably to certain trees and shrubs, such as the white poplar, privet, ash, elder, and lilac, upon the leaves of which they feed. The countries in which they most abound are Spain, Italy, and the South of France; but they are found to a greater or less extent in all the temperate parts of Europe, and probably also in the West of Asia. In the state of larva, they live in the ground and gnaw the roots of plants. They usually make their appearance in swarms upon the trees in the months of May and June, at which period they are collected. The time preferred for the purpose is in the morning at sun-rise, when they are torpid from the cold of the night, and easily let go their hold. Persons with their faces protected by masks and their hands by gloves, shake the trees, or beat them with poles; and the insects are received as they fall upon linen cloths spread underneath. They are then plunged into vinegar diluted with water, or exposed in sieves to the vapour of boiling vinegar, and having been thus deprived of life, are dried either in the sun, or in apartments heated by stoves. This mode of killing the flies by the steam of vinegar is as ancient as the times of Dioscorides and Pliny. In some places they are gathered by smoking the trees with burning brimstone. When perfectly dry, they are introduced into casks or boxes, lined with paper and carefully closed, so as to exclude as much as possible the atmospheric moisture.

Cantharides come chiefly from Spain, Italy, and other parts of the Mediterranean. Considerable quantities are also brought from St. Petersburg, derived originally, in all probability, from the southern provinces of Russia. Dr. A. T. Thomson states that they are imported into England "chiefly from Astracan, packed in casks and small chests." They are sometimes mixed with considerable quantities of the *Melolontha vitis*, which, as it is destitute of vesicatory properties, should be separated from the genuine flies. This insect is distinguishable by its almost square form, and by its black feet.

Properties. Dried Spanish flies preserve the form and colour, and, to a certain extent, the disagreeable odour of the living insect. They have an acrid, burning, and urinous taste. Their powder is of a grayish-brown colour, interspersed with shining particles, which are the fragments of the feet, head, and wing-cases. If kept perfectly dry, in well-stopped glass bottles, they will retain their activity for a great length of time. A portion which had been preserved by Van-Swieten for thirty years in a glass vessel, was found still to possess vesicating properties. But exposed to a damp air, they quickly undergo putrefaction; and this change takes place most speedily in the powder; hence the insects should always be kept whole, and powdered only as they are wanted for use. They should never be purchased in powder, as, independently of the consideration just mentioned, they may in this state be more easily adulterated. But, however carefully managed, cantharides are apt to be attacked by mites, which feed on the interior soft parts of the body, reducing them to powder, while the harder exterior parts are not affected. An idea was at one time prevalent, that the vesicating property of the insect was not injured by the worm, which was supposed to devour only the inactive portion. But this has been proved to be a mistake. M. Farines, an apothecary of Perpignan, has satisfactorily shown, that though the hard parts left by these mites possess some vesicating power, and the powder produced by them still more, yet the sound flies are much stronger than either. Camphor, which has been recommended as a preservative, does not prevent the destructive agency of the worm.* It is also stated by M. Farines, that when the flies are destroyed by the vapour of pyroligneous acid instead of common vinegar, they acquire an odour which contributes to their preservation. Cantharides will bear a very considerable heat without losing the brilliant colour of their elytra; nor is this colour extracted by water, alcohol, ether, or the oils; so that the powder might be deprived of all its active principles, and yet retain the exterior characters unaltered.

---

* It appears from the experiments of M. Nivet, that though camphor does not preserve the entire fly from the attacks of the larvæ of the *Anthrenus*, it actually destroys the mites of the Cantharis so often found in the powder, and may, therefore, be introduced with advantage, in small lumps, into bottles containing powdered cantharides. *Journ. de Pharm.* xix. 604.

So early as 1778, Thouvenel attempted to analyze cantharides, and the attempt was repeated by Dr. Beaupoil in 1803; but no very interesting or valuable result was obtained till the year 1810, when Robiquet discovered in them a crystalline substance, which appears to be the vesicating principle of the insect, and to which Dr. Thomson has given the name of *cantharidin.* The constituents, according to Robiquet, are, 1. a green oil, insoluble in water, soluble in alcohol, and inert as a vesicatory; 2. a black matter, soluble in water, insoluble in alcohol, and inert; 3. a yellow viscid matter, soluble in water and alcohol, and without vesicating powers; 4. *cantharidin;* 5. a fat matter insoluble in alcohol; 6. phosphates of lime and of magnesia, acetic acid, and in the fresh insect a small quantity of uric acid. Orfila has since discovered a volatile principle, upon which the fetid odour of the fly depends. It is separable by distillation with water. *Cantharidin* is a white substance in the form of crystalline scales, of a shining micaceous appearance, insoluble in water and cold alcohol; but soluble in ether, the oils, and in boiling alcohol which deposites it upon cooling. It is obtained by submitting the watery extract of cantharides to the action of boiling alcohol, which extracts the yellow matter and the cantharidin. The alcoholic solution is evaporated, and the residue treated repeatedly with sulphuric ether, which dissolves the cantharidin with a small quantity of the yellow matter, and deposites them when allowed to evaporate spontaneously. The yellow matter is separated by cold alcohol; and the cantharidin being thus left pure, is dried between folds of bibulous paper.* Notwithstanding the insolubility of this principle in water and cold alcohol, the decoction and tincture of cantharides have the peculiar medicinal properties of the insect; and Lewis ascertained that both the aqueous and alcoholic extracts acted as effectually in exciting vesication as the flies themselves, while the residue was in each case inert. The cantharidin consequently exists in the insect so combined with the yellow matter as to be rendered soluble in water and cold alcohol.

Medical Properties and Uses. Internally administered, cantharides are a powerful stimulant, exercising a peculiar influence over the urinary and genital organs. In moderate doses, this medicine sometimes acts as a diuretic, and generally excites some irritation in the urinary passages, which, if its use be persevered in, or the dose increased, often amounts to violent strangury, attended with excruciating pain, and the discharge of bloody urine. In still larger quantities, it produces, in addition to these effects, obstinate and painful priapism, vomiting, bloody stools, severe pains in the whole abdominal region, with a fetid cadaverous breath, hurried respiration, a hard and frequent pulse, burning thirst, sometimes a dread of liquids, frightful convulsions, tetanus, delirium, and death. Dissection reveals inflammation and ulceration of the mucous coat of the whole intestinal canal. Notwithstanding their exceeding violence, cantharides have been long and beneficially used in medicine. They appear to have been given by Hippocrates in cases of dropsy and amenorrhœa, in the latter of which complaints, when properly prescribed, they are a highly valuable remedy. In dropsy they sometimes prove beneficial when the system is in an atonic condition, and the vessels of the kidneys feeble. Dr. Ferriar considers them peculiarly useful in the anasarcous swellings which occasionally succeed scarlet fever. They are also useful in obstinate gleet, leucorrhœa, and seminal weakness; and afford one of the most certain means of relief in incontinence of urine arising from debility or partial paralysis of the sphincter of the bladder. A case of diabetes is recorded in the N. Am. Archives, (vol.ii. p. 175,) in whicha cure was effected under the use of tincture of cantharides. Their unpleasant effects upon the urinary passages are best obviated by the free use of diluent drinks; and, when not consequent upon great abuse of the medicine, may almost always be relieved by an anodyne injection composed of laudanum with a small quantity of mucilaginous fluid. The dose of Spanish flies is one or two grains of the powder, which may be given twice a day in the form of pill. The tincture, however, is more frequently employed.

---

* In the *Journal de Pharmacie* for January, 1835, a much simpler and more productive method of obtaining cantharidin is described by M. Thierry. It consists in macerating powdered flies in ether for several days; introducing the mixture into an apparatus for filtering by displacement; adding, after the liquid has ceased to flow out, fresh portions of ether, till it comes away nearly colourless; displacing the whole of the menstruum still remaining in the mass by pouring water upon it; distilling the filtered liquor so as to recover the ether; then allowing the residue to cool; and finally purifying the cantharidin which is deposited, by treating it with boiling alcohol and animal charcoal. Alcohol of 34°, or a mixture of alcohol and ether, may be substituted for the ether itself; but the last mentioned fluid is preferable, as it dissolves less of the green oil, the separation of which from the cantharidin is the most difficult part of the process. M. Thierry obtained from 1000 parts of powdered flies, 4 parts of pure cantharidin.

Externally applied, cantharides excite inflammation in the skin, which terminates in a copious secretion of serum under the cuticle. Even thus applied, they not unfrequently give rise to strangury or tenesmus; and this in fact is one of the most troublesome attendants upon their operation. It probably results from the absorption of the active principle of the fly; and is not prevented by any of the various modes of combination in which the epispastic substance has been applied. Camphor given internally, or mixed with the flies previously to their application, was at one time in much repute as a preventive of strangury; but has lost its credit. The most certain method of obviating this unpleasant effect, is to allow the epispastic application to continue no longer than is necessary to its full rubefacient operation; and afterwards to favour vesication by the use of an emollient poultice. (See *Ceratum Cantharidis.*)

The blistering fly may be employed either as a rubefacient, or with a view to the production of a blister. In the former capacity it is seldom used, except in low states of disease, where external stimulation is required to support the system; but as an epispastic, it is preferred to all other substances, and in the extent of its employment is surpassed by few articles of the materia medica.

Blisters are calculated to answer numerous indications. Their local effect is attended with a general excitement of the system, which renders them valuable auxiliaries to internal stimulants in low or typhoid conditions of disease; and they may sometimes be safely resorted to with this view when the latter remedies are inadmissible. The powerful impression they make on the system is sufficient in many instances to subvert morbid associations, and thus to allow the re-establishment of healthy action. Hence their application to the cure of remittent and intermittent fevers, in which they often prove effectual, when so employed as to be in full operation at the period for the recurrence of the paroxysm. On the principle of revulsion, they prove useful in a vast variety of complaints. Drawing both the nervous energy and the circulating fluid to the seat of their own immediate action, they relieve irritations and inflammations of internal parts; and are employed for this purpose in every disease attended with these derangements. In such cases, however, arterial excitement should always be reduced by direct depletion before the remedy is resorted to. Blisters are also capable of substituting their own action for one of a morbid nature existing in the part to which they are directly applied. Hence their use in tinea capitis, obstinate herpes, and various cutaneous eruptions. Their local stimulation renders them useful in some cases of threatened gangrene, and in partial paralysis. From the serous discharge they occasion, much good results in erysipelas and various other local inflammations, in the immediate vicinity of which their action can be established; and the effects of an issue may be obtained by the continued application of irritants to the blistered surface. Perhaps the pain produced by blisters may be useful in some cases of nervous excitement or derangement, in which it is desirable to withdraw the attention of the patient from subjects of agitating reflection. On some constitutions they produce a poisonous impression, attended with frequent pulse, dryness of the mouth and fauces, heat of skin, subsultus tendinum, and even convulsions; and some physicians have been so much alarmed by the occasional occurrence of these symptoms as to induce them to employ the remedy with great hesitation. What is the precise condition of system in which these effects result, it is impossible to determine. They probably arise from the absorption of the active principle of cantharides; and depend on idiosyncrasies of constitution, by which the system of certain individuals is susceptible of impressions different from those usually produced by the same cause. In this respect the Spanish flies are analogous to mercury; and any argument drawn from this source against the use of the one would equally apply to the other. The general good which results from their use far overbalances any partial and uncertain evil. For some rules relative to the application of blisters, the reader is referred to the *Ceratum Cantharidis.*

CANTHARIS VITTATA. *U.S.*

Potato Flies.

"Cantharis vittata, *Olivier;* Lytta vittata, *Fabricius.*" *U. S.*

Within the limits of the United States are several species of Cantharis, which have been employed as substitutes for the C. vesicatoria, and found to be equally efficient. Of these only the *C. vittata* has been adopted as officinal; but as others may be more abundant in particular districts, or in certain seasons, and are not inferior in vesicating powers, we shall briefly notice all which have been submitted to experiment.

1. *Catharis vittata.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 4. The *potato fly* is rather smaller than the *C. vesicatoria*, which it resembles in shape. Its length is about six lines. The head is of a light red colour, with dark spots upon the top; the feelers are black; the elytra or wing cases are black, with a yellow longitudinal stripe in the centre, and with a yellow margin; the thorax is also black, with three yellow lines; and the abdomen and legs, which have the same colour, are covered with a cinereous down. It inhabits chiefly the potato vine, and makes its appearance about the end of July or beginning of August, in some seasons, in great abundance. It is found on the plant in

the morning and evening; but during the heat of the day descends into the soil. The insects are collected by shaking them from the plant into hot water; and are afterwards carefully dried in the sun. They are natives of the Middle and Southern States.

This species of Cantharis was first described by Fabricius in the year 1781; and was introduced to the notice of the profession by Dr. Isaac Chapman of Bucks county, Pennsylvania, who found it equal if not superior to the Spanish fly as a vesicatory. The testimony of Dr. Chapman has been corroborated by that of many other practitioners, some of whom have even gone so far as to assert, that the potato fly is not attended in its action with the inconvenience of producing strangury. But this statement has been ascertained to be incorrect; and as the vesicating property of all these insects probably depends upon the same proximate principle, their operation may be considered as identical in other respects. If the potato fly has been found more speedy in its effects than the Cantharis of Spain, the result is perhaps attributable to the greater freshness of the former. It may be applied to the same purposes, treated in the same manner, and given in the same dose as the foreign insect.

2. *Cantharis cinerea.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 5. The *ash-coloured cantharis* closely resembles the preceding species in figure and size; but differs from it in colour. The elytra and body are black, without the yellow stripes that characterize the C. vittata, and are entirely covered with a short and dense ash-coloured down, which conceals the proper colour of the insect. The feelers are black, and the first and second joints are very large in the male. This species also inhabits the potato-vine, and is occasionally found on other plants, as the English bean and wild indigo. It is a native of the Northern and Middle States. All the remarks before made upon the potato fly, as to the mode of collection, properties, and medical use, apply equally well to that at present under consideration. Illiger in 1801 first discovered its vesicating properties; but to Dr. Gorham is due the credit of calling public attention particularly to the subject, in a communication addressed, in the year 1808, to the Medical Society of Massachusetts. This species is often confounded with the *C. vittata.*

3. *Cantharis marginata.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 6. This is somewhat larger than the *C. vittata,* and of a different shape. The elytra are black, with the suture and margin ash-coloured. The head, thorax, and abdomen are black, but nearly covered with an ash-coloured down; and on the upper part of the abdomen, under the wings, are two longitudinal lines of a bright clay colour. This species is usually found, in the latter part of summer, upon the different plants belonging to the genus *Clematis,* and frequents especially the lower branches which trail along the ground. Professor Woodhouse of Philadelphia first ascertained the vesicating properties of this insect; but it had previously been described by Fabricius as a native of the Cape of Good Hope. Dr. Harris, of Massachusetts, found it equally efficient as a vesicatory with any other species of this genus.

4. *Cantharis atrata.* Latreille, *Gen. Crust. et Insect.;* Durand, *Journ. of the Phil. Col. of Pharm.* ii. 274. fig. 7. The *black cantharis* is smaller than the indigenous species already described; but resembles the *C. marginata* in figure. Its length is only four or five lines. It is distinguished by its size, and by its uniform black colour. It frequents more especially the different species of *Aster* and *Solidago,* though it is found also on the *Prunella vulgaris, Ambrosia trifida,* and some other plants. Mr. Durand met

with considerable numbers of this insect in the neighbourhood of Philadelphia in the month of September, and they continued to appear till the middle of October. They are common in the Northern and Middle States, but are not confined exclusively to this country, being found also in Barbary. Drs. Oswood and Harris of New-England have experimented with them, and satisfactorily ascertained their vesicating powers. They are probably identical with the insect noticed as vesicatory by Professor Woodhouse, under the name of *Meloë niger*.

Several other species have been discovered in the United States, but not yet practically employed. Among these are the *C. æneas*, a native of Pennsylvania, discovered by Mr. Say; the *C. politus* and *C. aszelianus*, which inhabit the Southern States; the *C. Nuttalli*, a large and beautiful insect of Missouri, first noticed by Mr. Nuttall, and said to surpass the Spanish fly in magnitude and splendour; and the *C. albida*, another large species, found by Mr. Say near the Rocky Mountains. Of these, the *C Nuttalli** bids fair, at some future period, to be an object of some importance in the western section of this country. The head is of a deep greenish colour, with a red spot in front; the thorax is of a golden green; the elytra, red or golden purple and somewhat rugose on their outer surface, green and polished beneath; the feet, black; the thighs, blue or purplish. The exploring party under Major Long ascertained the vesicating powers of this insect. It was found in the plains of the Missouri, feeding on a scanty grass, which it sometimes covered to a considerable extent. In one place it was so numerous and troublesome, as to be swept away by bushels, in order that a place might be cleared for encamping. W.

CAPSICUM. *U.S.*

Cayenne Pepper.

"Capsicum annuum. Fructus. *The fruit.*" *U.S.*

Off. Syn. CAPSICI BACCÆ. Capsicum annuum. Baccæ. *Lond.;* CAPSICI ANNUI FRUCTUS. *Ed.;* CAPSICUM ANNUUM. Capsulæ cum seminibus. *Dub.*

Poivre de Guinée, Poivre d'Inde, *Fr.;* Spanischer Pfeffer, *Germ.;* Pepperone, *Ital.;* Pimiento, *Span.*

Capsicum. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ.

Gen. Ch. Corolla wheel-shaped. *Berry* without juice. *Willd.*

Numerous species of Capsicum, inhabiting the East Indies and tropical America, are enumerated by botanists, the fruit of which, differing simply in the degree of pungency, may be indiscriminately employed. The *C. baccatum* or bird pepper, and the *C. frutescens* are said to yield most of the Cayenne pepper brought from the West Indies and South America; and Ainslie informs us that the latter is chiefly employed in the East Indies. The species most extensively cultivated in Europe and this country, is that recognised as officinal by the Pharmacopœias; namely, the *C. annuum.* The first two are shrubby plants, the last is annual and herbaceous.

Capsicum annuum. Willd. *Sp. Plant.* i. 1050; Woodv. *Med. Bot.* p. 226. t. 80. The stem of the annual capsicum is thick, roundish, smooth, and branching; rises two or three feet in height; and supports ovate, pointed,

---

* *Lytta Nuttalli*, Say, Amer. Entomol. vol. i. fig. 3.

smooth, entire leaves, which are placed without regular order on long footstalks. The flowers are solitary, white, and stand on long peduncles at the axils of the leaves. The calyx is persistent, tubular, and five-cleft; the corolla, monopetalous and wheel-shaped, with the limb divided into five spreading, pointed, and plaited segments; the filaments, short, tapering, and furnished with oblong anthers; the germen, ovate, supporting a slender style which is longer than the filaments, and terminates in a blunt stigma. The fruit is a pendulous, pod-like berry, light, smooth and shinning, of a bright scarlet, orange, or sometimes yellow colour, with two or three cells, containing a dry loose pulp, and numerous flat, kidney-shaped, whitish seeds.

The plant is a native of the warmer regions of Asia and America, and is cultivated in almost all parts of the world. It is abundantly produced in this country, both for culinary and medicinal purposes. The flowers appear in July and August, and the fruit ripens in October. Several varieties are cultivated in our gardens, differing in the shape of the fruit. The most abundant is probably that with a large irregularly ovate berry, depressed at the extremity, which is much used in the green state for pickling. The medicinal variety is that with long, conical, generally pointed, recurved fruit, usually not thicker than the finger. Sometimes we meet with small, spherical, slightly compressed berries, not greatly exceeding a large cherry in size. When perfectly ripe and dry, the fruit is ground into powder, and brought into market under the name of red or Cayenne pepper. Our markets are also partly supplied by importation from the West Indies. A variety of capsicum, consisting of very small conical, exceedingly pungent berries, has recently been imported from Liberia.

Powdered capsicum is usually of a more or less bright red colour, which fades upon exposure to light, and ultimately disappears. The odour is peculiar and somewhat aromatic, stronger in the recent than in the dried fruit. The taste is bitterish, acrid, and burning, producing a fiery sensation in the mouth, which continues for a long time. The pungency appears to depend on a peculiar principle, which was obtained, though probably not in a perfectly isolated state, by Braconnot, and named *capsicin*. The fruit, freed from the seeds, was submitted to the action of alcohol, and the resulting tincture evaporated. During the evaporation a red-coloured wax separated, and the residuary liquor by further evaporation afforded an extract, from which ether dissolved the capsicin. This was obtained by evaporating the ether. It resembles an oil or soft resin, is of a yellowish-brown or reddish-brown colour, and when tasted, though at first balsamic, soon produces an insupportably hot and pungent impression over the whole interior of the mouth. Exposed to heat it melts, and at a higher temperature, emits fumes which, even in very small quantity, excite coughing and sneezing. It is slightly soluble in water and vinegar, and very soluble in alcohol, ether, oil of turpentine, and the caustic alkalies, which it renders reddish-brown. It constitutes, according to Braconnot, 1.9 per cent. of the pods. The other ingredients, as ascertained by the same chemist, are colouring matter, an azotized substance, gum, pectic acid (probably pectin), and saline matters. Duncan states that the active principle of capsicum is precipitated by infusion of galls, nitrate and muriate of mercury, nitrate of silver, sulphate of copper, sulphate of zinc, persulphate of iron, ammonia, carbonate of potassa, and alum. Precipitates may be produced with the infusion of capsicum by these substances; but it is by no means certain that they all throw down the active principle. It is said that the red oxide of lead is sometimes added to the powdered capsicum sold in Europe. It may be detected by digesting the suspected powder in diluted nitric acid, filtering, and adding a solution of sulphate of soda, which will throw down a white precipitate if there be any oxide of lead present.

Medical Properties and Uses. Cayenne pepper is a powerful stimulant, producing when swallowed a sense of heat in the stomach, and a general glow over the body, without any narcotic effect. Its influence over the circulation, though considerable, is not in proportion to its local action. It is much employed as a condiment, and proves highly useful in correcting the flatulent tendency of certain vegetables, and bringing them within the digestive powers of the stomach. Hence the advantage derived from it by the natives of tropical climates who live chiefly on vegetable food. In the East Indies it has been used from time immemorial. From a passage in the works of Pliny, it appears to have been known to the Romans. As a medicine it is useful in cases of enfeebled and lanquid stomach; and is occasionally prescribed in dyspepsia and atonic gout, particularly when attended with much flatulence, or occurring in persons of intemperate habits. It has also been given as a stimulant in palsy and certain lethargic affections. To the sulphate of quinia it forms an excellent addition in some cases of intermittents, in which there is great want of gastric susceptibility. It acts by exciting the stomach, and rendering it sensible to the influence of the tonic. Upon the same principle it may prove useful in low forms of fever as an adjuvant to tonic or stimulant medicines. Its most important application, however, is to the treatment of malignant sore throat and scarlet fever, in which it is used both internally and as a gargle. No other remedy has obtained equal credit in these complaints. The following formula was employed in malignant scarlatina with great advantage in the West Indies, where this application of the remedy originated. Two tablespoonfuls of the powdered pepper with a teaspoonful of common salt are infused for an hour in a pint of a boiling liquid, composed of equal parts of water and vinegar. This is strained when cool through a fine linen cloth, and given in the dose of a tablespoonful every half hour. The same preparation is also used as a gargle. It is, however, only to the worst cases that the remedy is applied so energetically. In milder cases of scarlatina with inflamed or ulcerated throat, much relief and positive advantage often follow the employment of the pepper in a more diluted state.

Applied externally, capsicum is a powerful rubefacient, very useful in local rheumatism, and in low forms of disease, where a stimulant impression upon the surface is demanded. It has the advantage, under these circumstances, of acting speedily without endangering vesication. It may be applied in the form of cataplasm, or more conveniently and efficiently as a lotion mixed with heated spirit. The powder or tincture, brought into contact with a relaxed uvula, often acts very beneficially.

The dose of the powder is from five to ten grains, which may be most conveniently given in the form of pill. Of an infusion prepared by adding two drachms to half a pint of boiling water, the dose is about half a fluidounce. A gargle may be prepared by infusing half a drachm of the powder in a pint of boiling water, or adding half a fluidounce of the tincture to eight fluidounces of rose-water.

CARBO.

Carbon.

Pure charcoal; Carbone, *Fr., Ital.;* Kohlenstoff, *Germ.;* Carbon, *Span.*

Carbon is an elementary combustible substance of great importance, and very extensively diffused in nature. It exists in large quantity, under various forms and in different states of combination, in the mineral kingdom; and it forms the most abundant constituent of animal and vegetable matter. In a state of perfect purity and crystallized, it constitutes the diamond, and more or less pure, it forms the substances known under the names of *plumbago* or *black lead*, *anthracite*, *bituminous coal*, *coke*, *animal charcoal*, and *vegetable charcoal.* Combined with oxygen, it constitutes *carbonic acid*, which is an invariable constituent of the atmosphere, and is present in many natural waters, especially those which have an effervescing quality. United with oxygen and a base, it forms the carbonates, and of course *carbonate of lime*, which is one of the most abundant combinations of the mineral kingdom.

The *diamond*, or crystallized carbon, is found principally in India and Brazil. It is perfectly transparent, and is the hardest and most brilliant substance in nature. On account of these properties, as well as its great rarity and durability, it is exceedingly precious. Its sp. gr. is about 3.5. It is perfectly fixed and unalterable in the fire, provided air be completely excluded; but it is combustible in air or oxygen, the product being the same as when charcoal is burnt, namely carbonic acid.

Next to diamond, plumbago and anthracite are the purest natural forms of carbon. Plumbago is the substance of which black lead crucibles and pencils are made. It is found in greatest purity, perhaps, in the mine of Borrowdale, in England; but it also occurs very pure in this country, especially near Bustleton in Pennsylvania. It was formerly supposed to be a carburet of iron; but in very pure specimens it is nearly free from iron, which must, therefore, be deemed merely an accidental impurity. Anthracite is a pretty abundant form of mineral carbon. It occurs in different parts of the world, but particularly in the United States. Immense beds of it exist in the interior of Pennsylvania, in Rhode Island, and on the banks of the Arkansas. Bituminous coal is a form of the carbonaceous principle, in which the carbon is associated with volatile matter of a bituminous nature. When this is driven off by the process of charring, a kind of mineral charcoal called coke is obtained, very useful in the arts as a fuel.

Carbon may be obtained artificially, in a state approaching to purity, by several processes. One method is to expose lampblack to a full red heat in a close vessel. It may also be obtained in a very pure state by passing the vapour of volatile oils through an ignited porcelain tube, whereby the hydrogen and oxygen of the oil will be dissipated, and the charcoal left in the tube. A very pure charcoal is procured by exposing sugar, or other vegetable substances which leave no ashes when burnt, to ignition in close vessels.

Properties. Carbon in its crystallized form has already been described as diamond. In its uncrystallized state it is an insoluble, infusible* solid, generally of a black colour, and without taste or smell. It is combustible, and when sufficiently heated unites with the oxygen of the air, and generates a gaseous acid, called carbonic acid. Its sp. gr. in the solid state, apart from the pores which it contains when in mass, is 3.5; but with the pores included, it is only 0.44. In a state of vapour, its density is 0.4215, as obtained by calculation. It is a very unalterable and indestructible substance, and has great power to resist and correct putrefaction in other bodies. When in a state of extreme division, it possesses the remarkable property of destroying the colouring and odorous principles of most liquids. The conditions, under which this property is most powerfully developed, will be explained under the head of animal charcoal. (See *Carbo Animalis.*) Its other physical properties differ according to its source and peculiar state of aggregation. Its equivalent number is 6.12. As a chemical element, it enjoys a very extensive range of combination. It combines in five proportions with oxygen, forming carbonic oxide, and carbonic, oxalic, mellitic, and croconic acids. (See *Aqua Acidi Carbonici*, and *Oxalic Acid.*) It unites also with chlorine, iodine, and bromine. With hydrogen it forms many combinations, amongst which the most interesting and best known are light carburetted hydrogen or fire-damp, and olefiant gas. With nitrogen it constitutes cyanogen, the compound radical of hydrocyanic or prussic acid; and united with iron in minute proportion it forms steel. It is thus perceived, that as a chemical agent it performs a most important part in the economy of nature.

---

* Professor Silliman, however, is of opinion that it is fusible when subjected to the intense ignition produced by the galvanic deflagrator of Dr. Hare; and Dr. Colquhoun

To notice all the forms of the carbonaceous principle would be out of place in this work. We shall, therefore, restrict ourselves to the consideration of those which are officinal, namely, *animal charcoal*, and common *wood charcoal;* and these will be described in the two following articles.

B.

CARBO ANIMALIS. *U.S.*

Animal Charcoal.

Charbon animal, *Fr.;* Thierische Kohle, *Germ.;* Carbone animale, *Ital.;* Carbon animal, *Span.*

By animal charcoal, in the United States Pharmacopœia, is meant that form of the carbonaceous principle which is obtained from animal substances, and possesses the property of removing colouring matters from solutions. All kinds of animal charcoal do not necessarily possess the decolorizing property, and hence would not be applicable to pharmaceutical purposes. This substance is not officinal in the British Pharmacopœias.

The kind of animal charcoal usually employed in pharmacy and the arts, is obtained from bones, by subjecting them to a red heat in close vessels. The residue of the ignition is a black matter, which when reduced to powder forms the substance properly called *bone-black*, but familiarly known under the incorrect name of *ivory-black.* Ivory by carbonization will furnish a black, which, on account of its fineness and intensely black colour, is more esteemed than the ordinary bone-black; but it is much more expensive.

---

inclines to the opinion that the perfectly pure charcoal deposited from coal gas has undergone fusion.

Animal charcoal, in the form of bone-black, is almost exclusively prepared by the makers of ammoniacal products. Bones are by these manufacturers subjected to destructive distillation in iron retorts or cylinders, and after all the ammoniacal products have come over, the residuum is charred bone, or bone-black. The bone consists of animal matter with phosphate and carbonate of lime. In consequence of a new arrangement of the elements of the animal matter, the hydrogen and nitrogen united as ammonia, and a part of the charcoal as carbonic acid, distil over; while the remainder of the charcoal is left in the retort, intermingled with the calcareous salts. In this form, therefore, of animal charcoal, the carbon is evidently mixed with phosphate and carbonate of lime, and the same is the case with the true ivory-black.

Properties. Animal charcoal, in the form of bone-black, (called ivory-black in the shops,) is a black powder, possessing a slightly alkaline and bitterish taste, and having a general resemblance to powdered vegetable charcoal. It is, however, more dense and less combustible than this charcoal, from which, moreover, it may be distinguished by burning a small portion of it on a red-hot iron, when it will leave a residuum but imperfectly acted on by sulphuric acid; whereas the ashes from vegetable charcoal will readily dissolve in this acid, and form a bitterish solution.

Animal charcoal by no means necessarily possesses the decolorizing property; as this depends upon its peculiar state of aggregation. If a piece of pure animal matter be carbonized, it usually enters into fusion, and from the gaseous matter which is extricated, becomes porous and cellular. The charcoal formed has generally a metallic lustre, and a colour resembling that of black lead. It has, however, little or no decolorizing power, even though it may be finely pulverized.

Pharmaceutical and Economical Uses. Animal charcoal is used in pharmacy for the most part to decolorize vegetable principles, such as quinia, morphia, &c., and in the arts, principally for the purpose of clarifying syrups in sugar refining, and of depriving spirits distilled from grain of the peculiar volatile oil, which imparts to them an unpleasant taste as first distilled. The only formula in which it is used in the United States Pharmacopœia, is that for the preparation of sulphate of quinia. The manner in which it is used is to mix it with the substance to be decolorized, and to allow the mixture to stand for some time. The charcoal unites chemically with the colouring matter, and the solution by filtration is obtained white and transparent. For nice decolorizing operations, the animal charcoal, if bone-black, must be digested in muriatic acid in order to free it from phosphate and carbonate of lime.

Rationale of the effects of Charcoal as a Decolorizing Agent. Under this head we shall speak generally of the conditions necessary to constitute charcoal a decolorizing agent; by which it will more clearly appear why certain animal charcoals possess this property. The decolorizing power of charcoal was first noticed by Lowitz of St. Petersburg; and the subject was subsequently ably investigated by Bussy, Payen, and Desfosses. It is generally communicated to charcoal by igniting it in close vessels, but not always. The kind of charcoal, for example, obtained from substances which undergo fusion during carbonization, does not possess the property, even though it may be afterwards finely pulverized by mechanical means. The property in question is possessed to a certain extent by wood charcoal; but is developed in it in a much greater degree by burning it with some chemical substance, which may have the effect of reducing it to an extreme degree of fineness. The most powerful of all the charcoals for discharging colours, are those obtained from certain animal matters, such as dried blood, hair, horns, hoofs, &c. by first carbonizing them in connexion with carbonate of potassa, and then washing the product with water. Charcoal thus prepared seems to be reduced to its finest possible particles. The next most powerful decolorizing charcoal is *ivory* or *bone-black*, in which the separation of the carbonaceous particles is effected by the phosphate of lime present in the bone. Vegetable substances also may be made to yield a good charcoal for destroying colour, provided before carbonization, they be well comminuted, and mixed with pumice stone, chalk, flint, calcined bones, or other similar substance in a pulverized state.

It results from the foregoing facts, that the decolorizing power of charcoal depends upon a peculiar mode of aggregation of its particles, the leading character of which is that they are isolated, as it were, from one another, and thus enabled to present a greater extent of surface. It is on this principle that certain chemical substances act in developing the property in question, when they are ignited in a state of intimate mixture with the substance to be charred. Thus it is perceived that there is no necessary connexion between animal charcoal and the decolorizing power; as this charcoal may or may not possess the peculiar aggregation of its particles on which the power depends. Bone-black, for instance, has this property, not because it is an animal charcoal; but because, in consequence of the phosphate of lime present in the bone, the favourable state of aggregation is induced. Of all the substances yet tried to insulate the carbonaceous molecules, carbonate of potassa appears to be the best.

Charcoal which has been used for decolorizing, loses its peculiar property, which cannot be restored by a fresh ignition, unless it be previously mixed with some inorganic substance. The best substance for this purpose is carbonate of potassa, which, after the ignition, must be washed away from the charcoal.

The following table, abridged from one drawn up by Bussy, denotes the decolorizing power of different charcoals, compared with the effect of bone-black taken as unity.

KINDS OF CHARCOAL.	*Decolorizing Power relative to Syrup.*	*Decolorizing Power relative to Indigo.*
Bone-black, - - - - - - - - - - - - -	1	1
Bone charcoal treated by an acid, - - - - - - - -	1.6	1.87
Oil ignited with phosphate of lime, - - - - - - -	1.9	2
Lampblack, not ignited, - - - - - - - - - -	3.3	4
Charcoal from acetate of potassa, - - - - - - - -	4.4	5.6
Gluten ignited with the carbonate of potassa, - - - - -	8.8	10.6
Blood ignited with phosphate of lime, - - - - - - -	10	12
Lampblack ignited with the carbonate of potassa, - - - -	10.6	12.2
Blood ignited with chalk, - - - - - - - - - - -	11	18
White of egg ignited with carbonate of potassa, - - - -	15.5	34
Glue ignited with carbonate of potassa, - - - - - - -	15.5	36
Bone charcoal, formed by depriving the bone of phosphate of lime by an acid, and ignition with potassa, - - - - - - -	20	45
Blood ignited with carbonate of potassa, - - - - - - -	20	50

Comparing the extremes of this table, it is perceived that blood ignited with carbonate of potassa is twenty times more powerful in discharging the colour of syrup, and fifty times more powerful in decolorizing indigo, than an equal weight of bone-black. This is certainly a great disparity in effect, and could hardly have been anticipated. B.

CARBO LIGNI. *U.S., Lond., Ed., Dub.*

Charcoal.

Charbon de bois, *Fr.;* Holzkohle, *Germ.;* Carbone di legno, *Ital.;* Carbon de lena, *Span.*

Preparation on the Large Scale. Common charcoal is prepared in the following manner. Billets of wood are piled in a conical heap, and covered with earth and sod to prevent the access of air; several holes being left at the bottom, and one at the top of the heap, in order to produce a draught to commence the combustion. The wood is then kindled from the bottom. In a little while, the hole at the top is closed, and after the ignition has been found to pervade the whole heap, those at the bottom are stopped also. The combustion taking place with a smothered flame and limited access of air, the volatile portions of the wood, consisting of hydrogen and oxygen, are dissipated, while the carbon, in the form of charcoal, is left behind.

In this process for the carbonization of wood, all the volatile products are lost; and a portion of the charcoal itself is dissipated by combustion. Wood thus carbonized, yields not more than 17 or 18 per cent. of charcoal. A better method is to char the wood in iron cylinders, when it yields from 22 to 23 parts in the 100 of excellent charcoal; and at the same time, the means are afforded for collecting the volatile products, consisting of pyroligneous acid, empyreumatic oil, and tar. This process for obtaining charcoal has been described under another head. (See *Acidum Aceticum Empyreumaticum*, U. S.)

Preparation for Medical Use. Common charcoal is not, perhaps, sufficiently pure for medical exhibition; as all the volatile portions of the wood are not completely expelled. Lowitz directs its purification to be conducted in the following manner. Fill a crucible with ordinary charcoal reduced to fine powder, and lute on a perforated cover. Then expose the whole to a strong red heat, and continue the ignition as long as a blue flame issues from the aperture in the cover. When this ceases, allow the charcoal to cool, and transfer it quickly to bottles, which must be well stopped.

The Paris Codex directs the preparation of charcoal for medical use to be conducted as follows. Take any quantity of thoroughly burnt charcoal, very light, sonorous, and pure, made from the wood of the linden-tree, willow, poplar, or some other of the lighter woods, and moisten it with water. Reduce it to powder in an iron mortar, or by means of a mill; and having mixed it with water to form a thin fluid mass, let it stand for a few days; after which, place it on a linen cloth to drain. Make up the paste into round cakes, and expose them to the rays of the sun until they are thoroughly dried. By this process of insolation, the charcoal is stated in the Codex to be completely deprived of all adventitious colour and smell, and to be singularly improved in efficiency; advantages which are not equally obtained, when it is dried in the shade.

Properties. Charcoal is a black, shining, brittle, porous substance, tasteless and inodorous, and insoluble in water. It is a good conductor of electricity, but a bad one of heat. In masses, it floats in water; but when reduced to a fine powder, whereby its porosity is destroyed, it sinks in that liquid. It possesses the remarkable property of absorbing many times its own bulk of certain gases, provided it be perfectly dry. When exposed to the air after ignition, it increases rapidly in weight, absorbing from twelve to fourteen per cent. of moisture. As ordinarily prepared, it contains the incombustible part of the wood, which would have formed the ashes in its ordinary combustion. These amount to about one-fiftieth of the charcoal, and may be removed by digesting it in diluted muriatic acid, and afterwards washing it thoroughly on a filter with boiling water.

Medical Properties, &c. Powdered charcoal is antiseptic and absorbent. It is employed with advantage in certain forms of dyspepsia, attended with fetid breath and putrid eructations, in doses of about ten grains; and it has been exhibited in dysentery with the effect of correcting the fetor of the stools. It has been recommended as a specific in intermittent fever, and for the purpose of obviating costiveness; but its powers in the former disease are not well established. As a remedy in obstinate constipation, Dr. Daniel of Savannah speaks of it in high terms, and reports fourteen or fifteen cases as occurring in his practice, in which it proved successful. He also found it a useful remedy in the nausea and confined state of the bowels, which usually attend pregnancy. Mixed with crum of bread or linseed meal and water, into the consistence of a cataplasm, it forms a good application to gangrene and ill-conditioned ulcers; and the Dublin College has an officinal preparation of this kind. Mr. Pearson, a distinguished surgeon of London, employed it advantageously as a topical application in traumatic hemorrhage, and states that he believes it to be the basis of Ruspini's styptic. Several of its varieties constitute the best tooth-powder which can be used. Those which are generally preferred are the charcoals of the cocoa-nut shell and of bread. The dose of charcoal varies from ten grains to a drachm or more. Dr. Daniel gave it in his cases, in doses of a tablespoonful repeated every half hour.

In consequence of the absorbent and antiseptic properties of charcoal, it is invaluable in domestic economy. Meat embedded in it in close vessels is kept perfectly sweet for many months; and water intended for long voyages is equally preserved by the addition of its powder. The power of some of its varieties in destroying colours and odours is very considerable; and it acts upon the principle which has been explained under the head of animal charcoal. (See *Carbo Animalis.*)

Cresson des prés, *Fr.;* Wiesenkresse, *Germ.;* Kardamine, *Ital.*

CARDAMINE. *Sex. Syst.* Tetradynamia Siliquosa.—*Nat. Ord.* Cruciferæ.

Gen. Ch. Pods opening elastically, with revolute valves. *Stigma* entire. *Calyx* somewhat gaping. *Willd.*

Cardamine pratensis. Willd. *Sp. Plant.* iii. 487; Woodv. *Med. Bot.* p. 398. t. 144. The Cuckoo-flower is a perennial herbaceous plant, with a simple, smooth, erect stem, about a foot in height. The leaves are pinnate; the radical, composed of roundish irregularly toothed leaflets, those of the stem alternate, with leaflets which become narrower, more entire, and pointed as they ascend. The flowers are purplish-white or rose-coloured, and terminate the stem in a raceme approaching the character of a corymb.

This species of Cardamine is a native of Europe, and is found in the northern parts of our continent, about Hudson's Bay. It is a very handsome plant, abounding in moist meadows, which it adorns with its flowers in the months of April and May. The leaves are bitterish and slighly pungent, resembling in some measure those of water-cresses, and like them supposed to be possessed of antiscorbutic properties. In Europe they are sometimes added to salads. The flowers only are officinal. They have the same taste with the leaves, and, when fresh, a somewhat pungent odour. When dried, they become inodorous and nearly insipid.

They formerly possessed the reputation of being diuretic, and since the publication of a paper by Sir George Baker, somewhat more than half a century ago, have been occasionally used as an antispasmodic in various nervous diseases, such as chorea and spasmodic asthma, in which they were successfully employed by that physician. They produce, however, little obvious effect upon the system, and are not employed in this country.

W.

CARDAMOMUM. *U.S.*

Cardamom.

"Matonia Cardamomum. *Roscoe.* Elettaria Cardamomum. *Maton.* Semina. *The seeds.*" *U. S.*

Off. Syn. CARDAMOMI SEMINA. Matonia Cardamomum. Semina. *Lond.;* AMOMI REPENTIS SEMINA. *Ed.;* AMOMUM CARDAMOMUM. Semina. *Dub.*

Petit cardamome, *Fr.;* Kleine Kardamomen, *Germ.;* Cardamomo minore, *Ital.;* Cardamomo menor, *Span.;* Ebil, *Arab.;* Kakeleh seghar, *Persian;* Capalaga, *Malay;* Gujarati elachi, *Hindoost.*

The name *cardamom* has been applied to the aromatic capsules of various Indian plants belonging to the family of the Scitamineæ. Three varieties have long been known under the distinctive titles of lesser, middle, and larger —the *cardamomum minus*, *medium*, and *majus*, of older writers. Of these, the first only is recognised by the Pharmacopœias, or generally kept in the shops. The *middle cardamoms*, which are longer than the *lesser*, but not so thick, are of unknown origin, being considered by some as derived from the same plant with the first variety, by others as identical with the third, and differing in size only in consequence of having been collected at a different stage of maturity. The *larger* greatly exceed the others in dimensions, being sometimes an inch and a half long, by one quarter of an inch in thickness. They are generally ascribed to the *Amomum Cardamomum* of Willdenow, which grows in Malacca, Java, and other Malay islands. We find also described by writers on the materia medica, the *round cardamoms* and the *long cardamoms;* but of these the first may without violence be joined with the *lesser*, and the second with the *larger*. Under the name of *grains of paradise—grana paradisi*—small, brown, angular seeds, of a strong odour, and a pungent, aromatic, peppery taste, are kept in the shops, though not introduced into the catalogues of the Pharmacopœias. They are thought by some to be the seeds of the larger cardamoms separated from the capsule; but are treated as wholly distinct by authors, who refer them to the *Amomum Grana Paradisi* of *Linn.*, growing in Ceylon, Madagascar, and perhaps in Guinea. The following remarks have reference exclusively to the lesser or genuine Malabar cardamoms.

Some confusion has prevailed in relation to the botanical history of the cardamom plant. Linnæus confounded under the name of *Amomum Cardamomum*, two different vegetables—the genuine plant of Malabar, and another growing in Java, and producing larger but much inferior capsules. These were separated by Willdenow, who conferred on the former Sonnerat's title of *Amomum repens*, while he retained the original name for the latter, though not the true cardamom plant. In the tenth vol. of the Linn. Transactions, A.D. 1811, Mr. White, a British Army Surgeon in India, published a very minute description of the Malabar plant, which he had enjoyed frequent opportunities of examining in its native state. From this description, the learned Dr. Maton inferred that the plant, according to Roscoe's arrangement of the Scitamineæ, could not be considered an *Amomum;* and as he was unable to attach it to any other known genus, he proposed to construct a new one, with the name of *Elettaria*, derived from *elettari*, or *ela-tari*, the Malabar name of this vegetable. Sir James Smith afterwards suggested the propriety of naming the new genus *Matonia*, in honour of Dr. Maton; and the latter title having been adopted by Roscoe, has obtained a place in the London and United States Pharmacopœias. This explanation was necessary to account for the discordant nomenclature of the different Colleges. After all, however, it is very doubtful whether the new genus is well founded; and the celebrated Dr. Roxburgh describes the Malabar cardamom plant as an *Alpinia*, with the specific appellation of *A. Cardamomum.* He has been followed by Sprengel, and several other German authorities, and recently by Lindley in England. The only material point in which the plant differs from most of the other Alpiniæ, is that the inflorescence proceeds horizontally from the base of the stem, instead of being terminal. We shall follow the authority of Roxburgh.

ALPINIA. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Scitamineæ.

Gen. Ch. *Corolla* with interior border unilabiate. *Anther* double, naked, (uncrowned). *Capsule* berried, three-celled. *Seeds* a few, or numerous, arilled. *Roxburgh, Asiat. Research.* vol. xi. p. 350.

Alpinia Cardomomum. Roxburgh.—*Elettaria Cardamomum*, Maton.—*Matonia Cardamomum*, Roscoe.—*Amomum Repens*, Sonnerat; Willd. *Sp. Plant.* i. 9.—Figured in *Linn. Trans.* x. 248. The cardamom plant has a tuberous horizontal root, furnished with numerous fibres, and sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate, sheathing leaves. These are from nine inches to two feet long, from one to five inches broad, elliptical-lanceolate, pointed, entire, smooth and dark-green on the upper surface, glossy and pale sea-green beneath, with strong midribs, and short footstalks. The scape or flowerstalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in the form of a panicle. The calyx is monophyllous, tubular, and toothed at the margin; the corolla monophyllous and funnel-shaped, with the inferior border unilabiate, three-lobed, and spurred at the base. The fruit is a three-celled capsule, containing numerous seeds.

This valuable plant is a native of the mountainous regions of Malabar, where it springs up spontaneously in the forests after the removal of the undergrowth. From time immemorial great numbers of the natives have depended for a livelihood upon its cultivation. It begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules when ripe are picked from the fruit stems, dried over a gentle fire, and separated by rubbing with the hands from the footstalks and adhering calyx.

Thus prepared, they are from four to seven lines long, from three to four thick, three-sided with rounded angles, obscurely pointed at both ends, longitudinally wrinkled, and of a yellowish-white colour. The seeds which they contain are small, angular, irregular, rough as if embossed upon their surface, of a brown colour, easily reduced to powder, and thus separable from the capsules, which, though slightly aromatic, are much less so than the seeds, and should be rejected when the medicine is given in substance. The odour of cardamom is fragrant, the taste warm, slightly pungent, and highly aromatic. These properties are extracted by water and alcohol, but more readily by the latter. They depend on a volatile oil which rises with water in distillation. The seeds contain, according to Trommsdorff, 4.6 per cent. of volatile oil, 10.4 of fixed oil, 2.5 of a salt of potassa mixed with a colouring principle, 3.0 of starch, 1.8 of azotized mucilage, 0.4 of yellow colouring matter, and 77.3 of ligneous fibre. The volatile oil is colourless, of an agreeable and very penetrating odour, and of a strong, aromatic, burning, camphorous, and slightly bitter taste. Its sp. gr. is 0.945. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odour and taste. (Trommsdorff, *Annalen der Pharmacie, July*, 1834.) The seeds should be powdered only when wanted for immediate use, as they retain their aromatic properties best while enclosed within the capsules.

Medical Properties and Uses. Cardamom is a warm and grateful aromatic, less heating and stimulating than some others belonging to the class, and very useful as an adjuvant or corrective of cordial, tonic, and purgative medicines. Throughout the East Indies it is largely consumed as a condiment, and is considered almost among the necessaries of life. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

Daucus. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Corolla* somewhat rayed. *Florets* of the disk abortive. *Fruit* hispid with hairs. *Willd.*

Daucus Carota. Willd. *Sp. Plant.* i. 1389; Woodv. *Med. Bot.* p. 130. t. 50. The wild carrot has a biennial spindleshaped root, and an annual, round, furrowed, hairy stem, which divides into long, erect, flower-bearing branches, and rises two or three feet in height. The leaves are hairy, and stand on footstalks nerved on their under side. The lower are large and tripinnate; the upper, smaller and less compound; in both, the leaflets are divided into narrow pointed segments. The flowers are small, white, and disposed in many-rayed compound umbels, which are at first flat on the top and spreading, but when the seeds are formed, contract so as to present a concave cup-like surface. A sterile flower of a deep purple colour is often observable in the centre of the umbel. The general involucrum is composed of several leaves, divided into long narrow segments; the partial is more simple. The petals are five, unequal, and cordate. The fruit consists of two plano-convex hispid seeds, connected by their flat surface.

The Daucus Carota is exceedingly common in this country, growing along the fences, and in neglected fields, which in the months of June and July are sometimes white over their whole surface with its flowers. It grows wild also in Europe, from which it is supposed by some botanists to have been introduced into the United States. The well-known garden carrot is the same plant somewhat altered by cultivation. The officinal portions are the seeds of the wild, and the root of the cultivated variety.

1. Carrot Seeds. These are very light, of a brownish colour, of an oval shape, flat on one side, convex on the other, and on their convex surface presenting four longitudinal ridges, to which stiff whitish hairs or bristles are attached. They have an aromatic odour, and a warm, pungent, and bitterish taste. By distillation they yield a pale yellow volatile oil, upon which their virtues chiefly depend. Boiling water extracts their active properties.

Medical Properties and Uses. Carrot seeds are moderately excitant and diuretic, and are considerably employed, both in domestic practice and by physicians, in chronic nephritic affections, and in dropsy. As they possess to a certain extent the cordial properties of the aromatics, they are especially adapted to cases in which the stomach is enfeebled. They are said to afford relief in the strangury from blisters. From thirty grains to a drachm of the bruised seeds may be given at a dose; or a pint of the infusion, containing the virtues of half an ounce or an ounce of the seeds, may be taken during the day. The whole umbel is often used instead of the seeds alone.

2. Carrot Root. The root of the wild carrot is whitish, hard, coriaceous, branched, of a strong smell, and an acrid disagreeable taste; that of the cultivated variety is reddish, fleshy, thick, conical, rarely branched, of a pleasant odour, and a peculiar sweet, mucilaginous taste. The constituents of the roots are crystallizable and uncrystallizable sugar, a little starch, extractive, gluten, albumen, volatile oil, vegetable jelly (*pectin* of Braconnot), malic acid, saline matters, lignin, and a peculiar crystallizable colouring principle, without odour or taste, called *carotin.* In relation to the nature of *vegetable jelly* much uncertainty has existed. By some it has been considered a modification of gum or mucilage combined with vegetable acid. Braconnot at one time considered it closely analogous to, if not identical with, his pectic acid; but more recent investigations have led him to the conclusion that it is a peculiar principle, out of which the pectic acid is formed by the reaction of an alkali. He proposes to call it *pectin*, a name derived from the Greek word πηκτις and expressive of the peculiar property of gelatinizing, by which it is distinguished. It exists more or less in all vegetables, and is abundant in certain fruits and roots from which jellies are prepared. It may be separated from the juice of fruits by the addition of alcohol, which precipitates it in the form of a jelly. This being washed with weak alcohol and dried, yields a semitransparent substance bearing some resemblance to fish-glue or isinglass. Immersed in 100 parts of cold water, it swells like bassorin, and is ultimately dissolved, forming a homogeneous jelly. With a larger proportion of water it exhibits a mucilaginous consistence. It is less acted on by boiling than by cold water. When perfectly pure it is tasteless and has no effect on vegetable blues. A striking peculiarity is, that by the agency of a fixed alkali or alkaline earthy base it is instantly converted into pectic acid, which unites with the base to form a pectate. This may be decomposed by the addition of an acid, which unites with the alkali and separates the pectic acid. (Braconnot, *Annales de Chimie, Juilet* 1831.) The *pectic acid* thus obtained is in the form of a colourless jelly, slightly acidulous, with the property of reddening litmus paper, scarcely soluble in cold water, more soluble in boiling water, and forming with the latter a solution, which, though it does not become solid on cooling, is coagulated by the addition of alcohol, lime-water, acids or salts, and even of sugar if allowed to stand for some time. With the alkalies the acid forms salts which are also capable of assuming the consistence of a jelly. With the earths and metallic oxides it forms insoluble salts. Braconnot thinks that the pectic acid exists in many plants already formed, being produced by the reaction of alkalies present in the plant upon the pectin.

Medical Properties and Uses. The wild root possesses the same properties with the seeds, and may be used for the same purposes. That of the garden plant has acquired much reputation as an external application to phagedenic, sloughing, and cancerous ulcers, the fetor of which it is supposed to correct, while it sometimes changes the character of the diseased action. It is brought to the proper consistence by scraping. In this state it retains a portion of the active principles of the plant, which render it somewhat stimulant. Boiled and mashed, as usually recommended, the root is perfectly mild, and fit only to form emollient cataplasms.

Carthamus. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ Cinarocephalæ.

Gen. Ch. Receptacle paleaceous, setose. *Calyx* ovate, imbricated, with scales ovate, leafy at the end. *Seed-down* paleaceous, hairy, or none. *Willd.*

Carthamus tinctorius. Willd. *Sp. Plant.* iii. 1706. The *dyers' saffron* or *safflower* is an annual plant, with a smooth erect stem, somewhat branched at top, and a foot or two in height. The leaves are alternate, sessile, ovate, acute, entire, and furnished with spiny teeth. The flowers are compound, in large, terminal, solitary heads. The florets are of an orange-red colour with a funnelshaped corolla, of which the tube is long, slender, and cylindrical, and the border divided into five equal, lanceolate, narrow segments.

The plant is a native of the Levant and Egypt, but is cultivated in various parts of Europe and America. The florets are the part employed. They are brought to us chiefly from the ports of the Mediterranean. Considerable quantities are produced in this country, and sold under the name of American saffron.

Safflower in mass is of a red colour, diversified by the yellowness of the filaments contained within the floret. It has a peculiar slightly aromatic odour, and a scarcely perceptible bitterness. Among its ingredients are two colouring substances—one red, insoluble in water, slightly soluble in alcohol, very soluble in alkaline liquids, and called *carthamite,* (*carthamic acid* by Döbereiner:) the other yellow and soluble in water. It is the former which renders safflower useful as a dye-stuff. Carthamite mixed with finely powdered talc forms the cosmetic powder known by the name of *rouge.*

These flowers are sometimes fraudulently mixed with saffron, which they resemble in colour, but from which they may be readily distinguished by their tubular form, and by the yellowish style and filaments which they enclose.

Medical Properties. In large doses carthamus is said to be laxative; and administered in the state of warm infusion it proves somewhat diaphoretic. It is used in domestic practice, as a substitute for saffron, in measles, scarlatina, and other exanthematous diseases, in order to promote the eruption. An infusion made in the proportion of two drachms to a pint of boiling water is usually employed, and given without restriction as to quantity.

Carum. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Fruit* ovate-oblong, striated. *Involucre* one-leafed. *Petals* keeled, inflexed-emarginate. *Willd.*

Carum Carui. Willd. *Sp. Plant.* i. 1470; Woodv. *Med. Bot.* p. 102. t. 41. This plant is biennial and umbelliferous, with a spindleshaped, fleshy, whitish root, and an erect stem, about two feet in height, branching above, and furnished with doubly pinnate, deeply incised leaves, the segments of which are linear and pointed. The flowers are small and white, and terminate the branches of the stem in erect umbels, which are accompanied with an involucre consisting sometimes of three or four leaflets, sometimes of one only, and are destitute of partial involucre. Each flower is succeeded by two seeds.

The caraway plant is a native of Europe, growing wild in meadows and pastures, and cultivated in many places. It has been introduced into this country. The flowers appear in May and June, and the seeds, which are not perfected till the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food by the inhabitants of the North of Europe. The seeds are the part used in medicine. They are collected by cutting down the plant and threshing it on a cloth. Our markets are supplied partly from Europe, partly from our own gardens. The American seeds are usually rather smaller than those brought from Germany.

Caraway seeds are about two lines in length, slightly curved, with five longitudinal ridges which are of a light yellowish colour, while the intervening spaces are dark brown. They have a pleasant aromatic smell, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. The residue is insipid. They yield their virtues readily to alcohol, and more slowly to water.

Medical Properties and Uses. Caraway is a pleasant stomachic and carminative, occasionally used in flatulent colic, and as an adjuvant or corrective of other medicines. The dose in substance is from a scruple to a drachm. An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is most employed. (See *Oleum Cari.*) The seeds are sometimes baked in cakes, to which they communicate an agreeable flavour, while they serve to stimulate the digestive organs.

CARYOPHYLLUS. *U.S.*

Cloves.

"Eugenia caryophyllata. Gemmæ florales. *The flower buds.*" *U. S.*

Off. Syn. CARYOPHYLLI. Eugenia caryophyllata. Flores nondum explicati, exsiccati. *Lond.;* EUGENIÆ CARYOPHYLLATÆ FLO-

RES. Flores nondum expliciti. *Ed.;* CARYOPHYLLUS. EUGENIA CARYOPHYLLATA. Flores nondum expliciti. *Dub.*

Girofle, Clous de Girofles, *Fr.;* Gewürznelken, *Germ.;* Garofani, *Ital.;* Clavos de espicia, *Span.;* Cravo da India, *Portuguese;* Kruidnagel, *Dutch;* Kerunful, *Arab.*

The genus to which the clove-tree belongs, was denominated *Caryophyllus* by Linnæus. Botanists afterwards ascribed the plant to the genus *Eugenia*, with the specific title *caryophyllata;* and this reference is supported by the authority of all the British Pharmacopœias, as well as that of the United States. It appears, however, that there are slight differences between the characters of the clove-tree and those of the other *Eugeniæ*, which have induced some botanists to arrange the former in a distinct genus. In Persoon's Synopsis, Loudon's Encyclopædia of plants, and various French works, it is described under the title of *Caryophyllus aromaticus;* and according to this arrangement, is the only species of its genus. The characters of the Caryophyllus, as given in Loudon's Encyclopædia, are—" *Calyx* funnel-shaped; *fruit* dry, one or two-celled; otherwise like Eugenia."

EUGENIA. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. *Calyx* four-parted, superior. *Petals* four. *Berry* one-celled, one-seeded. *Willd.*

Eugenia caryophyllata. Willd. *Sp. Plant.* ii. 965; Woodv. *Med. Bot.* p. 538. f. 193. This small tree is one of the most elegant of those which inhabit the sunny clime of India. It has a pyramidal form, is always green, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth grayish bark. The leaves are about four inches in length by two in breadth, ovate lanceolate, pointed at both ends, entire, sinuated, with many parallel veins on each side of the midrib, supported upon long footstalks, and opposite to each other upon the branches. They have a firm consistence, a shining green colour, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odour.

The natural geographical range of the clove-tree is extremely limited. It was formerly confined to the Molucca islands, in most of which it grew abundantly before their conquest by the Dutch. By the monopolizing policy of this commercial people, the trees were extirpated in nearly all the islands except Amboyna and Ternate, which were under their immediate inspection. Notwithstanding, however, the jealous vigilance of the Dutch, a French governor of the Isle of France and of Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the Moluccas, and introducing them into the colonies under his control. Five years afterwards, the clove-tree was introduced into Cayenne and the West Indies, and in 1803 into the Island of Sumatra. It is now cultivated largely in these and other places; and commerce has ceased to depend on the Moluccas for supplies of this valuable spice.

The unexpanded flower buds are the part of the plant employed, under the ordinary name of cloves.* They are first gathered when the tree is about six years old. It is said that the full-blown flower and the fruit are destitute of aromatic properties. The buds are picked by the hand, or separated from the tree by long reeds, and are then quickly dried. In the Moluccas they are said to be sometimes immersed in boiling water, and afterwards exposed to smoke and artificial heat, before being spread out in the sun. In Cayenne and the West Indies they are dried simply by the solar heat.

---

* The peduncles of the flowers have been sometimes employed. They possess the odour and taste of the cloves, though in a less degree, and furnish a considerable quantity of essential oil. The French call them *griffes de girofles.*

Cloves appear to have been unknown to the ancients. They were first introduced into Europe by the Arabians, and were circulated through the medium of Venetian commerce. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese; but was subsequently wrested from them by the Dutch, by whom it was long monopolized. Within a few years, however, the extended culture of the plant has opened new sources of supply; and the commerce in cloves is no longer restricted to a single nation. The United States derive their chief supplies from the West Indies and the European colonies in Guiana. Of the average annual import, according to the custom house returns, from 1820 to 1828 inclusive, 43,240 pounds were brought from the West Indies or South America, and 12,828 from France; while from England, Holland, and the East Indies together, the amount imported was only 11,090 pounds; and as the cloves obtained from France were probably of American growth, it appears that we can receive but a very small proportion of those produced in the Moluccas. The latter are said to be thicker, darker, heavier, more oily, and more highly aromatic than those of the colonies to which the clove-tree has been transplanted.

Properties. Cloves resemble a nail in shape, are usually rather more than half an inch long, and have a round head with four spreading points beneath it. Their colour is externally deep brown, internally reddish; their odour strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves are large, heavy, brittle, and exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and smell, they are inferior. We are told that those from which the essential oil has been distilled are sometimes fraudulently mixed with the genuine.

Trommsdorff obtained from 1000 parts of cloves 180 of volatile oil, 170 of astringent extractive matter, 130 of gum, 60 of resin, 280 of vegetable fibre, and 180 of water. M. Lodibert afterwards discovered a fixed oil, aromatic and of a green colour, and a white resinous substance which crystallizes in fasciculi composed of very fine diverging silky needles, without taste or smell, soluble in ether and boiling alcohol, and exhibiting no alkaline reaction. This substance, called by M. Bonastre *caryophyllin*, was found in the cloves of the Moluccas, of Bourbon, and of Barbadoes, but not in those of Cayenne. Berzelius considers it a stearoptene, and probably identical with that deposited by the oil of cloves when long kept. M. Dumas has discovered another crystalline principle, which forms in the water distilled from cloves, and is gradually deposited. Like caryophyllin, it is soluble in alcohol and ether, but differs from that substance in assuming a red colour when touched with nitric acid. M. Bonastre proposes for it the name of *eugenin*. (*Jour. de Pharm.* xx. 565.) Water extracts the odour of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol, and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid when deprived of the oil by distillation with water, while the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. For an account of the oil of cloves, see *Oleum Caryophylli.*

Medical Properties and Uses. Cloves are among the most stimulant of the aromatics, but like others of this class exert less effect upon the system at large than on the part to which they are immediately applied. They are sometimes administered in substance or infusion to relieve nausea and vomiting, correct flatulence, and excite languid digestion; but their chief use is to assist or modify the action of other medicines. They enter as ingredients into several officinal preparations. Their dose in substance is from five to ten grains.

The French Codex directs a *tincture of cloves* to be prepared by digesting for six days, and afterwards filtering, a mixture of 2 parts by weight of powdered cloves and 8 of alcohol of 32° Baumé. Three ounces to the pint of rectified alcohol is a sufficiently near approximation.

CASCARILLA. *U.S.*

Cascarilla.

"Croton Eleutheria. Cortex. *The bark.*" *U.S.*

Off. Syn. CASCARILLÆ CORTEX. Croton Cascarilla. Cortex. *Lond.;* CROTONIS ELEUTHERIÆ CORTEX. *Ed.;* CASCARILLA. CROTON CASCARILLA. Cortex. *Dub.*

Cascarille, *Fr.;* Cascarillrinde, *Germ.;* Cascariglia, *Ital.;* Chacarila, *Span.*

Croton. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. Male. *Calyx* cylindrical, five-toothed. *Corolla* five-petalled. *Stamens* ten to fifteen. Female. *Calyx* many-leaved. *Corolla* none. *Styles* three, bifid. *Capsule* three-celled. *Seed* one. *Willd.*

Cascarilla has been ascribed by different authors to different species of Croton. The London and Dublin Pharmacopœias indicate the *C. Cascarilla;* those of the United States and of Edinburgh, the *C. Eleutheria.* Both species grow in the West Indies, and it is not impossible that the bark of both may have been sold as cascarilla; but there is reason to believe that the C. Eleutheria is at least the most abundant source of it.

Croton Eleutheria. Willd. *Sp. Plant.* iv. 545; Sloane's Jamaica, vol. ii. t. 174. This species of Croton is a small tree or shrub, said by Browne to be four or five feet in height, but as seen by Dr. Wright in Jamaica, rising to twenty feet, and branching thickly towards the summit. The leaves are entire, ovate or cordate lanceolate, and elongated towards the apex, which is blunt. They are of a bright green colour upon their upper surface, and stand alternately upon short footstalks. The flowers, which are of a whitish colour, are disposed in axillary and terminal racemes. This shrub grows wild in the West Indies, especially the Bahama islands, in one of which—the small island of Eleutheria—it is found so abundantly as to have received its name from that circumstance. It is called by Browne *sea-side balsam.*

Croton Cascarilla. Willd. *Sp. Plant.* iv. 531; Woodv. *Med. Bot.* p. 629. t. 222. This is still smaller than the preceding species, and is called by Browne the *small sea-side balsam.* The stem is branched and covered with a brown bark, of which the external coat is rough and whitish. The leaves are long, very narrow, somewhat pointed, entire, of a bright green colour on the upper surface, downy and of a silvery whiteness on the under.

They are placed alternately on short foot-stalks. The flowers are small, greenish, and disposed in long terminal spikes. This plant is a native of the Bahamas, has been found abundantly in Hayti, and is said also to grow in Peru and Paraguay. Browne describes it as hot and pungent to the taste. The *Croton lineare* of Jacquin, considered by Willdenow as a variety of the C. Cascarilla, is made a distinct species by Sprengel. It is the wild rosemary of Jamaica, and is said by Dr. Wright to have none of the sensible qualities of cascarilla. Dr. A. T. Thomson may allude to this plant when he states, that the London College erroneously refers the bark to the *Cascarilla* of Linnæus. It is highly probable that the proper *C. Cascarilla* contributes to furnish the medicine.

Cascarilla is brought to this market from the West Indies, and chiefly, as we have been informed, from the island of Eleutheria.* It comes in bags or casks. We have observed it in the shops in two forms so distinct as almost to deserve the title of varieties. In one, the bark is in rolled pieces of every size from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many portions is partially, sometimes wholly removed, leaving a dark-brown surface, while the inner surface has a chocolate colour, and the fracture is reddish-brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety, which is now most common in the Philadelphia market, consists entirely of very small pieces not more than an inch or two in length, very thin, without the white epidermis, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fibre attached to their inner surface, and presenting an appearance precisely as if shaved by a knife from the stem or branches of the shrub. Whether these two varieties are derived from distinct species, or differ only from the mode of collection, or the part of the plant from which they are taken, it is difficult to determine. May not one be the product of the C. Cascarilla, the other of the C. Eleutheria?

Properties. Cascarilla has an aromatic odour, rendered much more distinct by friction, and a warm, spicy, bitter taste. It is brittle, breaking with a short fracture. When burnt it emits a pleasant odour very closely resembling that of musk, but weaker and more agreeable. This property serves to distinguish it from all other barks. Trommsdorff found it to contain 1.6 of a greenish-yellow volatile oil, having a penetrating odour analogous to that of the bark, and the sp. gr. 0.938, 15.1 of a brown, soft, slightly bitter resin, 18.7 of bitter extractive mixed with gum and traces of muriate of potassa, and 65.6 of lignin. (Berzelius, *Traité de Chim.*) Either alcohol or water will partially extract its active matters; but diluted alcohol is the proper menstruum.

Medical Properties and Uses. This bark is aromatic and tonic. It was known in Germany so early as the year 1690, and was much used as a substitute for Peruvian bark by those who were prejudiced against this febrifuge, in the treatment of remittent and intermittent fevers. It has, however, lost much of its reputation; and is now employed only where a pleasant and gently stimulant tonic is desirable; as in dyspepsia, chronic diarrhœa and dysentery, flatulent colic, and other cases of debility of the stomach or bowels. It is sometimes advantageously combined with the more powerful bitters. It may be given in powder or infusion. The dose of the former is from a scruple to half a drachm, which may be repeated several times a day. In consequence of its pleasant odour when burnt, some smokers mix it in small quantity with their tobacco; but it is said when thus employed to occasion vertigo and intoxication.

---

* In a note by Mr. Don, published in the Edinburgh New Philosophical Journal for April 1834, the author observes; "I rather incline to the opinion of Boulduc, Spielman, and others, that the cascarilla bark is a production of the Spanish Main, for it does not appear that it ever was obtained from Jamaica, or even from the Bahama Islands." Upon inquiry from merchants engaged in the trade of drugs in Philadelphia, we have learned, that cascarilla is brought from the Bahama Islands, and that little or none comes from other places.

CASSIA FISTULA. *U.S.*

Purging Cassia.

"Cassia fistula. *Willd.* Cathartocarpus fistula. *Persoon.* Fructus. *The fruit.*" *U.S.*

Off. Syn. CASSIÆ PULPA. Cassia Fistula. Lomentorum pulpa. *Lond.;* CASSIÆ FISTULÆ FRUCTUS. *Ed.;* CASSIA FISTULA. Pulpa leguminis. *Dub.*

Casse, *Fr.;* Röhrenkassie, *Germ.;* Polpa di Cassia, *Ital.;* Cana Fistula, *Span.*

Cassia. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Leguminosæ.

Gen. Ch. *Calyx* five-leaved. *Petals* five. *Anthers* three upper, sterile; three lower, beaked, *Lomentum. Willd.*

The tree which yields the purging cassia is ranked by many botanists in a distinct genus, separated from the Cassia and denominated *Cathartocarpus*, of which the following is given as the essential generic character. "*Calyx* five-parted, deciduous. *Corolla* regular, of five petals. The lower *filaments* bowed. *Pod* long, woody, many-celled. *Cells* filled with pulp." *Lindley*, in *Loud. Encyc. of Plants.*

Cassia Fistul. Willd. *Sp. Plant.* ii. 518; Woodv. *Med. Bot.* p. 445. t. 160.—*Cathartocarpus Fistula.* Persoon, *Synops.* i. 459. This is a large tree, rising to the height of forty or fifty feet, with a trunk of hard heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth ash-coloured bark. The leaves are commonly composed of five or six pairs of opposite leaflets, which are ovate, pointed, undulated, smooth, of a pale green colour, from three to five inches long, and supported upon short petioles. The flowers are large, of a golden yellow colour, and arranged in long pendent axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous pods, which, when agitated by the wind, strike against each other, and produce a sound that may be heard at a considerable distance.

This species of Cassia is a native of Upper Egypt and India, whence it is generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in Insular and Continental India, Cochin China, Egypt, Nubia, the West Indies, and the warmer parts of America. The fruit is the officinal portion of the plant. It is imported from the East and West Indies, chiefly from the latter, though at present it is very rare in our markets.

Properties. Cassia pods are a foot or more in length, straight or but slightly curved, cylindrical, less than an inch in diameter, with a woody shell, externally of a dark brown colour, and marked with three longitudinal shining bands, extending from one end to the other, two of which are in close proximity, appearing to constitute a single band, and the third is on the opposite side of the pod. These bands mark the place of junction of the valves of the legume, and are represented as sometimes excavated in the form of furrows. There are also circular depressions at unequal distances. Internally the pod is divided into numerous cells by thin transverse plates, which are covered with a soft, black pulp. Each cell contains a single, oval, shining seed. The pods brought from the East Indies are smaller, smoother, have a blacker pulp, and are more highly esteemed than those which come from the West Indies. We have seen a quantity of pods in this market, said to have been brought from Barbary, and sold as cassia pods, which were an inch and a half in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but answered all the purposes required of the medicine. They were probably derived from a different plant.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining, and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place. The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures, and removing the pulp by a spatula.

The pulp is the portion considered officinal by the London and Dublin Colleges; but as it is the pod that is usually kept in the shops, the Edinburgh and United States Pharmacopœias designate the latter. Cassia pulp has a slight rather sickly odour, and a sweet mucilaginous taste. From the analysis of M. Henry it appears to contain sugar, gum, a substance analogous to tannin, a colouring matter soluble in ether, traces of a principle resembling gluten, and a small quantity of water.

Medical Properties and Uses. Cassia pulp is gently laxative, and may be advantageously given in small doses in cases of habitual costiveness. In quantities sufficient to purge, it occasions nausea, flatulence, and griping. In this country it is very rarely prescribed, except as an ingredient in the confection of senna, which is a highly pleasant and useful laxative preparation. The dose of the pulp as a laxative is one or two drachms, as a purge one or two ounces.

Off. Prep. Confectio Cassiæ, *Lond.*, *Ed.*, *Dub.;* Confectio Sennæ, *U.S.*, *Lond.* W.

CASSIA MARILANDICA. *U.S.*

American Senna.

“Cassia Marilandica. Folia. *The leaves.*” *U.S.*

CASSIA. See CASSIA FISTULA.

Cassia Marilandica. Willd. *Sp. Plant.* ii. 524; Bigelow, *Am. Med. Bot.* ii. 116; Barton, *Med. Bot.* i. 137. This is an indigenous perennial plant, of vigorous growth, sending up annually numerous round, erect, nearly smooth stems, which are usually simple, and rise from three to six feet in height. The leaves are alternate, and composed of from eight to ten pairs of oblong lanceolate, smooth, mucronate leaflets, green on their upper surface, pale beneath, and connected by short petioles with the common footstalk, which is compressed, channeled above, and furnished near its base with an ovate, stipitate gland. The flowers, which are of a beautiful golden yellow colour, grow in short axillary racemes at the upper part of the stem. The calyx is composed of five oval, obtuse, unequal, yellow leaves; the corolla of the same number of spatulate, concave petals, of which three are ascending, and two descending and larger than the others. The stamens are ten, with yellow filaments and brown anthers, which open by a terminal pore. The three upper stamens bear short abortive anthers; the three lowermost are long, curved, and tapering into a beak. The germ, which descends with the latter, bears an erect style terminating in a hairy stigma. The fruit is a pendulous legume, from two to four inches long, linear, curved, swelling at the seeds, somewhat hairy, and of a blackish colour.

The *American senna*, or *wild senna* as it is sometimes called, is very common in all parts of the United States south of New York, and grows naturally as far northward as the southern boundary of Massachusetts. It prefers a low moist rich soil, in the vicinity of water, and though frequently found in dryer and more elevated places, grows most abundantly and luxuriantly in the flat ground on the borders of rivers and ponds. It is sometimes cultivated to the northward in gardens for medical use. In the months of July and August, when it is in full bloom, it exhibits a rich and beautiful appearance. The leaves should be collected in August, or the beginning of September, and carefully dried.

They are sometimes brought into the market compressed into oblong cakes, such as those prepared by the Shakers from most herbaceous medicinal plants. The leaflets are from an inch and a half to two inches long, from one quarter to half an inch in breadth, thin, pliable, and of a pale green colour. They have a feeble odour, and a nauseous taste somewhat analogous to that of senna. Water and alcohol extract their virtues. They were analyzed by Mr. Martin, of Philadelphia, and found to contain a principle analogous to *cathartin* in chemical properties and effects on the system, albumen, mucilage, starch, chlorophylle, yellow colouring matter, volatile oil, fatty matter, resin, and lignin, besides salts of potassa and lime. (*Am. Journ. of Pharm.* I. 22.)

Medical Properties and Uses. American senna is an efficient and safe cathartic, closely resembling the imported senna in its action, and capable of being substituted for it in all cases in which the latter is employed. It is, however, less active; and to produce an equal effect must be administered in a dose about one-third larger. It is habitually used by many practitioners in the country. Like senna, it is most conveniently given in the form of infusion, and should be similarly combined in order to obviate its tendency to produce griping. W.

mens ten to twenty. Female. *Calyx* five or six-leaved, muricate. *Corolla* none. *Germs* three. *Stigmas* pencil-formed. *Nuts* three, included in the echinated calyx. *Willd.*

Castanea pumila. Willd. *Sp. Plant.* iv. 461; Michaux, *N. Am. Sylv.* iii. 15. The chinquapin is an indigenous shrub or small tree, which, in the Middle States, rarely much exceeds seven or eight feet in height; but in Carolina, Georgia, and Louisiana, sometimes attains an elevation of thirty or forty feet, with a diameter of trunk equal to twelve or fifteen inches. The leaves are oblong, acute, mucronately serrate, and distinguished from those of the chestnut, which belongs to the same genus, by their whitish and downy under surface. The barren flowers are grouped upon axillary peduncles three or four inches long; the fertile aments are similarly disposed but less conspicuous. The fruit is spherical, covered with sharp prickles, and encloses a brown nut which is sweet and edible, but differs from the chestnut in being much smaller, and convex on both sides.

The tree extends from the banks of the Delaware, southward to the Gulf of Mexico, and south-westward to the Mississippi. It is most abundant in the southern portion of this tract of country. The bark is the part used. It is astringent and tonic, and has been employed in the cure of intermittents; but has no peculiar virtues to recommend it, and might well be spared even from the Secondary Catalogue of the Pharmacopœia. W.

CASTOREUM. *U.S., Lond., Ed., Dub.*

Castor.

"Castor fiber. Concretum sui generis. *A peculiar concrete substance.*" *U.S.*

Castoréum, *Fr.;* Bibergeil, *Germ.;* Castoro, *Ital.;* Castoreo, *Span.*

In the beaver, *Castor fiber* of naturalists, between the anus and external genitals of both sexes, are two pairs of membranous follicles, of which the lower and larger are pear-shaped, and contain an oily, viscid, highly odorous substance, secreted by glands which lie externally to the sac. This substance is called castor. After the death of the animal, the follicles containing it are removed and dried either by smoke or in the sun; and in this state are brought into the market.

This drug is derived either from the northern and north-western parts of the American continent, or from the Russian dominions; and is distinguished according to its source into the Canadian or American and Russian castor. Of the latter but a very small portion reaches this country. That which is brought to Philadelphia is derived chiefly from Missouri.

Castor comes to us in the form of solid unctuous masses, contained in sacs about two inches in length, larger at one end than at the other, much flattened and wrinkled, of a blackish colour externally, and united in pairs by the excretory ducts which connect them in the living animal. In each pair, one sac is generally larger than the other. They are divided internally into numerous cells containing the castor, which, when the sacs are cut or torn open, is exhibited of a brown or reddish-brown colour, intermingled more or less with the whitish membrane forming the cells. Those brought from Russia are larger, fuller, heavier, and less tenacious than the American; and their contents, which are of a rusty or liver-colour, have a stronger taste and smell, and are considered more valuable as a medicine. In the castor from Missouri, the contents of the sac are sometimes almost white, and evidently of inferior quality. It is said by M. Kohli, that the Canadian castor, treated with distilled water and ammonia, affords an orange precipitate, while the matter thrown down by the Russian under similar treatment is white.

Properties. Good castor has a strong, fetid, peculiar odour, a bitter, acrid, and nauseous taste; and a colour more or less tinged with red. It is of a softer or harder consistence according as it is more or less thoroughly dried. When perfectly desiccated, though still somewhat unctuous to the touch, it is hard, brittle, and of a resinous fracture. Its chemical constituents, according to Brandes, whose analysis is the most recent, are volatile oil; a resinous matter; albumen; a substance resembling ozmazome; mucus; urate, carbonate, benzoate, phosphate, and sulphate of lime; acetate and muriate of soda; muriate, sulphate, and benzoate of potassa; carbonate of ammonia; membranous matter; and a peculiar proximate principle previously discovered by M. Bizio, an Italian chemist, and called by him *castorin.* This principle crystallizes in long, diaphanous, fasciculated prisms, has the smell of castor, of which it is alleged to be the active constituent, and a taste like that of copper. It is insoluble in cold water and in cold alcohol; but is dissolved by one hundred parts of the latter liquid at the boiling temperature, and by the essential oils. It possesses neither alkaline nor acid properties. It may be obtained by treating castor minutely divided with six times its weight of boiling alcohol, filtering the liquor while hot, and allowing it to cool. The *castorin* is slowly deposited, and may be purified by the action of cold alcohol. Its claim to be considered the active principle of castor is very doubtful.

Alcohol and sulphuric ether extract the virtues of castor. An infusion made with boiling water has its sensible properties in a slight degree; but the odorous principle of the drug is dissipated by decoction.

The virtues of castor are impaired by age; and the change is more rapid in proportion to the elevation of temperature. Moisture promotes its speedy decomposition. In a dry cool place it may be kept for a long time without material deterioration. When quite black, with little taste or smell, it is unfit for use. A factitious preparation is sometimes sold, consisting of a mixture of various drugs, scented with genuine castor, intermingled with membrane, and stuffed into the scrotum of a goat. The fraud may be detected by the comparatively feeble odour, the absence of other characteristic sensible properties, and the want of the smaller follicles containing fatty matter, which are always attached to the real bags of castor.

Medical Properties and Uses. Castor is moderately stimulant and antispasmodic. The experiments of Thouvenel prove, that in large doses it quickens the pulse, increases the heat of the skin, and produces other symptoms of general excitement; but its force is chiefly directed to the nervous system, and in small doses it scarcely disturbs the circulation. It has also enjoyed a high reputation as an emmenagogue. It was employed by the ancients. Pliny and Dioscorides speak of it as useful in hysteria and amenorrhœa. In Europe, especially on the continent, it is still frequently prescribed in low forms of fever attended with nervous symptoms, in spasmodic diseases, such as hysteria and epilepsy, in many anomalous nervous affections, and in diseases dependent on or connected with suppression or retention of the menses. The practitioners of this country rarely resort to it. The dose in substance is from ten to twenty grains, which may be given in bolus, or emulsion. The tincture is sometimes employed.

Acacia Catechu. Willd. *Sp. Plant.* iv. 1079; Woodv. *Med. Bot.* p. 433. t. 157. According to Mr. Kerr, whose description has been followed by most subsequent writers, the Acacia Catechu is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. The leaves, which stand alternately upon the younger branches, are composed of from fifteen to thirty pairs of pinnæ nearly two inches long, each of which is furnished with about forty pairs of linear leaflets, beset with short hairs. At the base of each pair of pinnæ is a small gland upon the common footstalk. Two short, recurved spines are attached to the stem at the base of each leaf. The flowers are in close spikes, which arise from the axils of the leaves, and are about four or five inches long. The fruit is a lanceolate, compressed, smooth, brown pod, with an undulated thin margin; and contains six or eight roundish flattened seeds, which when chewed emit a nauseous odour.

This species of Acacia is a native of Hindostan, where it grows abundantly in the provinces of Bahar and Canara. Like most others of the same genus it abounds in astringent matter, which may be extracted by decoction. Catechu is an extract from the wood of the tree.

This drug had been long known in medicine before its true source was discovered. It was at first called *terra Japonica*, under the erroneous impression that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the Materia Medica to be an extract obtained from the *betel-nut*, which is the fruit of a species of palm, denominated by Linnæus *Areca Catechu.* The true origin of the drug was made known by Mr. Kerr, assistant-surgeon of the civil hospital in Bengal, who had an opportunity not only of examining the tree from which it was obtained, but also of witnessing the process of its extraction. According to Mr. Kerr, the manufacturer, having carefully cut off the exterior white part of the wood, reduces the interior brown or reddish-coloured portion into chips, which he then boils in water in unglazed earthen vessels, till all the soluble matter is dissolved. The decoction thus obtained is evaporated first by artificial heat, and afterwards in the sun, till it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. It is probable that some difference exists in the mode of its preparation. According to some authors, the unripe fruit and leaves are also submitted to decoction, and Mr. Kerr states that the areca nut may sometimes be added to the other ingredients in places where it is abundant. It is probable that what is sold as catechu in the East is derived from various sources. Dr. Duncan in his Dispensatory remarks, that many varieties have been sent to him from different parts of India, and M. Guibourt enumerates nine different kinds which have come into his possession (*Journ. de Pharm. Decemb.* 1831.) The name in the native language signifies the juice of a tree. We are informed by Dr. Ainslie, that, in the bazaars of Lower India, two astringent extracts are sold, resembling catechu in their properties, and employed for the same purposes both by the European and native practitioners. They are derived from the betel-nut, (fruit of the *Areca Catechu*,) and are much used by the natives for chewing, mixed with the leaves of the *Piper Betel*, commonly called betel leaves. They are, however, never exported in any considerable quantity.

Two commercial varieties of *catechu* are spoken of by authors; the *Bengal catechu*, procured chiefly in the province of Bahar, and shipped at Calcutta; and the *Bombay catechu*, prepared in Canara, and named from its place of export. We derive the drug directly from Calcutta, or by orders from London; and it is sold in our markets without reference to its origin. Dr. Duncan states, that the Bombay catechu is of a uniform texture and of a red-brown tint, while that from Bengal is more friable, less consistent, of a chocolate colour externally, with a mixture of chocolate and red-brown internally.

Properties. Catechu, as it comes to us, is in masses of different shapes, some roundish, some flattened, others cubical or oblong, or quite irregular, and of every grade in size, from small angular pieces, which are evidently fragments of the original cakes, to lumps which weigh nearly a pound. The colour is externally of a rusty brown, more or less dark, internally varying from a pale reddish or yellowish-brown to a dark liver colour. The extract has been distinguished into the pale and dark varieties; but there does not appear to be sufficient ground for retaining this distinction. Catechu is inodorous, with an astringent and bitter taste, which is followed by a sense of sweetness. It is brittle, and breaks with a fracture, which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark colour, easily broken into small angular fragments, with a smooth glossy surface, bearing some resemblance to kino. Dr. A. T. Thomson observes, that the dark variety is heavier and has a more austere and bitter taste than the light. Catechu is often mixed with sand, sticks, and other impurities. Its chief chemical constituents are tannin, extractive, and mucilage. Out of 200 parts of Bombay catechu, Sir H. Davy obtained 109 parts of tannin, 68 of extractive, 13 of mucilage, and 10 of insoluble residue. The same quantity of Bengal catechu yielded 97 of tannin, 73 of extractive, 16 of mucilage, and 14 of insoluble residue. The chemical difference between the two commercial varieties is of no practical importance. Catechu is almost entirely soluble in large quantities of water. Dr. Duncan states that 18 ounces at 52° are required to 100 grains of the extract, of which about $\frac{1}{14}$ of earthy matter is left undissolved. The extractive is much less soluble than the astringent principle, which may be almost entirely separated from it by the frequent application of small quantities of cold water. Boiling water dissolves the extractive matter much more readily than cold, and deposites it of a reddish-brown colour upon cooling. The infusion of catechu is of a brown colour, and affords precipitates with concentrated sulphuric and muriatic acids; with the solutions of lime, strontia, and baryta; with the salts of alumina, the nitrate of potassa, sulphate of magnesia, ferrocyanate of potassa, acetate of lead, persulphate of iron, and solutions of albumen and gelatin. The alkalies prevent its precipitation by gelatin, and the carbonates of the alkalies produce only a slight turbidness. *Duncan.*

Medical Properties and Uses. Catechu is gently tonic, and powerfully astringent. The dark coloured has the latter property in a somewhat greater degree than the light, and is therefore usually preferred. The latter, being rather sweeter, is preferred by the Malays, Hindoos, and other Indians, who consume vast quantities of this extract by chewing it, mixed with a small proportion of lime and with aromatics, and wrapped in the leaf of the *Piper Betel.* Catechu may be advantageously used in most cases where astringents are indicated, and, though less employed in this country than kino, is not inferior to it in medicinal virtues. The complaints to which it is best adapted are diarrhœa dependent on debility or relaxation of the intestinal exhalents, and passive hemorrhages, particularly that from the uterus. A small piece of it, held in the mouth and allowed slowly to dissolve, is an excellent remedy in relaxation of the uvula, and the irritation of the fauces and troublesome cough which depend on it. Applied to spongy gums, in the state of powder, it sometimes proves useful; and it has been recommended as a dentrifice in combination with powdered charcoal, Peruvian bark, myrrh, &c. Sprinkled upon the surface of indolent ulcers, it is occasionally beneficial; and is much used in India for the same purpose mixed with other ingredients in the state of an ointment. An infusion or decoction of catechu may be used as an injection in obstinate gonorrhœa, gleet, and leucorrhœa; and we have found it highly beneficial when thrown up the nostrils in arresting epistaxis.

The dose is from ten grains to half a drachm, which should be frequently repeated, and is best given with sugar, gum Arabic, and water.

Gen. Ch. *Receptacle* bristly. *Seed-down* simple. *Corollas of the ray* funnelshaped, longer, irregular. *Willd.*

Centaurea benedicta. Willd. *Sp. Plant.* iii. 2315; Woodv. *Med. Bot.* p. 34. t. 14. The blessed thistle—*carduus benedictus*—is an annual herbaceous plant, the stem of which is about two feet high, branching towards the top, and furnished with long, elliptical, rough leaves, irregularly toothed, barbed with sharp points at their edges, of a bright green colour on their upper surface, and whitish on the under. The lower leaves are deeply sinuated, and stand on footstalks; the upper are sessile, and in some measure decurrent. The flowers are yellow, and surrounded by an involucre of ten leaves, of which the five exterior are largest. The calyx is oval, woolly, and composed of several imbricated scales, terminated by rigid, pinnate, spinous points.

This plant is a native of the South of Europe, and is cultivated in gardens in other parts of the world. It has become naturalized in the United States. The period of flowering is June, when its medicinal virtues are in greatest perfection. The Edinburgh College directs the whole herbaceous part of the plant; the Dublin only the leaves. It should be cut when in flower, quickly dried, and kept in a dry place.

It has a feeble unpleasant odour, and an intensely bitter taste, more disagreeable in the fresh than the dried plant. Water and alcohol extract its virtues. The infusion formed with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The bitterness remains in the extract, which is said to contain nitrate of potassa. *Fée.*

Medical Properties and Uses. The blessed thistle may be so administered as to prove tonic, diaphoretic, or emetic. The cold infusion, made with half an ounce of the leaves to a pint of water, has been employed as a mild tonic in debilitated conditions of the stomach. A stronger infusion, taken warm while the patient is confined to bed, produces copious perspiration. A still stronger infusion, or the decoction, taken in large draughts, provokes vomiting, and has been used to assist the operation of emetics. The herb, however, is at present little employed, as all its beneficial effects may be obtained from chamomile. The dose of the powder as a tonic is from a scruple to a drachm, that of the infusion two fluidounces. W.

CENTAURII CACUMINA. *Lond.*

Flowering Tops of Common European Centaury.

"Chironia Centaurium. *Cacumina.*" *Lond.*

Off. Syn. CHIRONIÆ CENTAURII SUMMITATES. Summitates florentes. *Ed.;* CENTAUREUM. ERYTHRÆA CENTAUREUM. Folia. *Dub.*

Petite centaurée, *Fr.;* Tausengüldenkraut, *Germ.;* Centaurea minore, *Ital.;* Centaura minor, *Span.*

This plant, first ranked among the *Gentianæ*, and afterwards among the *Chironiæ*, is now placed in a new genus separated from the latter by Persoon, and entitled *Erythræa.* As the *Erythræa Centaurium* it is recognised by the Dublin College.

Erythræa. *Sex. Syst.* Pentandria Monogynia.—*Nat.Ord.* Gentianeæ.

Gen. Ch. *Capsule* linear. *Calyx* five-cleft. *Corolla* funnelshaped, with a short limb withering. *Anthers* often bursting, spiral. *Stigmas* two. *Loudon's Encyc.*

Erythræa Centaurium. Loudon's *Encyc. of Plants*, p. 130.—*Chironia Centaurium.* Willd. *Sp. Plant.* i. 1068; Woodv. *Med. Bot.* p. 275. t. 96.

This is a small, annual, herbaceous plant, rising about a foot in height, with a branching stem, which divides above into a dichotomous panicle, and bears opposite, sessile, ovate lanceolate, smooth, and obtusely pointed leaves. The flowers are of a beautiful rose colour, standing without peduncles in the axils of the stems, with their calyx about half as long as the tube of the corolla. The plant grows wild in most of the countries of Europe, adorning the woods and pastures, during the latter part of summer, with its pretty and delicate flowers.

All the green parts of the plant have a strong bitter taste, which they impart to water and alcohol. The flowering summits are generally preferred, though the Dublin College directs the leaves.

Medical Properties and Uses. The common centaury of Europe has tonic properties very closely resembling those of gentian, with which it is associated in the same natural family. It is employed on the other side of the Atlantic in dyspeptic complaints, and formerly had considerable reputation in the treatment of fever. It was one of the ingredients of the Portland powder. In the United States it has been superseded by the *Sabbatia angularis* or American Centaury. The dose of the powder is from thirty grains to a drachm. Another species of Erythræa—the *E. Chilensis*—possesses similar properties, and is employed to a considerable extent in Chili as a mild tonic. W.

CERA ALBA. *U. S., Lond., Ed., Dub.*

White Wax.

Cire blanche, *Fr.;* Weisses Wachs, *Germ.;* Cera bianca, *Ital.;* Cera blanca, *Span.*

CERA FLAVA. *U.S., Lond., Ed., Dub.*

Yellow Wax.

Cire jaune, *Fr.;* Gelbes Wachs, *Germ.;* Cera gialla, *Ital.;* Cera amarilla, *Span.*

Wax is one of the products of the common bee, the *Apis mellifica* of naturalists, which constructs with it the cells of the comb in which the honey and larvæ are deposited. It was at one time a doubtful point, whether the insect elaborated the wax by its own organs, or merely gathered it already formed from vegetables. The question was set at rest by Huber, who fed a swarm of bees exclusively on honey and water, and found nevertheless that they formed a comb consisting of wax. This, therefore, is a proper secretion of the insect. It is produced in the form of scales under the rings of the belly. But wax also exists in plants, bearing in this, as in other respects, a close analogy to the fixed oils, which are found in both kingdoms with almost as little discoverable difference as between animal and vegetable wax. It is, however, the product of the bee only that is recognised as officinal by the Pharmacopœias. This is directed in two forms: 1. that of *yellow wax* procured immediately from the comb; and 2. that of *white wax* prepared by depriving the former of its colour. We shall consider these separately, and shall afterwards give a brief account of *vegetable wax.*

1. Cera Flava or *Yellow Wax.* This is obtained by slicing the comb taken from the hive, draining and afterwards expressing the honey, and melting the residue in boiling water, which is kept hot for some time in order to allow the impurities to separate, and either subside or be dissolved by the water. When the liquid cools the wax concretes, and having been removed and again melted in boiling water, is strained and poured into pans or other suitable vessels. It is usually brought to market in round flat cakes of considerable thickness. The druggists of Philadelphia are supplied chiefly from the Western States and North Carolina, especially the latter, and from Cuba. Some of an inferior quality is imported from Africa.

In this state wax has a yellowish colour, an agreeable somewhat aromatic odour, and a slight peculiar taste. To the touch it is rather soft and unctuous, though of a firm solid consistence and brittle. It has a granular fracture; but when cut with a knife presents a smooth glossy surface, the lustre of which is so peculiar as when met with in other bodies to be called waxy. It does not adhere to the fingers, nor to the teeth when chewed, but is softened and rendered tenacious by a moderate heat. Its point of fusion is 142° F.; its specific gravity from 0.960 to 0.965. Its chemical properties will be detailed under the head of white wax. The colour, odour, and taste of yellow wax depend on some principle associated with it, but not constituting one of its essential ingredients.

Various adulterations have been practised, most of which may be readily detected. Meal, earth, and other insoluble substances, are at the same time discovered and separated by melting and straining the wax. When the fracture is smooth and shining instead of being granular, the presence of resin may be suspected. This is dissolved by cold alcohol, while the wax is left untouched. Tallow and suet are detected by the softness they communicate to the wax, and its unpleasant odour when melted.

Yellow wax is used in medicine chiefly as an ingredient of plasters and cerates.

2. CERA ALBA or *White Wax*. The colour of yellow wax is discharged by exposing it with an extended surface to the combined influence of air, light, and moisture. The process of bleaching it is carried on to a considerable extent in the vicinity of Philadelphia. The wax, previously melted, is made to fall in streams upon a revolving cylinder, kept constantly wet, upon which it concretes, forming thin ribband like layers. These, having been removed, are spread upon linen cloths stretched on frames, and exposed to the air and light; care being taken to water and occasionally turn them. In a few days they are partially bleached; but to deprive the wax completely of colour it is necessary to repeat the whole process once, if not oftener. When sufficiently white it is melted and cast into small circular cakes, which are usually four or five inches in diameter, and about one-third of an inch in mean thickness.

The colour may also be discharged by chlorine; but the wax is said to be somewhat altered.

Perfectly pure wax is white, shining, diaphanous in thin layers, inodorous, insipid, harder and less unctuous to the touch than the yellow, soft and ductile at 95° F., and fusible at about 155°, retaining its fluidity at a lower temperature. According to Saussure, its specific gravity in the solid state is 0.966, at 178° F. 0.834, and at 201° 0.8247. By a great heat it is partly volatilized, partly decomposed; and, when flame is applied to its vapour, takes fire and burns with a clear bright light. It is insoluble in water, and in cold alcohol or ether, but is slightly soluble in boiling alcohol and ether, which deposite it in great measure upon cooling. The essential and fixed oils dissolve it with facility; resin readily unites with it by fusion; and soaps are formed by the action of soda and potassa in solution. It is not affected by the acids at ordinary temperatures, but is converted into a black mass when boiled with concentrated sulphuric acid. Its ultimate constituents are carbon, hydrogen, and oxygen. Dr. John ascertained that it consists of two distinct proximate principles, one of which he called *cerin*, the other *myricin*, the former soluble to a considerable extent in boiling alcohol and ether, and of the sp. gr. 0.969, the latter nearly insoluble in alcohol or ether, whether hot or cold, softer and more fusible than cerin, and of about the same sp. gr. as water. M. Delamatherie succeeded in making wax artificially by the action of diluted nitric acid on olive oil.

White wax has been adulterated with white lead and tallow. The former sinks to the bottom of the vessel when the wax is melted; the latter imparts to it a dull opaque appearance, and a disagreeable odour during fusion. Starch has been employed for the same purpose. It may be detected by dissolving the wax in oil of turpentine, in which the starch is insoluble.

Medical Properties and Uses. Wax has little effect upon the system. Under the impression, however, that it sheathes the inflamed mucous membrane of the bowels, it has been occasionally prescribed in diarrhœa and dysentery, and is mentioned by Dioscorides as a remedy in the latter complaint. By Poerner it is highly recommended in excoriations of the bowels, attended with pain and obstinate diarrhœa. His mode of using it is to melt the wax with oil of sweet almonds or olive oil, and while the mixture is still hot, to incorporate it by means of the yolk of an egg with some mucilaginous fluid. The dose is about half a drachm, to be repeated three or four times a day. Another method is to form an emulsion by means of soap; but it is evident that this would be the most energetic ingredient of the mixture. Wax is sometimes used to fill cavities in carious teeth. Its chief employment, however, is in the formation of ointments, cerates, and plasters. It is an ingredient in almost all the officinal cerates, which, indeed, owe their general title to the wax they contain.

3. VEGETABLE WAX. Many vegetable products contain wax, or a substance closely analogous to it, as one of their constituents. It exists in the pollen of numerous plants; and forms the bloom or glaucous powder which covers certain fruits, and the coating of varnish with which leaves are sometimes supplied. In some plants it exists so abundantly as to be profitably extracted for use. Such is the *Ceroxylon Andicola*, a lofty palm growing on the Mountain of Quindiu in the South American Andes. Upon the trunk of this tree, in the rings left by the fall of the leaves, is a coating of wax-like matter, about one-sixth of an inch thick, which is removed by the natives and employed in the manufacture of tapers. It contains, according to Vauquelin, two-thirds of a resinous substance, and one-third of pure wax. (*Fée.*) But the form of vegetable wax in which the druggists of this country are particularly interested, is that derived from the *Myrica cerifera*, and commonly called *myrtle wax*. (See *Bigelow's Am. Med. Bot.* iii. 32.) This is a diœcious, tetrandrous plant, belonging to the natural order *Myriceæ* of Richard and Lindley. Nuttall gives the following generic character. "MASC. *Ament* oblong. *Calyx* ovate scales. *Corolla* none. FEM. *Flower* as the male. *Styles* two. *Drupe* one-seeded." The species is distinguished, according to Michaux, by its wedge-shaped lanceolate leaves, having a few serratures at top; by its barren lax aments; and its spherical, naked, distinct fruit. The *M. Caroliniensis* of *Willd.*, and *M. Pennsylvanica* of *Lamarck*, are perhaps only varieties of this species. The wax myrtle is an aromatic shrub, growing from one to twelve feet in height, and found in almost all parts of the United States from New England to Louisiana. The fruit, which grows in clusters closely attached to the stems and branches, is small, globular, and covered with a whitish coating of wax, which may be separated for use. Other parts of the plant are said to possess medical virtues. The bark of the root is acrid and astringent, and in large doses emetic, and has been popularly employed as a remedy in jaundice. (See *Bigelow's Med. Bot.* and *Thatcher's Dispens.*) The process for collecting the wax is simple. The berries are boiled in water; and the wax, melting and floating on the surface, is either skimmed off and strained, or allowed to concrete as the liquor cools, and removed in the solid state. To render it pure, it is again melted and strained, and then cast into large

cakes. It is collected in New Jersey, but more abundantly in New England, particularly Rhode Island, whence it is exported to other parts of the country.

Myrtle wax is of a pale grayish-green colour, somewhat diaphanous, more brittle and at the same time more unctuous to the touch than beeswax, of a feeble odour, and a slightly bitterish taste. It is about as heavy as water, and melts at 109° F. It is insoluble in water, scarcely soluble in cold alcohol, soluble, with the exception of about thirteen per cent., in twenty parts of boiling alcohol, which deposites the greater portion upon cooling, soluble also in boiling ether, and slightly so in oil of turpentine. In chemical relations it bears a close resemblance to beeswax, and consists, like that product, of cerin and myricin, containing 87 parts of the former and 13 of the latter in the 100. The green colour depends upon a distinct principle, which may be separated by boiling the wax with ether, and allowing the liquid to cool. The wax is deposited colourless, while the ether remains green. It is probable that the bitter taste also depends upon a principle distinct from the wax itself.

Medical Properties and Uses. This variety of wax has been popularly employed in the United States as a remedy for dysentery; and we are told by Dr. Fahnestock, that he found great advantage from its use in numerous cases during an epidemic prevalence of this complaint. He gave the powdered wax in doses of a teaspoonful frequently repeated, mixed with mucilage or syrup. (*Am. Journ. Med. Scien.* ii. 313.) It is occasionally substituted by apothecaries for beeswax in the formation of plasters, and is used in the preparation of tapers and candles. It is somewhat fragrant when burning, but emits a less brilliant light than common lamp-oil.

W.

CEREVISIÆ FERMENTUM. *Lond., Ed., Dub.*

Yeast.

Levure, *Fr.;* Bierhefen, *Germ.;* Fermento di cervogia, *Ital.;* Espuma de cerveza, *Span.*

This is the frothy substance which rises to the surface of beer while fermenting. A similar substance is always produced during the vinous fermentation of saccharine liquids; but the principles of its formation are unknown.

It is flocculent, frothy, somewhat viscid, semi-fluid, of a dirty yellowish colour, a sour vinous odour, and a bitter taste. At a temperature of 60° or 70°, in a close vessel or damp atmosphere, it soon undergoes putrefaction. Exposed to a moderate heat, it loses its liquid portion, becomes dry, hard, and brittle; and may in this state be preserved for a long time. In France it is brought to the solid state by introducing it into sacs, washing it with water, then submitting it to pressure, and ultimately drying it.

Yeast is insoluble in alcohol or water. It was analyzed by Westrumb, and found to contain in 15142 parts, 13 of potassa, 15 of carbonic acid, 10 of acetic acid, 45 of malic acid, 69 of lime, 240 of alcohol, 120 of extractive, 240 of mucilage, 315 of saccharine matter, 480 of gluten, 13595 of water, besides traces of silica and phosphoric acid. Its bitterness is attributable to a principle derived from the hops. The property for which it is chiefly valued is that of exciting the vinous fermentation in saccharine liquids, and the panary fermentation in various farinaceous substances. This property it owes to the azotized principle or gluten which it contains; for if separated from this constituent, it loses its powers as a ferment, and reacquires them upon the subsequent addition of the gluten. By boiling in water it is deprived of the property of exciting fermentation. At an elevated temperature it is decomposed, affording products similar to those which result from the decomposition of animal matters.

Medical Properties and Uses. Yeast has been highly extolled as a remedy in typhoid fevers, and is said to have been given with advantage in hectic. It is, however, little employed; as its somewhat tonic and stimulant effects, ascribable to the bitter principle of hops, the alcohol, and the carbonic acid which are among its constituents, may be obtained with equal certainty from more convenient medicines. Dr. Hewson, of Philadelphia, informs us, that in a case of typhoid fever attended with great irritability of the stomach, the patient was benefitted and sustained by taking a pint of yeast daily for five days, during which period no other remedy was employed. When largely taken, it generally proves laxative; and it may sometimes be necessary to obviate this effect by opium. Externally applied, it is very useful in foul and sloughing ulcers, the fetor of which it corrects, while it affords a gentle stimulus to the debilitated vessels. It is usually employed mixed with farinaceous substances in the form of a cataplasm.

The dose is from half a fluidounce to two fluidounces every two or three hours.

CETACEUM. *U. S., Lond., Dub.*

Spermaceti.

"Physeter macrocephalus. Concretum sui generis. *A peculiar concrete substance.*" *U. S.*

Off. Syn. SPERMACETI. Ex physetere macrocephalo. *Ed.*

Blanc de baleine, Spermaceti, Cetine, *Fr.;* Wallrath, *Germ.;* Spermaceti, *Ital.,* Esperma de ballena, *Span.*

The spermaceti whale is from sixty to eighty feet in length, with an enormous head, not less in its largest part than thirty feet in circumference, and constituting one-third of the whole length of the body. The upper part of the head is occupied by large cavities, separated from each other by cartilaginous partitions, and containing an oily liquid, which after the death of the animal, concretes into a white unctuous spongy mass, consisting of the proper spermaceti mixed with oil. This mass is removed from the cavities, and the oil allowed to separate by draining. The quantity of crude spermaceti thus obtained from a whale of the ordinary size, is more than sufficient to fill twelve large barrels. It still, however, contains much oily matter and other impurities, from which it is freed by expression, washing with hot water, melting, straining, and lastly by repeated washing with a weak boiling ley of potash. The common whale oil, and that of other cetaceous animals, contain small quantities of spermaceti, which they slowly deposite on long standing. In the last edition of the United States Pharmacopœia, the example of the London College has been followed in substituting, for the former inaccurate title, the more appropriate and less inelegant appellation of *cetaceum.*

Spermaceti is in white, pearly, semitransparent masses, of a crystalline foliaceous texture; friable, soft and somewhat unctuous to the touch; slightly odorous; insipid; of the sp. gr. 0.943; fusible at 112° F. (*Bostock*); volatilizable at a higher temperature without change *in vacuo*, but partially decomposed if the air is admitted; inflammable; insoluble in water; soluble in small proportion in boiling alcohol, ether, and oil of turpentine, but precipitated as the liquids cool; readily soluble in the fixed oils; forming an imperfect soap when heated with the pure alkalies, by which it is converted into the margaric and oleic acids and a peculiar substance named *ethal* by Chevreul; not affected by the mineral acids, except the sulphuric, which decomposes and dissolves it; rendered yellowish and rancid by long exposure to hot air, but capable of being again purified by washing with a warm ley of potash. By Fourcroy, spermaceti was supposed to be identical with adipocire, but Chevreul proved it to be a distinct principle, and proposed for it the name of *cetin*, which has been adopted in France. As found in the shops it is not entirely pure, containing a fixed oil, and often a peculiar colouring principle. From these it is separated by boiling in alcohol, which on cooling deposites the *cetin* in crystalline scales. In this state it does not melt under 120° F., is soluble in 40 parts of alcohol of the sp. gr. 0.821 (*Thenard*), and is harder, more shining, and less unctuous to the touch than ordinary spermaceti. The ultimate constituents of spermaceti are, according to Berard, carbon 81, oxygen 6, hydrogen 13, in 100 parts; according to Saussure, carbon 75.474, hydrogen 12.795, oxygen, 11.377, and nitrogen 0.354.

Medical Properties and Uses. Like the fixed oils, spermaceti has been given as a demulcent in irritations of the pulmonary and intestinal mucous membranes; but it possesses no peculiar virtues; and its internal use has been generally abandoned. It may be reduced to powder by the addition of a little alcohol or almond oil, or suspended in water by means of mucilage or the yolk of eggs and sugar. Externally it is much employed as an ingredient of ointments and cerates.

CHENOPODIUM. *U.S.*

Wormseed.

"Chenopodium anthelminticum. Semina. *The seeds.*" *U.S.*

CHENOPODIUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Chenopodeæ.

Gen. Ch. *Calyx* five-leaved, five-cornered. *Corolla* none. *Seed* one, lenticular, superior. *Willd.*

Chenopodium anthelminticum. Willd. *Sp. Plant.* i. 1304; Barton, *Med. Bot.* ii. 183. This is an indigenous perennial plant, with an herbaceous, erect, branching, furrowed stem, which rises from two to five feet in height. The leaves are alternate or scattered, sessile, oblong lanceolate, attenuated at both ends, sinuated and toothed on the margin, conspicuously veined, of a yellowish-green colour, and dotted on their under surface. The flowers are very numerous, small, of the same colour with the leaves, and arranged in long, leafless, terminal panicles, which are composed of slender, dense, glomerate, alternating spikes.

This species of Chenopodium, known commonly by the name of *wormseed*, and *Jerusalem oak*, grows in almost all parts of the United States, but most vigorously and abundantly in the southern section. It is usually found in the vicinity of rubbish, along fences, in the streets of villages, and in the commons about the larger towns. It flowers from July to September, and ripens its seeds successively through the autumn. The whole herb has a strong, peculiar, offensive, yet somewhat aromatic odour, which it retains when dried. All parts of the plant are occasionally employed; but the seeds only are strictly officinal. These should be collected in October.

As found in the shops, they are small, not larger than the head of a pin, irregularly spherical, very light, of a dull, greenish-yellow or brownish colour, a bitterish, somewhat aromatic, pungent taste, and possessed in a high degree of the peculiar smell of the plant. When deprived, by rubbing them in the hand, of a capsular covering which invests them, they present a shining surface of a very dark colour. They abound in a volatile oil, upon which their sensible properties and medical virtues depend, and which is obtained separate by distillation. (See *Oleum Chenopodii.*) The same oil impregnates to a greater or less extent the whole plant.

The seeds of the *Chenopodium ambrosioides*, which is also an indigenous plant, and very prevalent in the Middle States, are said to be used indiscriminately with those of the *C. anthelminticum*. They may be distinguished by their odour, which is weaker and less offensive, and to some persons agreeable. The plant itself is often confounded with the true wormseed, from which it differs in having its flowers in leafy racemes. This species of Chenopodium has been employed in Europe as a remedy in nervous affections, particularly chorea. Five or six cases of this disease, reported by Plenk, yielded, after having resisted the ordinary means, to the daily use of an infusion of two drachms of the plant in ten ounces of water, taken in the dose of a cupful morning and evening, and associated with the employment of peppermint. (Merat and De Lens, *Dict. de Mat. Med.*)

The *C. Botrys*, which is also known by the vulgar name of *Jerusalem oak*, is another indigenous species, possessing anthelmintic virtues. The plant is said to have been used in France with advantage as a pectoral in catarrh and humoral asthma.

Medical Properties and Uses. Wormseed is one of our most efficient indigenous anthelmintics, and is thought to be particularly adapted to the expulsion of lumbrici in children. A dose of it is usually given before breakfast in the morning, and at bed time in the evening, for three or four days successively, and then followed by calomel or some other brisk cathartic. If the worms are not expelled, the same plan is repeated.

The seeds are most conveniently administered in powder, mixed with syrup in the form of an electuary. The dose for a child two or three years old, is from one to two scruples.

The volatile oil is perhaps more frequently given than the seeds in substance, though its offensive odour and taste sometimes render it of difficult administration. The dose for a child is from five to ten drops, mixed with sugar, or in the form of emulsion.

A tablespoonful of the expressed juice of the leaves, or a wineglassful of a decoction prepared by boiling an ounce of the fresh plant in a pint of milk, with the addition of orange-peel or other aromatic, is sometimes substituted in domestic practice for the ordinary dose of the seeds and oil.

W.

CHIMAPHILA. *U.S.*

Pipsissewa.

"Chimaphila umbellata, *Barton.* Pyrola umbellata, *Bigelow.* Herba. *The herb.*" *U.S.*

Off. Syn. PYROLA UMBELLATA. Herba. *Dub.*

Chimaphila. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Pyroleæ.

Gen. Ch. *Calyx* five-toothed. *Petals* five. *Style* very short, immersed in the germ. *Stigma* annular, orbicular, with a five-lobed disk. *Filaments* stipitate; stipe discoid, ciliate. *Capsules* five-celled, opening from the summits, margins unconnected. *Nuttall.*

This genus was separated from the *Pyrola* by Pursh, and is now admitted by most botanical writers. It embraces two species, the *C. umbellata* and *C. maculata*, which are both indigenous, and known throughout the country by the common title of *winter green.* The generic title was founded upon the vulgar name of the plants. It is formed of two Greek words, χειμα winter, and φιλος a friend. The *C. umbellata* only is officinal.

Chimaphila umbellata. Barton, *Med. Bot.* i. 17.—*Pyrola umbellata.* Willd. *Sp. Plant.* ii. 622; Bigelow, *Am. Med. Bot.* ii. 15. The pipsissewa is a small evergreen plant, with a perennial, creeping, yellowish root, which gives rise to several simple, erect or semi-procumbent stems, from four to eight inches in height, and ligneous at their base. The leaves are wedge-shaped somewhat lanceolate, serrate, coriaceous, smooth, of a shining sap-green colour on the upper surface, paler beneath, and supported upon short footstalks, in irregular whorls, of which there are usually two on the same stem. The flowers are disposed in a small terminal corymb, and stand upon nodding peduncles. The calyx is small, and divided at its border into five teeth or segments. The corolla is composed of five roundish, concave, spreading petals, which are of a white colour tinged with red, and exhale an agreeable odour. The stamens are ten, with filaments shorter than the petals, and with large, nodding, bifurcated, purple anthers. The germ is globular and depressed, supporting a thick and apparently sessile stigma, the style being short and immersed in the germ. The seeds are numerous, linear, chaffy, and enclosed in a roundish, depressed, five-celled, five-valved capsule, having the persistent calyx at the base.

This humble but beautiful evergreen is a native of the northern latitudes of America, Europe, and Asia. It is found in all parts of the United States, and extends even to the Pacific ocean. It grows under the shade of woods, and prefers a loose sandy soil, enriched by decaying leaves. The flowers appear in June and July. All parts of the plant are endowed with active properties. The leaves and stems are kept in the shops.

The *C. maculata*, or *spotted winter green*, probably possesses similar virtues with the *C. umbellata.* The character of the leaves of the two plants will serve to distinguish them. Those of the C. maculata are lanceolate, rounded at the base, where they are broader than near the summit, and of a deep olive green colour, veined with greenish white; those of the officinal species are broadest near the summit, gradually narrowing to the base, and of a uniform shining green. In drying, with exposure to light, the colour fades very much, though it still retains a greenish hue.

Pipsissewa, when fresh and bruised, exhales a peculiar odour. The taste of the leaves is pleasantly bitter, astringent, and sweetish; that of the stems and root unites with these qualities a considerable degree of pungency.

Boiling water extracts the active properties of the plant, which are also imparted to alcohol. The constituents, so far as ascertained, are bitter extractive, tannin, resin, gum, lignin, and saline matters. The active principle has not yet been isolated, though it probably exists in the substance called bitter extractive.

Medical Properties and Uses. This plant is diuretic, tonic, and astringent. It was employed by the aborigines in various complaints, especially scrofula, rheumatism, and nephritic affections. From their hands it passed into those of the European settlers, and was long a popular remedy in certain parts of the country, before it was adopted by the profession. The first regular treatise in relation to it that has come to our knowledge, was the thesis of Dr. Mitchell, published in the year 1803; but little was thought of it till the appearance of the paper of Dr. Sommerville, in the 5th vol. of the London Medico-Chirurgical Transactions. By this writer it was highly recommended as a remedy in dropsy; and his favourable report has been sustained by the subsequent statements of many respectable practitioners. It is particularly useful in cases attended with disordered digestion and general debility, in which its tonic properties and general acceptability to the stomach prove highly useful auxiliaries to its diuretic powers. Nevertheless, it cannot be relied on exclusively in the treatment of the complaint; for though it generally produces an increased flow of urine, it has seldom effected cures. Other disorders, in which it is said to have proved useful, are calculous and nephritic affections, and in general all those complaints of the urinary passages for which uva ursi is prescribed. It is very highly esteemed by some practitioners as a remedy in scrofula, both before and after the occurrence of ulceration; and it has certainly proved highly advantageous in certain obstinate ill-conditioned ulcers and cutaneous eruptions, supposed to be connected with a strumous diathesis. In these cases it is used both internally, and locally as a wash.

The decoction is the preparation usually preferred. It is made by boiling two ounces of the fresh bruised leaves with three pints of water to a quart, and given to the amount of a pint in twenty-four hours. The watery extract may be given in the dose of twenty or thirty grains four times a day.

CIMICIFUGA. *U.S. Secondary.*

Black Snakeroot.

“ Cimicifuga racemosa. *Nuttall.* Cimicifuga serpentaria. *Pursh.* Radix. *The root.*” *U.S.*

Cimicifuga. *Sex. Syst.* Polyandria Di-Pentagynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* four or five-leaved. *Petals* four to eight, deformed, thickish, sometimes wanting. *Capsules* one to five, oblong, many-seeded. *Seeds* squamose. *Nuttall.*

Cimicifuga racemosa. Torrey, *Flor.* 219.—*C. serpentaria.* Pursh, *Flor. Am. Sept.* p. 372.—*Actæa racemosa.* Willd. *Sp. Plant.* ii. 1139.—*Macrotys racemosa.* Eaton's *Manual*, p. 288. This is a tall, stately plant, having a perennial root, and a simple herbaceous stem, which rises from four to eight feet in height. The leaves are large, and ternately decomposed, consisting of oblong ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, wandlike raceme, with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval germ and a sessile stigma. The fruit is an ovate capsule containing numerous flat seeds.

The *black snakeroot*, or *cohosh* as this plant is sometimes called, is a native of the United States, growing in shady and rocky woods, from Canada to Florida, and flowering in June and July. The root is the part employed.

This, as found in the shops, consists of a thick, irregularly bent or contorted body or caudex, from one-third of an inch to an inch in thickness, often several inches in length, furnished with many slender radicles, and rendered exceedingly rough and jagged in appearance by the remains of the stems of successive years, which to the length of an inch or more are frequently attached to the root. The colour is externally dark brown, almost black, internally whitish; the odour is feeble; the taste bitter, herbaceous, and somewhat astringent, leaving a slight sense of acrimony. The root yields its virtues to boiling water. It was found by Mr. Tilghman, of Philadelphia, to contain gum, starch, sugar, resin, wax, fatty matter, tannin and gallic acid, a black colouring matter, a green colouring matter, lignin, and salts of potassa, lime, magnesia and iron. (*Journ. of Phil. Col. of Pharm.* vi. 20.)

Medical Properties and Uses. Cimicifuga unites, with a tonic power, the property of stimulating the secretions, particularly those of the skin, kidneys, and pulmonary mucous membrane. It is thought also by some to have a particular affinity for the uterus. Its common name was probably derived from its supposed power of curing the disease arising from the bite of the rattlesnake. It is employed chiefly in domestic practice as a remedy in rheumatism, dropsy, hysteria, and various affections of the lungs, particularly those resembling consumption. Several cases of chorea are recorded by Dr. Jesse Young, in which it is said to have effected cures; and the editor of the American Journal of the Medical Sciences states, that he was informed by Dr. Physick that he had known it, in the dose of ten grains every two hours, prove successful in the cure of this complaint in several instances. In the cases recorded by Dr. Young, the powdered root was given in the quantity of a teaspoonful three times a day. (*Am. Journ. of Med. Sciences*, ix. 310.) The medicine is usually administered in the form of decoction. An ounce of the bruised root may be boiled for a short time in a pint of water, and one or two fluidounces given for a dose several times a day. W.

The great importance of Peruvian bark, and the extraordinary degree of attention which it has received, as well from naturalists as from physicians and pharmaceutists, entitle it to a fuller consideration, than, in accordance with the plan of this work, can be given to most other articles of the Materia Medica. Our remarks, therefore, on this subject, will be more than usually extensive; and will embrace many particulars in relation to the natural and commercial history of the drug, which, though not absolutely essential to the full understanding of its properties, are possessed of interest for the inquiring mind, and may lead to useful practical results.

Botanical History.

Though the use of Peruvian bark was introduced into Europe so early as 1640, it was not till the year 1737 that the plant which produced it was known to naturalists. In that year, La Condamine, one of the French Academicians who were sent to South America to make observations relative to the figure of the earth, on his journey to Lima, through the province of Loxa, had an opportunity of examining the tree, of which, upon his return, he published a description in the Memoirs of the Academy. Soon afterwards Linnæus gave it the name of *Cinchona officinalis*, in honour of the Countess of Cinchon, who is said to have first taken it to Europe; but, in his description of the plant, he is stated by Humboldt to have united the species discovered by La Condamine with the *C. pubescens*, a specimen of which had been sent him from Santa Fe de Bogota. For a long time botanists were ignorant that more than one species of this genus existed; and the C. officinalis continued, till a comparatively recent date, to be recognised by the Pharmacopœias as the only source of the Peruvian bark of commerce. A plant was at length discovered in Jamaica, having the generic characters of the Cinchona as then established, and received the title of *C. Caribæa.* Analogous species were afterwards met with in various parts of the West Indies; Forster found one in the island of Tongataboo in the South Pacific, Roxburgh another on the Coromandel coast of Hindostan, Nee a third in the Philippines; many new species were discovered in various parts of New-Granada and Peru by Mutis, Zea, Ruiz and Pavon, Humboldt and Bonpland, and Tafalla; several Brazilian plants appeared to certain botanists worthy of ranking in the same genus; and even the southern portion of our own country, and the distant isles of Bourbon and Mauritius, were made to burthen with their productions the already greatly overloaded catalogue. Not less than forty-six different plants have by various authors been brought under the genus Cinchona; and the number would be greatly augmented, were we to admit as distinct species all the varieties for which this rank is claimed by one or another botanist. But in thus throwing together the productions of so many and such distant climates, botanists compelled an association which nature never intended, which many authors indeed have never admitted, and which is now dissolved by universal consent. According to De Candolle, there exists sufficient ground for distributing these various species into at least eight genera; viz. Cinchona, Buena, Remijia, Exostemma, Pinckneya, Hymenodyction, Luculia, and Danais. These genera all belong to the *Class* and *Order* Pentandria Monogynia; *Nat. Ord.* Rubiaceæ, *Juss.*, *tribe* Cinchonaceæ, and *undertribe* Cinchoneæ of *De Candolle.* The *Cinchona* is confined exclusively to New Granada, Peru, and Bolivia. The *Buena* includes two Peruvian and one Brazilian species, the former of which, before their change of name, were designated as the *Cinchona acuminata*, and *C. obtusifolia.* The genus *Remijia* was established by De Candolle, and embraces three shrubs of Brazil, which were ascribed by Aug. de St. Hilaire to the Cinchona, and the bark of which is used as a febrifuge by the natives of the country. To the *Exostemma* belong the West India species, of which there are not less than nine, formerly known as the *Cinchona Caribæa*, *C. floribunda*, &c. To the same genus belong the former *Cinchona Philippica* of the Philippine islands, the *C. corymbifera* of Tongataboo, four species indigenous to Peru, and two discovered by M. de St. Hilaire in Brazil. The *Pinckneya* consists of a single species, inhabiting Georgia and South Carolina, discovered by Michaux the elder, and described in some botanical works by the name of *Cinchona Caroliniana.* The *Hymenodyction* is an East India genus, including the *Cinchona excelsa* of Roxburgh, found on the Coromandel coast. The *Luculia*, of which there is but one species—the *Cinchona gratissima* of Roxburgh's Flora Indica—inhabits the mountains of Nepaul. The *Danais* embraces the *Cinchona Afro-Inda* of Willem.; growing in the Isle of France. Of these various genera, the *Cinchona*, *Buena* or Cosmibuena of Ruiz and Pavon, and the *Exostemma*, have been most generally confounded. The last, however, is decidedly distinguished by the projection of the stamens beyond the corolla, a character expressed in the name of the genus. The two former are still frequently combined by scientific writers. The *Buena* was originally suggested as a distinct genus by Ruiz and Pavon, has been recognised by De Candolle and some other authors, and appears to be sufficiently characterized. Its chief peculiarities are the shape of the corolla, the separation of the calyx from the fruit at maturity, and the opening of the capsule from above downwards. We have briefly noticed these genera, which have at various times been confounded with the true Cinchona, because the barks of some of them have been occasionally substituted in pharmacy for the genuine febrifuge of Peru. We shall now proceed to consider the proper Cinchona.

CINCHONA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Cinchonaceæ.

Gen. Ch. *Calyx* with the tube turbinate, the limb five-cleft, persistent. *Corolla* with the tube terete, and the limb divided into five oblong lobes. *Stamens* five; filaments short and inserted in the middle of the tube; anthers linear, entirely included. *Stigma* bifid, somewhat club-shaped. *Capsule* ovate or oblong, marked with a furrow on each side, two-celled, crowned with the calyx, opening from below upwards. *Seeds* numerous, erect, imbricated upwards, compressed, furnished with a membranous margin.

The plants composing this genus are trees or shrubs. The leaves are opposite, upon short petioles, with flat margins, and are attended with ovate or oblong, foliaceous, free, deciduous stipules. The flowers are terminal, in corymbose panicles, and of a white or purplish rose colour. *De Candolle.*

It has been stated that the genuine cinchona trees are confined exclusively to the continent of South America. Within these limits, however, they are very widely diffused, extending from La Paz, in the former vice-royalty of Buenos Ayres, to the mountainous regions of Santa Martha on the northern coast. Those which yield the bark of commerce grow at various elevations upon the Andes, seldom less than 4000 feet above the level of the sea; and require a temperature considerably lower than that which usually prevails in tropical countries.

There appears to have been much difficulty in arranging the plants belonging to this genus into their appropriate species; and botanists have not only differed among themselves on this point, but have in some instances exhibited a degree of excitement unbecoming the dignity of science. Ruiz and Pavon, in the Flora Peruviana, describe thirteen new species, while Mutis reduced the number to seven, and Professor Zea has attempted to prove, that almost all the efficacious species of Ruiz and Pavon are reducible to the four described by Mutis in the year 1793, in the Literary News of Santa Fe de Bogota. It appears, from the best testimony, that the number of the species has been unnecessarily augmented by certain botanists; mere fugitive differences, depending on peculiarities of situation or growth, having been exaggerated into permanent characteristics. One source of the difficulty of a proper discrimination is stated by Humboldt to be the varying shape of the leaves of the same species, according to the degree of elevation upon the mountainous declivities, to the severity or mildness of the climate, the greater or less humidity of the soil, and to various circumstances in the growth of individual plants. Even the same tree often produces foliage of a diversified character; and a person not aware of this fact, might be led to imagine that he had discovered different species from an examination of the leaves which have grown upon one and the same branch. The fructification partakes, to a certain extent, of the same varying character; and the difficulty is thus still further augmented.

Lambert, in his "Illustration of the genus Cinchona," published in the year 1821, after admitting with Humboldt the identity of several varieties which had received specific names from other botanists, describes nineteen species exclusive of the two Peruvian *Buenæ*. De Candolle enumerates only sixteen well ascertained species.

In the present state of our knowledge, it is impossible to decide from which species of Cinchona the several varieties of bark are respectively derived. The former references of the yellow bark to the *C. cordifolia*, of the pale to the *C. lancifolia*, and of the red to the *C. oblongifolia*, have been very properly abandoned in the last edition of the U. S. Pharmacopœia, though still retained in those of Great Britain. We shall have occasion hereafter to show, that the valuable barks which are now known in the market by these titles, are, at least in two of the three instances, not the product of the species to which they have been ascribed. It is stated by Humboldt, that the property of curing agues belongs to the barks of all the cinchonas with hairy and woolly blossoms, and to those alone. In Lambert's catalogue this division includes seventeen species. We shall notice the most prominent, mentioning also the synonymes employed by different authors.

In relation to two of the species—*C. Condaminea* and *C. lancifolia*—not a little difference of opinion has existed. The name *lancifolia* was applied by Mutis to a tree, first noticed by himself, which flourishes in the neighbourhood of Santa Fe de Bogota, and the bark of which is known at that place by the title of *cascarilla naranjanda*, or orange-coloured bark. From specimens which he received of the Cinchona originally observed by Condamine, from which the celebrated *Cascarilla fina de Uritusinga* was derived, he was induced to consider this tree as identical with the C. lancifolia. But Loxa, in the vicinity of which this fine bark is collected is separated from Bogota, the residence of Mutis, and the locality of his C. lancifolia, by no less than eight degrees of latitude, and was never visited by this botanist; so that he had no opportunity of personally inspecting the plant in its natural state.

While Mutis, five hundred miles to the north of Loxa, was thus identifying the *cascarilla fina* with his own *cascarilla naranjanda*, Ruiz was claiming for his *C. nitida*, which grows at an almost equal distance to the south of that place, the honour of being the plant seen and described by La Condamine. But Ruiz also laboured under the disadvantage of never having visited Loxa, and like Mutis was compelled to form his opinion upon uncertain grounds. Humboldt and Bonpland, who were themselves in that neighbourhood, and had the opportunity of personally inspecting the tree in its native forests, assert that it is neither the *lancifolia* of Mutis nor the *nitida* of Ruiz and Pavon—plants which have since been satisfactorily ascertained to be identical—but a distinct species never before accurately described, which they name, in honour of its first observer, *Condaminea.* Lambert, however, gives his opinion in favour of Mutis, stating that the *scrobiculi* on the leaves, which Bonpland regarded as a permanent differential character, are found more or less numerous in all the species of the genus. Much weight is due to the opinion of this botanist, as he had specimens of both plants before him. Dr. A. T. Thomson in his Dispensatory states, that the C. Condaminea, if not precisely the same with the C. lancifolia, is evidently a variety of that species; and M. Guibourt, in a report presented to the Society of Pharmacy at Paris, coincides with Lambert. If this opinion can be relied on, the C. lancifolia would appear to be very widely spread over the mountainous regions of New Granada and Peru; for Bogota, where it was found by Mutis, is between 4° and 5° of north latitude; while the forests of Huamalies and Xauxa, where the C. nitida of Ruiz and Pavon, now acknowledged to be identical with it, was observed, are from 10° to 12° south of the equator; and the C. Condaminea occupies an intervening station between these two extremes. To this species are also reduced, by the best authors, the *C. glabra* and *C. angustifolia* of the Quinologia of Ruiz, and the *C. lanceolata* of the Flora Peruviana. But giving its due weight to the authority of Mutis, supported by the botanists who have been mentioned, it is impossible not to hesitate, unless with ampler means of forming a correct opinion than we are at present possessed of, in pronouncing Humboldt and Bonpland to have been mistaken; for these celebrated travellers, from their abundant opportunities of personal inspection, from their access to all the knowledge of their predecessors, and from their high scientific qualifications and habits of observation, are indisputably among the first authorities at present existing on the subject of the natural history of the Cinchona. In the remarks, therefore, which follow, the C. Condaminea of Humboldt and Bonpland, and the C. lancifolia of Mutis, will be considered separately, without any decided opinion being pronounced as to the identity of their botanical characters. It is proper, in the present place, to observe, that the causes which tend to perplex botanists in arranging the different species of the genus Cinchona, are particularly applicable to the individual case before us; as, in the language of Humboldt, "the C. Condaminea varies amazingly in its leaves."

1. *C. Condaminea.* Humb. et Bonpl. *Pl. Equin.* i. p. 33. t. 10; De Cand. *Prodrom.* iv. 352. This tree, when full grown, has a stem about eighteen feet high and a foot in thickness, with branches arranged in opposite pairs, of which the lower are horizontal; the higher rise upwards at their extremities. The bark of the trunk is of an ash-gray-colour, with clefts or fissures, and yields on incision a bitter astringent juice; that of the small branches has a greenish hue, is smooth and glossy, and easily separable from the wood. The leaves are oblong, generally when full grown about four inches in length by less than two in breadth, acuminate at both extremities, of a

shining lively green colour, and furnished with glands upon their upper surface, with corresponding scrobiculi or depressions upon the under. In very young plants they are much broader in proportion to their length; and it is an observation of Humboldt, that the older the tree, the narrower is the leaf. The corolla has a rose-coloured tube, and a woolly border, snow white upon its upper surface. The capsules are ovate, and twice as long as they are broad. The tree grows under the fourth degree of south latitude, on the declivities of the mountains, at an elevation of from about one mile to a mile and a half, and in a mean temperature of 67° of Fahrenheit. It is confined to the neighbourhood of Loxa, and produces the variety of bark commonly known by the name of *crown bark of Loxa.*

2. *C. lancifolia.* Mutis, *Period. de Santa Fe*, p. 465; De Cand. *Prodrom.* iv. 352.—*C. nitida*, Ruiz and Pavon, *Fl. Peruv.* ii. 50. t. 191.—*C. lanceolata. Ibid.* iii. 1. t. 223.—*C. angustifolia.* Ruiz, *Quinolog. Suppl.* p. 14. The variety of this species discovered by Mutis in New Granada is a very handsome tree, from thirty to forty-five feet in height, with a trunk from one to four feet in diameter. The leaves are obovate lanceolate, very smooth on both sides, and without glands; the flowers are in large brachiate panicles; the corolla is silky externally; and the capsules are oblong, smooth, and of a length five times greater than their breadth. The tree is quite solitary, never clustering like other Cinchonæ of the same neighbourhood, which are often so crowded together as to form almost closely connected shrubberies. This solitary character appears to pertain to all the more valuable species, and has led to their scarcity in the regions where bark has been long collected. When a tree has been felled, no suckers, as in the inferior species, arise from the roots, and assist to propagate the plant. Perhaps the superiority in size of the full grown C. lancifolia of Mutis over the C. Condaminea as described by Humboldt, is attributable to the fact, that the bark has been gathered in Loxa from the earliest periods of its uses as a medicine, while in New Granada, the commerce in the drug is comparatively of recent date. The C. lancifolia requires a colder climate than the C. Condaminea, growing between the fourth and fifth degrees of north latitude, at an elevation upon the mountains of from 4500 to near 10,000 feet, and in a mean temperature of 61° of Fahrenheit. In the highest situations in which it is found, the thermometer often sinks to 50°, and in the nights is sometimes at the freezing point. Judging from the botanical characters of this species as given by Mutis, it scarcely differs from the C. Condaminea, unless we consider the absence of glands upon the leaves as sufficiently distinctive. That it yields the same kind of bark is to be inferred from the fact, that the *Cascarilla fina de Uritusinga* or Crown bark of Loxa, admitted to be the product of the C. Condaminea, was considered by the experienced Mutis as identical with the *cascarilla naranjanda*, derived from his C. lancifolia; while Ruiz and Pavon, without any communication with Mutis, and at the distance of nearly a thousand miles, claimed a similar identity for the bark of their C. nitida, now generally acknowledged to be the same tree with the C. lancifolia. The Crown bark of Loxa is universally ranked among the pale barks, while that of the C. lancifolia, growing near Bogota, is called *orange coloured;* and this difference of title might appear to indicate a difference in their nature; but the difficulty vanishes when we consider, that the latter name was derived from the colour of the internal surface of the bark, the former from that of the powder; and that the pale barks are orange coloured in their natural state. It is probable that much of the pale bark of commerce, is derived from varieties of the C. lancifolia.

3. *C. cordifolia.* Mutis, *ex Humb. Magaz. Berlin*, 1807, p. 117; Lambert, *Illustration, &c.*, 1821, p. 4. This is a spreading tree, fifteen or twenty feet high, rising on a single erect round stem, which is covered with a smooth bark of a brownish-gray colour. The smaller branches have a lighter coloured bark, and are covered with a fine down. The leaves vary much in form; but some of a heart-shape are to be found on almost every branch, and have given origin to the name of the species. They are usually roundish ovate, about nine inches long, smooth and shining on the upper surface, ribbed and pubescent on the under. The down upon the leaves and smaller branches has given rise to the name of *velvet bark*, by which the tree is known to the common people of New Granada. The flowers are in spreading, brachiate, pubescent panicles. The teeth of the calyx are roundish and somewhat mucronate. The capsules are ovate, oblong, cylindrical, and without ribs.

This species was first described by Mutis, who found it in the mountains about Santa Fe de Bogota; and it is said to flourish also in those of Loxa, Cuenca, and the ancient kingdom of Quito. Like the other medicinal species, it grows in the elevated plains, and on the declivities of the Andes at heights varying from 5800 to 9500 feet.

In the British Pharmacopœias, the C. cordifolia is recognised as the source of the officinal yellow bark. It undoubtedly produces the variety known to the Spaniards as the *quina amarilla* or yellow bark of Santa Fe; but this is by no means the article which circulates in the commerce of this country, England, and France, by the name of *yellow bark* or *Calisaya bark*, and which is so largely consumed in the manufacture of the sulphate of quinia. This will be rendered obvious at once by the statement, that the valuable yellow or Calisaya bark is derived exclusively from the western coast of South America on the Pacific; while the C. cordifolia of Mutis flourishes most about Bogota, of which the commercial outlet is Carthagena on the northern coast of the continent. The truth seems to be that this species yields the yellow Carthagena bark, which is probably identical with the *quina amarilla de Santa Fe* of the Spaniards; and the British Colleges have simply followed Mutis in ascribing the yellow bark to the C. cordifolia, without taking into consideration the total want of similarity, except in the shade of colour, between the medicine known to him by that title, and the valuable variety which they intended to adopt as officinal. The yellow bark described by Thomson in the London Dispensatory as derived from the C. cordifolia, is in all respects identical with the *Calisaya*, and totally different from the yellow Carthagena bark, which is probably the real product of this species. In the United States Pharmacopœia this error of the British Colleges has been corrected.

By some authors the *C. pubescens* of Vahl, and the *C. hirsuta* of the Flora Peruviana, are considered mere synonymes of the *C. cordifolia.*

4. *C. pubescens.* Vahl, *in Act. Havn.* i. p. 19. t. 2; Lambert, *Monog.* t. 2.—*C. ovata.* Ruiz and Pavon, *Flor. Peruv.* ii. p. 52. t. 195. This was described and named by Vahl, who received his specimen from the collection of Jussieu at Paris, whither it was brought by Joseph de Jussieu from the neighbourhood of Loxa. It is admitted to be identical with the *C. ovata* of the Peruvian Flora, even by the authors of that work. Bonpland has pronounced it to be the same with the *C. cordifolia;* but Lambert, though he admits their similarity, decides, from dried specimens in his possession, that they are quite distinct. The C. pubescens differs, according to this botanist, from the C. cordifolia, in having longer petioles, the teeth of the calyx less broad and round, the filaments not more than half the length, and the

capsules obscurely ribbed and tomentose, while those of the C. cordifolia are smooth and ribless. The tree grows about Loxa, also in the warmer regions of the Andes near Pozuzo and Panao, and in the forests of Huanuco to the north-east of Lima. It contributes to furnish the bark of commerce, though we are wholly unable to ascertain the particular variety it affords. Ruiz calls its product *cascarilla palido;* and it is not improbable that a portion of the pale bark of Loxa and Lima is derived from it.

5. *C. hirsuta.* Ruiz and Pavon, *Flor. Peruv.* ii. p. 51. t. 192. Humboldt, upon the authority of Zea, erroneously referred this species to the C. cordifolia; and the error has been copied by De Candolle. The two species have not the least resemblance; and Zea himself has acknowledged his mistake. (*Lambert's Illustration.* A. D. 1821, p. 10.) The C. hirsuta derives its name from the stiff hairs upon its extreme branches, leaves, and flowers. The leaves are oval and acute at the base; the flowers glomerate; the segments of the calyx lanceolate and acuminate; and the capsules ovate. It grows in lofty and cold situations upon the Peruvian Andes near Pillao and Acomayo. It attains the height of about fifteen feet, and is then surrounded by shoots springing upwards from its roots, and forming with the parent tree an oval surface, having the appearance of a dome. Its bark is called *delgada* or slender, is very thin, and may be ranked among the pale varieties of English and American pharmacy, the gray of the French. Though a valuable bark, it is seldom gathered, as its extreme fineness renders its collection much less profitable than that of the larger varieties.

6. *C. scrobiculata*, Humb. and Bonpl. *Plant. Equin.* i. p. 165. t. 47; De Cand. *Prodrom.* iv. 352. This is a large tree, attaining the height of forty feet, with oval oblong leaves, from four to twelve inches in length and from two to six in breadth, acute at each end, smooth, shining on the upper surface, and marked on the under with scrobiculi at the axils of the veins. The tube of the corolla is externally pubescent and the limb woolly. The capsule is ovate oblong, with a breadth equal to one-third of its length. The tree was originally described by Humboldt and Bonpland, who found it growing in great abundance on the mountains near the city of Jaën de Bracomoros, where it forms immense forests. They inform us that the bark of its younger branches so much resembles that of the C. Condaminea, that it is difficult to distinguish the two varieties. It cannot, therefore, as stated by De Candolle, be one of the red barks of commerce; for the product of the C. Condaminea is universally classed among the pale or gray barks. It is called by the natives *cascarilla fina*, and probably contributes to form the packages which come to us under the name of Loxa bark.

7. *C. purpurea.* Ruiz and Pavon, *Flor. Peruv.* ii. p. 52. t. 193; De Cand. *Prodrom.* iv. p. 353. Lambert unites this species with the C. scrobiculata of Humb. and Bonp., retaining the present title; but the species are generally considered distinct. The leaves are broadly oval, somewhat wedge-shaped at the base, subcuspidate at the apex, smooth above, slightly pubescent on the veins beneath, and inclining to a purple colour. The flowers are purplish-white, subcorymbose, and disposed in large brachiate panicles. The corolla is slightly tomentose on the outside, with the limb hirsute internally. The capsules are ovate oblong, about an inch in length, a quarter of an inch in breadth, and marked with longitudinal nerves. The tree grows in the Peruvian Andes, near Chinchao, Pati, &c. Its bark is brown on the outside, light brown within, and is called by the natives *Cascarilla boba de hojà morada*, or simply *Cascarilla morada.* It is probably among those derived from Lima, which is the entrepot of the trade in bark from the interior of Peru about Huanuco, &c.

8. *Cinchona oblongifolia.* Mutis, *Mss. ex Humb. Mag. Berl.* i. p. 118. Lambert, *Illust.* 1821. p. 12. This is one of the largest trees of the genus, rising to a great height on a single, erect, round stem, which is covered with a smooth, brownish, ash-coloured bark. The leaves are oblong or cordate, rough, thickly covered with hairs, and of great size, being frequently one or two feet in length. The flowers are in brachiate corymbose panicles. The corolla is pilose, with linear segments; the anthers three times as long as the filaments. The capsules are ovate. This tree was discovered by Mutis in New Granada, where it is very abundant, especially in the vicinity of Mariquita, in about four degrees of N. latitude. It grows at an elevation of from 4000 to 8500 feet. Botanists generally agree with Humboldt and Bonpland in uniting with this species the *C. magnifolia* of the Flora Peruviana, which grows to the south of the equator, upon the mountains of the Panatahuas, near Cuchero, Chinchao, and Chacahuassi, where it was seen by Ruiz and Pavon, in the year 1780. Lambert, however, describes them as different species, having found the characters of each distinct and constant in the specimens in his possession. He states that the C. oblongifolia is distinguished from the C. magnifolia "by its leaves being rounded at the base, often cordate, covered on both sides with rough pilose tomentum. Sometimes, however, the older leaves become nearly naked above. The corolla is covered on the outside with bristly pilose hairs, while that of *magnifolia* has short pubescence. The laciniæ are also much narrower, the style is enclosed with the stamens in the tube of the corolla. The lobes of the stigma are cylindrical, and the capsules are ovate; those of *magnifolia* are linear and cylindrical." *Illustration,* &c., 1821. p. 12.

The C. oblongifolia is called by the natives *cascarilla de flor de azahar,* from the resemblance of its flowers in odour to those of the orange. Till very recently it has been considered as indisputably the source of the best red bark of commerce, which is ascribed to it by the British Pharmacopœias. A little reflection might have convinced those acquainted with the commerce in bark, that this reference was incorrect; for who ever hears of the officinal red bark as coming from Carthagena? and yet this is the port from which the product of the C. oblongifolia, growing in New Granada, is shipped. The mistake originated in that implicit acquiescence with which the statements of Mutis have been received. The tree does, undoubtedly, as asserted by Mutis, produce a red bark; but it is the red Carthagena bark, a comparatively valueless variety, wholly distinct from the genuine red bark, brought from the Pacific and so highly esteemed as a febrifuge. We shall have occasion to say more on this subject hereafter.

9. *C. macrocarpa.* Vahl *in Act. Havn.* i. p. 20. t. 3; De Cand. *Prodrom.* iv. 354.—*C. ovalifolia. Mutis.* This is a shrub about nine feet in height, with elliptical coriaceous leaves, very smooth on the upper surface, somewhat hirsute pubescent beneath. The flowers are in trichotomous panicles. The corolla is externally pubescent, but hirsute on the inner surface of its segments. The capsules are cylindrical, and twice as long as they are broad. This species inhabits the provinces of Loxa and Cuenca, where it forms considerable forests. It was also found by Mutis in New Granada, and grows as far north as Santa Martha. The variety found in the latter locality has leaves smooth on both sides. The tree derived its name from the extraordinary magnitude of its fruit. Its bark is called by the Spaniards *quina blanca,* or white bark, probably from the colour of the epidermis. May not this species be the source of that commercial variety of cinchona

brought from Maracaybo and Santa Martha, in the neighbourhood of which the tree is said by Humboldt to be found?

The species of Cinchona above enumerated are the most interesting, whether from the attention they have attracted or from the value of their products. Several others probably furnish more or less of the bark of commerce. Among these may be mentioned, 10. *C. micrantha* of the Peruvian Flora, a large and handsome tree found by Tafalla, growing in the elevated regions of San Antonio Playa Grande in the Peruvian Andes, and furnishing a bark called *cascarilla fina* by the natives; 11. *C. glandulifera* of the same work, a shrub with several stems about twelve feet high, flourishing in the country to the north of Huanuco, where it is called *cascarilla negrilla;* 12. *C. ovalifolia* of Humboldt and Bonpland, the *C. Humboldtiana* of Rœm. and Schult., a shrub from six to nine feet high, inhabiting the province of Cuenca, where it forms considerable forests, and is called by the natives *cascarilla peluda* or hairy bark; 13. *C. caduciflora* of Humboldt and Bonpland, a very large tree, more than one hundred feet high, growing near the city of Jaen de Bracomoros, and yielding a bark called *cascarilla bova* by the Peruvians; 14. *C. acutifolia* of the Fl. Peruv., a tree twenty-four feet high, discovered by Tafalla in the Peruvian mountains north of Huanuco, near the Taso, and yielding the *cascarilla hoja aguda;* and 15. *C. dichotoma*, which grows to the height of fifteen feet, was discovered by the same botanist in the same region as the preceding species, and affords the bark called *cascarilla aharquilla* by the natives.

Besides these species, several others might be added, which, though named and described by botanists, are not known to furnish any of the bark of commerce. Such are the *C. macrocalyx*, *C. pelalba* and *C. crassifolia* of Pavon, quoted by De Candolle; and the *C. Pavonii*, *C. Humboldtiana*, *C. rotundifolia*, and *C. stenocarpa* described by Lambert, upon the authority of Pavon, and from specimens in his own possession.*

In all the preceding species except the *C. caduciflora*, the corolla is more or less hairy or woolly: the *C. rosea* is the only other strictly belonging to this genus which has the corolla entirely smooth. It rises usually to the height of fifteen feet, and when in blossom presents a very handsome appearance, as well from the richness of its foliage, as from the beauty of its flowers, with which the natives adorn their churches. It inhabits the forests of the Andes near Pozuzo and San Antonio de Playa Grande. Its bark is called *cascarilla parda*.

Commercial History.

For more than a century after Peruvian bark came into use, it was procured almost exclusively from Loxa and the neighbouring provinces. In a memoir published A. D. 1738, La Condamine speaks of the bark of Rhiobamba, Cuenca, Ayavaca, and Jaën de Bracomoros. Of these places, the first two, together with Loxa, lie within the ancient kingdom of Quito, at its southern extremity; the others are in the same vicinity, within the borders of Peru. The drug was shipped chiefly at the Port of Payta, from which it was carried to Spain, and thence spread over Europe. Beyond the limits above mentioned, the Cinchona was not supposed to exist, till, in the year 1753, a gentleman of Loxa, familiar with the aspect of the tree, discovered it while on a journey from the place of his residence to Santa Fe de Bogota, in numerous situations along his route, wherever, in fact, the elevation of the country was equal to that of Loxa, or about 6,500 feet above the level of the sea. This discovery extended quite through Quito into the kingdom of New Granada, as far as two degrees and a half north of the equator. But no practical advantage was derived from it; and the information lay buried in the archives of the vice-royalty, till subsequent events brought it to light. To Mutis undoubtedly belongs the credit of making known the existence of the Cinchona in New Granada. He first discovered it in the neighbourhood of Bogota, in the year 1772. A botanical expedition was some time afterwards organized by the Spanish government, with the view of exploring this part of their American dominions, and the direction was given to Mutis. The researches of the expedition eventuated in the discovery of several species of the Cinchona in New Granada, and a commerce in the bark soon commenced, which was afterwards increased, and carried on with great vigour through the ports of Carthagena and Santa Martha. The English and North Americans, opening a contraband trade with these ports, were enabled to undersell the Spanish merchant, who received his supplies by the circuitous route of Cape Horn; and the barks of New Granada were soon as abundant as those of Loxa in the markets of Europe.

---

* Much weight has been given, in these remarks upon the different species of Cinchona, to the authority of Lambert, who, independently of his familiarity with the subject, resulting from long attention to it, has had opportunities enjoyed by few other botanists of coming to correct conclusions—having in his possession numerous dried specimens of all the species collected by Ruiz and Pavon and their pupils, besides many others derived from other sources.

To these sources another was added about the same time, A. D. 1776, by the discovery of the Cinchona in the centre of Peru, in the mountainous region about the city of Huanuco, which lies on the eastern declivity of the Andes, to the north-east of Lima, at least six degrees to the south of the province of Loxa. To explore this new locality, another botanical expedition was set on foot, at the head of which were Ruiz and Pavon, the distinguished authors of the Flora Peruviana. These gentlemen spent several years in this region, during which time they discovered numerous species that were afterwards described in their Flora. Several of their species, however, are now considered identical with the C. lancifolia previously described by Mutis. Lima became the entrepot for the barks collected around Huanuco; and hence probably originated the name of Lima bark, so often conferred, in common language, not only upon the varieties received through that city, but also upon the medicine generally.

Soon after the last mentioned discovery, two additional localities of the Cinchona were found, one at the northern extremity of the continent near Santa Martha, the other very far to the south, in the provinces of La Paz and Cochabamba, then within the vice-royalty of Buenos Ayres, now attached to the republic of Bolivia. These latter places became the source of an abundant supply of excellent bark, which received the name of Calisaya, probably from a district of country where it was gathered. It was sent partly to the ports on the Pacific, partly to Buenos Ayres.

The consequence of these discoveries, following each other in such rapid succession, was a vast increase in the supply of bark, which was now shipped from the ports of Guayaquil, Payta, Lima, Arica, Buenos Ayres, Carthagena, and Santa Martha. At the same time the average quality was probably deteriorated; for though many of the new varieties were possessed of excellent properties, yet equal care in superintending the collection and assorting of the article could not be exercised now that the field was so extended, as when it was confined to a small portion of the South of Quito and North of Peru. The varieties which were poured into the market soon became so numerous as to burthen the memory, if not to defy the discrimination of the druggist; and the best pharmaceutists found themselves at a loss to discover any permanent peculiarities, which might serve as the basis of a proper and useful classification. This perplexity has continued more or less to the present time; though the discovery of the new alkaline principles has presented a ground of distinction which was before unknown. The restrictions upon the commerce with South America, by directing the trade into irregular channels, had also a tendency to deteriorate the character of the drug. In the complexity of contrivance to which it was necessary to resort to deceive the vigilance of the government, little attention could be paid to a proper assortment of the several varieties; and not only were the best barks mixed with those of inferior species and less careful preparation, but the products of other trees, bearing no resemblance to the Cinchona, were sometimes added, having been artificially prepared so as to deceive a careless observer. The markets of this country were peculiarly ill furnished. The supplies being derived chiefly, by means of a contraband trade, from Carthagena and other ports of the Spanish Main, or indirectly through the Havana, were necessarily of an inferior character; and the little good bark which reached us was imported by our druggists from London, whither it was sent from Cadiz. A great change, however, in this respect, has taken place since the ports on the Pacific have been opened to our commerce. The best kinds of bark have thus been rendered directly accessible to us; and increased intelligence in the community has co-operated with the facility of supply, to exclude from our markets that kind of trash with which they were formerly glutted. Our ships trading to the Pacific, run along the American coast from Valparaiso in Chili to Guayaquil on the western coast of Colombia, stopping at the intermediate ports of Coquimbo, Copiapo, Arica, Callao, Truxillo, &c., from all which they probably receive supplies of bark in exchange for the mercury, piece-goods, flour, &c., which constitute their outward cargo.

The persons who collect the bark are called in South America *Cascarilleros*. Considerable experience and judgment are requisite to render an individual well qualified for this business. He must not only be able to distinguish the trees which produce good bark from those less esteemed, but must also know the proper season and the age at which a branch should be decorticated, and the marks by which the efficiency or inefficiency of any particular product is indicated. The dry season, from September to November inclusive, is the harvest of the bark gatherers. They separate the bark by making a longitudinal incision with a sharp knife through its whole thickness, and then forcing it off from the branch with the back of the instrument. Other means are resorted to when the trunk or larger limbs are decorticated. They consider the branch to be sufficiently mature, when the inner surface of the bark begins to redden upon exposure to the air within three or four minutes after its removal. The next object is to dry the bark in the sun. In the drying process it rolls itself up, or in technical language becomes quilled, and the degree to which this effect takes place, is proportionate directly to the thinness of the bark, and inversely to the age of the branch from which it was derived. In packing the bark for exportation, due care is seldom taken to assort the varieties according either to the species of Cinchona by which they are furnished, or to their resemblance in appearance and character; and it often happens that several different kinds are introduced into the same case. The packages are, in commercial language, called *seroons.* As found in this market, they are usually covered with a case of thick and stiff ox-hide, which is lined within by a very coarse cloth, apparently woven out of some kind of grass.

Means of distinguishing good bark. To the druggist and apothecary it is highly important to possess the means of deciding upon the relative value of the numerous varieties of bark of every quality brought into market, or at least of discriminating between the energetic and inefficient. The following rules are given by men who pretend to a familiar acquaintance with the subject. They are essentially the same with those which, according to Dr. Devoti, a physician of Lima, are practised in South America in choosing the barks proper to be admitted into commerce.

In forming a judgment, it is necessary to consider whether the bark has been taken from a branch of the proper age, and whether it has been carefully dried. Very young bark has not acquired the virtues which render the medicine valuable; that derived from the trunk or older branches has often been injured by time or by the action of parasitic plants; and, to hasten the drying process in certain mountainous situations where the sun has little power, or to increase the rolling, a certain degree of which renders the drug more saleable to the merchants, it is said not to be an uncommon practice to expose the fresh barks injuriously to artificial heat. Bark more than an inch and a half in diameter must have come from the trunk or great branches, that which is smaller than a goosequill from young and immature branches; and both are deemed of inferior quality. The same remark is applicable to the degree of thickness; but in forming a judgment on this point it is necessary to take the species into consideration. Though, as a general rule, very thin or very thick bark is of inferior quality, yet specimens have been found very effectual upon trial, which have not fallen within the limits usually considered the most proper in this respect. That which exceeds a line in thickness is not approved at Cadiz. The specific gravity of bark is also considered, in some measure, a criterion of its value, the heaviest being most esteemed. The fracture should be to a certain extent splintery; if sharp and short it indicates too great age; if the fibres are very long, there is reason to apprehend a want of maturity. The rolling of a bark affords another ground of judgment, though by no means to be relied on, as some excellent varieties are almost or quite flat. A feeble rolling indicates a bark too old or too slowly dried; a spiral form, one that has been gathered before it was ripe, or afterwards exposed to an improper degree of heat. The effects of heat are also observable in the darker colour of the bark, and the appearance of whitish stripes of a sickly hue, on the inside. Some dependence is placed by the South Americans upon the appearance of the epidermis; and the following commercial varieties have had their origin in this source:—1. *Negrilla,* blackish; 2. *crespilla,* crisped; 3. *pardo-obscura,* dark leopard-gray; 4. *pardo-clara,* bright leopard-gray; 5. *lagartijada,* silver or lizard coloured; 6. *blanquissima,* very white; and 7. *cenicienta,* ash-coloured. The first three are most esteemed. It is possible that among those well skilled in the subject, and thoroughly acquainted with the cinchona tree in its natural state, inferences may be drawn from these appearances, as to the elevation upon the mountains, the degree of exposure to the sun, and sometimes, perhaps, as to the species of the plant; but little reliance can be placed upon them by persons who are not already too well informed to need instruction.

The properties of colour, taste, and smell are more important. The colour which, according to Dr. Devoti, is most highly esteemed, is orange; and the gradations of shades from this to white mark a corresponding diminution in value. A dark colour between red and yellow is considered a sign either of inferiority in species, of improper preparation, or of injurious exposure to air and moisture. The taste should be bitter and very slightly acid, but not acrid, nauseous, nor very astringent. The odour is never very strong; but this quality exists in some degree in the better kinds of bark, and affords a favourable sign when it is decided and peculiar, without being disagreeable.

These remarks are of general application; they will be further extended, when the varieties of bark are separately described.

Classification.

To form a correct and lucid system of classification is the most difficult part of the subject of bark, which is throughout full of perplexities. An arrangement founded on the botanical species, though the most scientific and satisfactory when attainable, is in the present instance utterly out of the question. There are few varieties, of the precise origin of which we can be said to have any certain knowledge; by far the greater number being either derived from an unknown source, or but obscurely traceable to their native tree. Pharmaceutists indeed are not wanting, who are disposed to ascribe all the genuine barks, yielding quinia and cinchonia, to the same species of Cinchona. Guibourt has advanced the opinion, that they are all derived from varieties of the *C. lancifolia;* and adduces in support of it the statement of La Condamine, that when at Loxa he was informed, on good authority, that the trees yielding severally the yellow and red barks could not be distinguished by the eye. (*Journ. de Pharm.* xvi. 220.)

The Spanish merchants adopted a system of classification dependent partly on the place of growth or shipment, and partly on some inherent property or the supposed relative value of the bark. So long as the sources of the drug were very confined, and the number of varieties small, this plan answered the purposes of trade; but at present it is altogether inadequate; and though some of the names originally conferred upon this principle are still retained, they have ceased to be expressive of the truth, and are often erroneously, almost always confusedly applied. The *Loxa* barks embrace, among us, not only those which come from that province, but those also from the neighbourhood of *Huanuco;* while others, which have received different names, are brought from the same place. It is said that, by the traders in South America, the young slender gray barks are called by the name of Loxa, from whatever source they may be derived; while those somewhat larger and older receive their appellation from Lima.

Perhaps the best arrangement for pharmaceutical and medicinal purposes is that adopted in the United States Pharmacopœia, founded upon difference of colour. It is true that dependence cannot be placed upon this property alone; as barks of a similar colour have been found to possess very different virtues; and between the various colours considered characteristic, there is an insensible gradation of shade, so that it is not always possible to decide where one ends and the other begins. Still it has been found that the most valuable barks may be arranged, according to their colour, in three divisions, which, though mingling at their extremes, are very distinctly characterized, in certain specimens, by peculiarity not only in colour, but also in other sensible properties, and even in chemical constitution. The three divisions alluded to are the *pale*, the *yellow*, and the *red*. These may be considered as exclusively the officinal barks; while the inferior varieties which approach one or other of these classes in colour, but differ in other properties, may be treated as extra-officinal, and considered under a separate head. As these inferior kinds come chiefly if not exclusively from the northern ports of New Granada and Venezuela, they are known in commerce by the name of Carthagena barks, and by this name will be described in the present work. Specimens of little value may be occasionally imported from the Pacific coast of South America; but the quantity is small, as the profit they would yield would not pay the expense of so long a voyage. In describing, therefore, the different kinds of bark, we shall treat *first* of the officinal varieties under the three heads of *pale*, *yellow*, and *red*, and secondly of the extra-officinal under the title of *Carthagena barks*. The commercial name will at the same time be given in all instances in which a knowledge of it can be useful in this country. It is proper here to state, that the different barks frequently come to us mingled in the same package, and that, in deciding upon the character of a seroon, the druggist is guided rather by the predominance than the exclusive existence of certain distinctive properties.

1. Pale Bark.

The epithet *pale* applied to these barks is derived from the colour of the powder. The French call them *quinquinas gris*, or gray barks, from the colour of the epidermis. They come into the market in cylindrical pieces of variable length, from a few inches to a foot and a half, sometimes singly, sometimes doubly quilled, from two lines to an inch in diameter, and from half a line to two or three lines in thickness. The finest kinds are about the size of a goosequill. Their exterior surface is usually more or less rough, marked with circular and longitudinal fissures, and of a grayish colour, owing to the lichens which cover the epidermis. The shade is different in different samples. Sometimes it is a light gray, approaching to white, sometimes dull and brown, sometimes a grayish-fawn, and frequently diversified by the intermixture of the proper colour of the epidermis with that of the patches of lichens attached to it. The interior surface, in the finer kinds, is smooth and velvety; in the coarser, it is occasionally rough and somewhat ligneous. Its colour is uniformly a brownish-orange, sometimes inclining to red, sometimes to yellow; and in some inferior specimens is of a dusky hue. The product of the *C. lancifolia* of Bogota, probably received the name of orange-coloured bark from the appearance of its inner surface. The fracture is usually clear, with some short filaments on the internal part only. In the coarser barks it is more fibrous. The colour of the powder is a pale fawn, which is of a deeper hue in the inferior kinds. The taste is moderately bitter and somewhat astringent, without being disagreeable or nauseous. Authors speak also of an acidulous and aromatic flavour, which is less evident. The superior kinds have a feeble odour, which is distinct and agreeably aromatic in the powder and decoction. The pale barks are chemically characterized by containing *a much larger proportion of cinchonia than of quinia.* Their appearance indicates that they were derived from the smaller branches. They are collected in the provinces about Loxa, or in the country which surrounds the city of Huanuco to the north-east of Lima, and are probably derived chiefly from the C. Condaminea, C. scrobiculata, and varieties of the C. lancifolia.

In this country, the pale barks are all known in commerce by the general title of *Loxa bark*. The finest specimens are sometimes called *crown bark of Loxa*, a name also applied to them in England and Germany, and evidently derived from the impression, that they have the same origin and character with the bark formerly selected with great care for the use of the king of Spain and the royal family. It is probable, however, that the best of all the different kinds were appropriated to the royal use; and the honour was certainly possessed by the *yellow* as well as by the *pale*. The extension of the term *Loxa bark* to all the different varieties which belong to this class, is peculiar to the United States, and is not authorized by the facts of the case. They are not obtained exclusively from the province of Loxa, nor from the country bordering upon it. The French and Germans distribute them into several distinct divisions, originally named from the place of growth or export, but depending at present upon peculiarity in properties, without any geographical reference.[*]

[*] Since the publication of the first edition of this Dispensatory, we have had an opportunity of examining Von Bergen's splendid work upon bark, entitled *Versuch einer Monographie der China*, published in Hamburg in the year 1826. His descriptions are undoubtedly among the most precise and accurate which have been published, and we have availed ourselves of them in drawing up the following sketch of the varieties which may be arranged under the head of *pale bark*. We have also consulted, in relation to this subject, the works of the French pharmaceutical writers, particularly that of Guibourt, and the elaborate German work of Geiger, entitled *Hanbuch der Pharmacie, &c.* We have thrown our remarks into the form of a note, as the information in relation to these different varieties can be of little practical use to the student, though it may possibly serve to aid the discrimination of the druggist in the purchase of barks, by enabling him to decide on the relative value of the different parcels submitted to his notice.

1. *Loxa bark, Crown bark.—Quinquina de Loxa*, Fr.—*Loxa-China, Kron-China*, Germ.—This is in cylindrical tubes, strongly rolled, from six to fifteen inches long, from two lines to an inch in diameter, and from half a line to two lines thick. The outer surface is more or less rough, seldom much wrinkled longitudinally, but marked with numerous transverse fissures, which usually run round the bark, and divide it into rings, the edges of which are somewhat elevated. In the larger quills, these fissures are fewer, and more apt to be interrupted. The proper colour of the epidermis is dark-gray, sometimes almost black, sometimes ash-coloured, and occasionally inclining to fawn; but frequently diversified by whitish lichens, which are in some instances so numerous as to cover almost the whole exterior of the bark, and give it a light-gray appearance. The inner surface is smooth and uniform, and of the colour of cinnamon, with occasionally a reddish tinge. The fracture in the smaller quills is quite smooth, in the larger somewhat fibrous. The bark is of a rather firm consistence, and when cut transeversely exhibits a resinous character. Its odour is compared by Guibourt to that perceived in damp woods, by Von Bergen to that of tan. Its taste is acidulous, astringent, and bitterish. The powder is of a dull cinnamon colour. This variety of bark appears to contain, on an average of several results stated by Geiger, about 0.48 per cent. of cinchonia, and 0 06 of quinia. In the thicker pieces, which appear to be richest in the organic alkalies, Thiel found 1.0 per cent. of cinchonia, and 0.03 of quinia. The strong reaction of a solution of gelatin indicates the presence of much tannin. Guibourt describes two varieties of Loxa bark, one answering to the above, under the name of *Quinquina gris brun de Loxa*, the other under that of *Quinquina gris de Loxa*. The latter is characterized by its light-gray colour externally, and by its extreme thinness, which is observable even in the pieces taken from the larger branches. It is considered by this author as identical with the *cascarilla delgada* of Spanish commerce; and is very rare. The Loxa bark is thought to be derived chiefly from the *C. Condaminea*, and to have been the variety first imported into Europe. By some writers it is conjecturally ascribed in part to the *C. scrobiculata*.

2. *Lima or Huanuco bark.—Quinquina de Lima*, Fr.—*China Huanuco, Graue China*, Germ.—The Lima or Huanuco bark, was introduced into notice about the year 1779, after the discovery of Cinchona trees in the central regions of Peru. The first name originated from the circumstance that the bark entered into commerce through the city of Lima, the second was derived from the name of the city, (Huanuco or Guanuco,) in the more immediate neighbourhood of which the trees were found. The dimensions of this variety of bark do not materially differ from those of the preceding, although in the largest pieces the diameter is somewhat greater. Many of the smaller quills have a more or less spiral form. At the edge of most of the complete quills, a sharp oblique slit made with a knife is observable. The epidermis is usually adherent. The exterior surface is marked with longitudinal wrinkles, which in the thick pieces are often so

In this country, the pale bark appears to be falling into disuse; and the sales made by the druggists have, we are informed, been much diminished.

deep as to amount to furrows, penetrating quite through the outer coating of the bark. Transverse fissures are also generally observable, but they never run wholly round the quill, often not more than a quarter or half round, and do not exhibit elevated borders. In some pieces the outer layer of the epidermis is rubbed off either wholly or in spots, and in a few the entire thickness of the external layers, which we usually denominate the epidermis, is here and there removed, exhibiting the proper bark in patches. The colour externally is very light gray, almost milk-white, with occasionally bluish-gray and darkish spots intermingled. Where the outer crust which imparts this whitish colour is wanting, the surface is grayish-fawn or reddish-gray, and in the thicker pieces of a dark cinnamon colour. The inner surface, though in the smaller quills sometimes tolerably uniform, is generally more or less uneven, fibrous, or splintery, especially in the larger pieces, in which may often be observed adhering yellowish-white splinters of wood. The colour is usually a rusty-brown inclining somewhat to red, with occasionally a purplish tinge. The transverse fracture is smooth in the exterior part, fibrous or splintery in the interior. The longitudinal fracture is usually somewhat uneven, without being splintery, and exhibits here and there minute shining spots. The inner layers of the bark are usually soft and friable. The colour of the powder is a full cinnamon-brown. The odour of the bark is like that of clay, and in this respect different from that of all other varieties. The taste is at first acidulous, astringent, and slightly aromatic, and ultimately bitter and adhesive. The proportion of *cinchonia* contained in Huanuco bark, by an average of several results stated by Geiger, is 1.72 per cent,. of *quinia* 0.29 per cent. Von Santen got from the best specimens, as a maximum, 2.73 per cent. of cinchonia and no quinia. The most productive pieces are those of middling size. Guibourt makes two varieties of this bark, the *quinquina gris fin de Lima*, including the smaller quills, and the *quinquina gros Lima*, or *Lima blanc*, including the larger. The botanical origin of the bark is uncertain; but there is reason to believe that it is derived from the varieties of the *C. lancifolia*, described by Ruiz and Pavon.

3. *Jaen bark.—China Jaen, Blasse Ten-China*, Germ.—This is considered as a distinct variety only by the German writers. It probably derives its name from the province of Jaen de Bracomoros, in the vicinity of Loxa, where large quantities of bark have been collected. The Jaen bark is always in quills, which do not differ much in size from those of the Loxa bark, but are distinguishable by being frequently curved longitudinally, or bent in different directions, and somewhat spiral. The outer coat is often partially or entirely rubbed off, leaving the surface smooth and soft to the touch. When the epidermis is perfect, it exhibits small irregular transverse fissures, with occasionally faint longitudinal fissures and wavy wrinkles, and here and there a few warts, but no deep furrows. The colour varies from light or ash-gray to light yellow, diversified with blackish and brownish spots. When the outer coat is rubbed off, it inclines still more to yellow. Considered in mass, the bark always appears somewhat yellowish or straw-coloured. The exterior layers are soft and rather spongy, and may be readily scraped by the nail. The inner surface is exceedingly diversified, sometimes smooth, sometimes uneven and splintery. It is usually of a dull cinnamon colour. The bark is very brittle, and the fracture is smooth in the smaller quills, more or less uneven and sometimes splintery in the larger, and in neither exhibits a resinous appearance. The odour is somewhat sweetish, and is compared to that of tan. The taste is acidulous, slightly astringent, and bitter without being disagreeable. The colour of the powder is cinnamon-brown. In composition this bark resembles the Loxa and Huanuco, though it is said to contain less of the active principles. It is thought by Von Bergen to be derived from the *C. pubescens;* but nothing certain is known of its origin.

Von Bergen describes another variety of pale bark, under the name of *dark Jaen bark* (*Dunkele Ten-China*), or *Pseudo Loxa*, which bears a considerable resemblance to the genuine Loxa, but may be distinguished by the oblique or bent shape of the quills, and the uneven, fibrous, or even splintery appearance of the inner surface. It seldom comes in large pieces. It contains very little of the active principles of bark. Von Santen discovered neither quinia nor cinchonia in two specimens which he examined. Its general appearance, and strong reaction with a solution of gelatin, appear to associate it with the Loxa bark; and Geiger's conjecture is not improbable, that it is the product of the same tree growing in unfavourable situations, or altered by disease.

4. *Huamilies bark.—China Huamilies*, Germ.—This, like the preceding, is not generally known as a distinct variety, though probably identical with the *quinquina ferrugineux*, or ferruginous bark of the French writers. Its commercial name was undoubt-

As it yields little *quinia*, it is not employed in the manufacture of the sulphate of that alkali, which has almost superseded the bark as a remedy in intermittents; and the red bark is preferred by physicians, when it is necessary to resort to the medicine in substance. There is little doubt, however, that *cinchonia* possesses febrifuge properties little if at all inferior to those of *quinia;* and should the source of the latter begin to fail, the pale bark would come into more extensive use for the preparation of the former.

2. Yellow Bark.

The officinal term yellow bark should be considered as applicable only to the valuable variety of the drug having this colour. This is known in commerce under the name of *Calisaya*, said to be derived from a district of country in Bolivia, near the city of La Paz, where the bark is collected. Among the druggists, the Calisaya bark is arranged in two divisions, the quilled and the flat, which sometimes come mixed together in the same seroon, sometimes separate. The appearance of both indicates that they were taken from larger and older branches than those which yield the pale varieties. They are sometimes called by the French *quinquina jaune royal*, from their resemblance to a variety of bark formerly selected for the Spanish king.

The *quilled Calisaya, Calisaya arrolada* of the Spanish Americans, is in pieces from three or four inches to a foot and a half long, from a quarter of an inch to two or three inches in diameter, and of equally variable thickness. The epidermis is of a brownish colour diversified or concealed by whitish or yellowish lichens, is marked by longitudinal wrinkles and transverse

edly derived from the province of Huamilies, which lies in the interior of Peru, to the northward of Huanuco, and is a part of the country explored by the botanical expedition under Ruiz and Pavon. It came into notice in Germany about the beginning of the present century, when a parcel of it was imported directly from Lima into Hamburg. It is in quills and flat pieces. The quills are from three lines to an inch and a half in diameter, from five to sixteen inches long, and from half a line to three lines thick. The flat pieces, which are usually only fragments of the largest quills, are from one to two inches broad, and six to twelve inches long. In general all the layers of the bark are present, but sometimes the outer coat, and even the whole of that part usually called the epidermis in our descriptions of bark, (including those outer layers which in the tree are destitute of vitality, having been thrown outward by the annually renewed layers beneath them,) are wanting in spots, though very seldom entirely absent. The epidermis is comparatively thin, very brittle, soft, and spongy. The outer surface, in the small and middling quills, is sometimes nearly smooth, but usually marked with wavy longitudinal wrinkles, and beset here and there with warts. These warts are abundant upon the thick pieces, which they sometimes almost entirely cover. Transverse fissures are seldom found, and only in the thick pieces. The colour of the epidermis is usually grayish-fawn, here and there passing into a rusty brown; but in the thicker pieces, in which the warts are abundant, it is between a liver and chestnut colour, often mixed with a tinge of purple. When the epidermis is wanting, the colour is often a full ochre yellow. The inner surface is sometimes uniform and almost smooth, sometimes slightly fibrous, rarely splintery. The colour of the surface is rusty brown, occasionally reddish, and in the fibrous or splintery pieces of an ochre yellow. The fracture in the smaller quills is rather even, in the larger presents short fibres, and is sometimes even splintery. The odour of the bark is feeble but agreeable, the taste somewhat aromatic, bitterish, and slightly astringent. The powder is of a full cinnamon colour. The average product of cinchonia and quinia, as stated by Geiger, is 0.67 per cent. of the former, and 0.25 of the latter, so that the bark, though dissimilar in appearance from the other varieties of pale bark, agrees with them in containing more cinchonia than quinia. Von Santen obtained, as a maximum, 1.2 per cent. of cinchonia, and little or no quinia.—*Note to Second Edition.*

fissures, and is often partially separated, and generally easily separable from the proper bark. In the larger kinds it is thick, rough, deeply indented by the transverse fissures which often surround the quills, and is composed of several layers separated from each other by a reddish-brown membrane like velvet. This epidermis yields a dark red powder, is tasteless, and possesses none of the virtues of the bark. It is desirable, therefore, to get rid of it before the bark is powdered, as the medicine is thus procured of greater strength. The bark itself, without the epidermis, is from one to two lines in thickness, of a fibrous texture, and when broken presents shining points, apparently the termination of small fibres running longitudinally, which, examined by the microscope, are found, when freed from a salmon-coloured powder that surrounds them, to be yellow and transparent. They readily separate when the bark is powdered, in the form of spiculæ, which, like those of the cowhage, insinuate themselves into the skin, and produce a disagreeable itching and irritation. The colour of the bark is yellow with a tinge of orange, the taste less astringent than that of the pale bark, but much more bitter and more nauseous. The external cortical layers are more bitter and astringent, and consequently stronger in medicinal power, than the internal; probably from the longer exposure of the latter to the action of air and moisture. The odour is faint, but when the bark is boiled resembles that of the pale varieties. The small quills closely resemble some of the pale varieties in appearance, but may be distinguished by their very bitter taste.

The *flat Calisaya*, *Calisaya plancha* of the Spaniards, which appears to have been derived from the large branches and trunk, is in pieces of various lengths, either quite flat, or but slightly curved, generally destitute of the epidermis, and therefore presenting the yellowish colour of the bark both within and without. It is usually thicker than the quilled, more fibrous in its texture, less compact, less bitter, and possessed of less medicinal power. Though weaker than the proper bark of the quills, it is usually, in equal weight, more valuable than that variety, because free from the useless epidermis.

The valuable yellow bark is characterized by its strongly bitter taste, with comparatively little astringency; by its fine brownish-yellow somewhat orange colour, which is still brighter in the powder; and by *containing a large proportion of quinia with very little cinchonia.* The salts of quinia and lime are so abundant in its composition, that its infusion instantly precipitates a solution of sulphate of soda. (*Guibourt*).*

---

* The Calisaya bark is the third variety of Von Bergen, who describes it under the name of *China Regia* or *König's China.* We give a brief abstract of his description, omitting the form and dimensions, which are given with sufficient minuteness in the text. The epidermis,† which in many of the small quills is partly wanting, in the flat pieces usually altogether absent, is very thick and brittle, constituting from a third to one-half of the bark, and in some of the largest quills, or partially quilled pieces, even two-thirds. In the latter case it may often be seen to consist of six or eight different layers. The quills are generally marked with longitudinal wrinkles and furrows, as well as with transverse fissures, the last of which are never absent. The fissures, which often form complete circles round the quills, have usually an elevated border, and sink so deeply in many of the larger pieces, that they are even observable upon the proper bark. In the smaller pieces they are often faint, but usually crowded. The colour of the epidermis varies from

† By the epidermis is here understood the whole of the external layers which are accumulated upon the outer surface of the bark by the annual renewal of the cortical layers, and the consequent separation of those of former years, which remain, but without life, attached to the external surface. A different meaning is attached to the term by Von Bergen, but as we have taken pains to make the description in every instance correspond with our definition, we do not misrepresent his meaning.

Authors are by no means agreed as to the particular species which yields Calisaya bark. Some, influenced simply by its officinal title of yellow bark, have attributed it to the *C. cordifolia*, because Mutis gave the same name to the product of this species. The British Colleges have fallen into this error, without, however, being aware that the yellow bark which they adopted as officinal was really the Calisaya. That it is an error has been fully demonstrated; as no *Calisaya bark* is brought from those regions where the C. cordifolia most abounds. Many writers ascribe this variety to the *C. lancifolia*, on the authority of Mutis himself, who asserts that it is indisputably derived from that species.* This may possibly be the case; and the supposition of M. Guibourt may be true, that the officinal pale, yellow, and red barks are all derived from varieties of the C. lancifolia; but we have no precise information on the subject; and Ruiz himself acknowledges that he is unacquainted with its source.† A curious mistake on this subject is made by Dr. A. T. Thomson in his Dispensatory. Considering the *C. lancifolia* as undoubtedly the origin of the *pale bark*, and at the same time receiving without hesitation the assertion that the *Calisaya* is the product of this species, he has inferred that the two must be identical; and has therefore given Calisaya as one of the synonymes of pale bark; while he has accurately described the true *Calisaya*, but without naming it, under the head of C. cordifolia or yellow bark.

The genuine Calisaya bark is produced most abundantly in Bolivia, formerly Upper Peru, in the province of La Paz; and before the disturbances in these countries, was shipped as well from the port of Buenos Ayres as from those on the Pacific. It is at present, however, procured exclusively from the latter. A very fine parcel was exhibited to us, imported directly from Coquimbo in Chili. We have been informed by gentlemen who have been long personally engaged in commercial transactions upon the Pacific

---

whitish-gray to bluish-gray, but is very much diversified by lichens, so as to present yellowish-white, ash-gray, and blackish spots. When the outer layer of the epidermis is wanting, as is not unfrequently the case to a greater or less extent, the colour is somewhat sooty-brown, or almost liver-brown. The outer surface of the pieces without epidermis, is of a colour between cinnamon-brown and dark rusty-brown. The inner surface, in the pieces of all dimensions, is uniform and almost smooth, but exhibits fine longitudinal fibres closely compressed. Splinters of wood are never found adhering to the inner surface, as in some other varieties. The prevailing colour of this surface is mostly a rather dark or full cinnamon-brown, passing sometimes into a rusty-brown, but seldom of a reddish hue. This bark breaks more easily in the longitudinal direction than any other variety, exhibiting a chestnut-brown colour in the part answering to the epidermis, a more or less dark cinnamon-brown in that answering to the proper bark. The transverse fracture of the epidermis is rather even, that of the inner part sometimes fibrous, sometimes splintery. A resinous layer may be observed beneath the epidermis, which usually remains when the latter is removed, and communicates to the flat pieces the dark colour by which their external surface is distinguished. Small sharp splinters, which in the longitudinal fracture appear like shining points, are apt to insinuate themselves into the skin, when the bark is broken or much handled. The odour is feebly tan-like, the taste slightly acidulous, strongly but not disagreeably bitter, somewhat aromatic, feebly astringent, and rather durable. The powder is of a fine cinnamon hue.

Thiel obtained from the flat Calisaya bark 2.3 per cent. of quinia, and 0.08 of cinchonia; *Michaelis* from the flat 3.7 per cent., and from the quill 2.0 per cent. of quinia, but no cinchonia from either; *Von Santen* from the flat, an average of 2.0 per cent. of quinia, and little or no cinchonia; *Wittstock*, on an average, 3.0 per cent. of sulphate of quinia, and 0.12 of cinchonia.—(*Geiger.*)—*Note to Second Edition.*

* Humboldt's "Characteristics of some species of Cinchona." See *Lambert's Illustration*, 1821, p. 53.

† He says, however, that it may be derived from the C. lanceolata, which is now acknowledged to be the same species with the C. lancifolia. (*Memoir by M. Laubert.*) See *Lambert's Illustration*, p. 70.

coast of South America, that the Calisaya bark of commerce is originally obtained chiefly, if not exclusively, at the port of Arica, whither it is brought from the interior provinces of Bolivia. From that town it is sent to various other ports on the Pacific. It is generally supposed to have been first introduced into commerce towards the end of the last century, and it was probably not known by its present name till that period; but La Condamine states that the Jesuits of La Paz, at a period anterior to the discovery of the febrifuge of Loxa, sent to Rome a very bitter bark by the name of *quinaquina,* which, though supposed by that traveller to have been derived from the Peruvian balsam tree, was very probably, as conjectured by Guibourt, the true cinchona. Besides, Pomet, in his *History of Drugs,* published in 1694, speaks of a bark more bitter than that of Loxa, obtained from the province of Potosi, which borders upon that of La Paz; and Chomel also states, that the cinchona tree inhabited the mountains of Potosi, and produced a bark more esteemed than that which grew in the province of Quito. (*Guibourt, Journ. de Pharm.* xvi. 235.) It is possible that, though known at this early period, it may have gone out of use; and its re-introduction into notice towards the end of the last century, may have been mistaken for an original discovery. Whether it is found in the other localities of bark in Peru and Quito, it is difficult to determine; but we may infer from the existence of a commercial variety known to the Spaniards by the name of *Calisaya de Quito,* that either the identical bark, or a variety closely analogous to it, has been found in that province. The *Calisaya de Santa Fe* mentioned by Laubert, has no other claim to the title given it than its colour; and it is not distinguished in the market, perhaps not distinguishable from the ordinary yellow Carthagena bark.

3. RED BARK.

The name of this variety is very appropriately applied, as the colour is usually distinct both in the bark and the powder. In South America it is called *cascarilla roxa* and *colorada.* Some writers have divided it into several sub-varieties; but there does not seem to be ground for such division in any essential difference of properties. Like the *Calisaya,* it comes in quills and flat pieces, which are probably derived from different parts of the same tree.

Some of the pieces are entirely rolled, some partially so, as if they had been taken from half the circumference of the branch; others are nearly or quite flat. They vary very greatly in size, the quill being sometimes less than half an inch in diameter, sometimes so much as two inches, while the flat pieces are occasionally very large and thick, as if derived from the trunk of a tree. They are covered with a reddish-brown or gray, sometimes whitish epidermis, which is rugged, wrinkled longitudinally, and in the thicker pieces marked with furrows, which in some places penetrate to the surface of the proper bark. In many specimens, numerous small roundish or oblong eminences, called warts, may be observed upon the outer surface. Beneath the epidermis is a layer, dark red, brittle, and compact, which possesses some bitterness and astringency, but much less than the interior parts. These are woody and fibrous, of a more or less lively red colour, which is usually very distinct, but in some specimens passes into the orange and even yellowish-brown, so that it is not always possible to distinguish the variety by this property alone. The taste is bitter and astringent, and the odour similar to that of other good barks. Red bark is chemically distinguished by *containing considerable quantities both of quinia and of cinchonia.**

Till very recently, it has been almost universally admitted, on the authority of Mutis, that the red bark was the product of the *C. oblongifolia* of that author, and the *C. magnifolia* of the Flora Peruviana, which is generally supposed to be the same species with the former. But it is now well understood that the *red bark of Santa Fe*, the real product of the *C. oblongifolia*, has little else in common with the true officinal red bark than its colour, and belongs properly to the Carthagena barks. This might have been conjectured from the fact, that none of the best red bark is brought from the Atlantic ports of New Granada, through which the product of the *C. oblongifolia* must at least in part, be sent out of the country. But Von Bergen is the first author who has satisfactorily shown, that the genuine red bark of commerce is not derived from this species. The proofs advanced by him are the following. A specimen of the bark of the *C. oblongifolia*, given by Humboldt to Schrader, was found to be the *quina nova* of commerce, and to bear no resemblance to the genuine red bark; and Humboldt aknowledged to this gentleman, that he was unacquainted with the tree which yields the latter. Ruiz and Pavon, also, though they frequently mention the red bark, agree in stating that they are ignorant of its source; and in the supplement to the Quinologia, mention that the red bark from the *C. oblongifolia* is wholly different from the commercial variety which bears that name. Besides, in the collection belonging to Ruiz, were specimens of the bark of the *C. oblongifolia*, designated by the name of *quina azahar o roja de Santa Fe*, which were entirely different from the genuine red bark, while they bore an exact resemblance to the *quina nova*. These arguments of Bergen are still further strengthened by the testimony of Guibourt, who states that a specimen of the red bark of Mutis, the product of his *C. oblongifolia*, which had been presented by this botanist to Humboldt, and by him deposited in the botanical cabinet of the *Jardin du Roi*, was found upon examination scarcely to differ from that known in commerce by the name of *quina nova*. This *quina nova* is an inferior kind of Carthagena bark, of a red colour, formerly supposed to be furnished by the *Portlandia grandiflora*, and containing little or no quinia or cinchonia. It appears, therefore, that the valuable red bark is not derived from the *C. oblongifolia*, and that nothing is certainly known as to its source. There is some reason to believe that it may be derived from the same species with the pale barks, but taken from the larger branches or the trunk. This opinion receives some support from a statement made by La Condamine, in his memoir upon the subject of cinchona. We are told by this author that three kinds of bark were known in the neighbourhood of Loxa—the white, the yellow, and the red. The white, so named from the colour of the epidermis, scarcely possessed any medicinal virtue, and was obtained from a tree entirely distinct from that which yielded the two other varieties. The red was superior to the yellow; but he was assured, on the very best authority, that the trees producing them grew together, and were not distinguishable by the eye. Of the three varieties mentioned by La Condamine, the white does not reach us; and that which he calls yellow is probably identical with the pale variety of the Pharmacopœia, as this grows most abundantly about Loxa, and before being powdered is often of a yellowish colour. Should it be admitted that the red bark is furnished by the same tree which yields the pale, we have a ready explanation of the difference in size of the two varieties.

---

* The red bark is given as a distinct variety by Von Bergen, and stands first on his list, under the name of *China rubra* or *rothe China*. The following is an abstract of his description.

The quills are from two lines to an inch and a quarter in diameter, from one-third of a line to two lines thick, and from two to twelve inches or more in length. The smaller quills are often spiral. The flat pieces are from one to two inches broad, from three-eighths to a quarter of an inch thick, and of the same length as the quills. In the smaller and middling-sized quills, the external surface exhibits longitudinal wavy wrinkles. In the thicker pieces, these wrinkles, between which are here and there longitudinal furrows, often elevate themselves into roundish or oblong warts, which are of a somewhat friable and granular consistence. The longitudinal furrows sometimes penetrate to the bark. Transverse fissures seldom occur. The colour in the smaller quills varies from a fawn-gray to a dull reddish-brown, in the larger is reddish-brown or chestnut-brown with a tinge of purple. When the wrinkles and warts are rubbed off, the peculiar brownish-red colour of the bark appears. The pieces are often in part or almost wholly covered with a whitish-gray or yellowish-white coat, either belonging to the epidermis or consisting of lichens. In some of the quills the epidermis is wanting in spots, which exhibit a dirty reddish-cinnamon colour. The inner surface is delicately fibrous and almost uniform in the small quills, but becomes more fibrous and uneven in the larger, and in the flat pieces is splintery and very irregular. Its colour varies with the size of the pieces, being a reddish-rusty brown in the least, redder in the larger, and a full brownish-red in the largest. The inner surface is also sometimes yellowish, or brownish, or of a dirty appearance. It becomes darker when scraped with the nail or other hard body. The fracture exhibits the different colours of the epidermis and inner bark, as also of a resinous layer which lies between the two. It is usually even in the smaller quills, fibrous in the larger, and at the same time fibrous and splintery in the largest and flat pieces. The fracture of the epidermis, however, is in all either even, or only here and there somewhat granular. The odour is like that of tan and earthy, the taste strongly but not disagreeably bitter, somewhat aromatic, and not lasting. The powder is of a dull brownish-red colour.

Experiments upon many different specimens of red bark, as stated by Pfaff, give as an average result 1.7 per cent. of pure cinchonia, and 0.44 of sulphate of quinia. The highest product obtained was 3.17 per cent. of cinchonia, and 0.15 of sulphate of quinia. Another specimen yielded 1.21 per cent. of the former, and 1.33 of the latter. Pelletier and Caventou obtained 0.8 per cent. of cinchonia, and 1.7 of quinia. (*Geiger.*) It appears, therefore, that the proportion of the alkalies is exceedingly different in different specimens. The degree of bitterness is, perhaps, the best criterion of their efficacy.

Guibourt divides the red bark into two varieties, which he distinguishes by the name of *quinquina rouge verruqueux*, and *quinquina rouge non verruqueux*, from the presence or absence of the warts upon the outer surface. He admits also as a variety, the *quinquina rouge de Santa Fe* of M. Laubert, which ought, if it is properly named, to be placed among the Carthagena barks, and from its want of bitterness might very properly be associated with the red Carthagena bark.—*Note to Second Edition.*

Carthagena Barks.

Under this head may be classed all the barks brought from the northern Atlantic ports of South America. Like those of Peru and Quito, they may be arranged in several subdivisions characterized chiefly by peculiarities of colour. 1. The most abundant is the *yellow Carthagena bark*, which comes in fragments of various sizes, from one to three or even five lines in thickness, usually covered wholly or in part with a white epidermis. The bark itself is of a yellow colour, spongy under the teeth, and of a bitter nauseous taste. It is probably obtained from the *C. cordifolia*, as Guibourt found that a specimen of the bark of this tree, which came originally from Mutis, resembled it precisely in all its sensible properties.* 2. Another

---

* Von Bergen considers the Carthagena barks under the two divisions of 1. *China flava dura*, or *harte gelbe China*, and 2. *China flava fibrosa*, or *holzige gelbe China*. As these, with the varieties before noticed as described by him, complete the nine divisions under which he ranks the barks of commerce, we shall give a brief abstract of his account of them. They are both included under the title of *yellow Carthagena bark*, as given in the text.

1. *China flava dura, or hard yellow bark.*—This is in quills and flat pieces. The quills

variety may be called the *brown Carthagena bark.* This also has a white epidermis, which is smooth and without fissures. The bark is hard, compact, very heavy, rough and thick, of a chocolate colour internally, and of a bitter and astringent taste, more disagreeable than that of the pale barks, to which it is in other respects somewhat analogous. Its source is unknown. 3. A third variety is the *red Carthagena bark*, distinguished from the officinal *red bark* by its whitish smooth epidermis, and by its comparatively feeble taste. It is probably derived from the *C. oblongifolia*, and is not known in this country as a distinct variety. 4. Within a few years a variety

---

are from three to eight lines in diameter, from half a line to a line and a half thick, and from five to nine inches, and sometimes, though rarely, even fifteen inches long. The flat pieces are considerably thicker, from half an inch to two inches broad, and from four to eight in length. They are often somewhat twisted, and so curved in the drying that the upper surface is rather concave. The epidermis is in many pieces partially or almost wholly wanting. The outer surface is on the whole rather smooth, though it usually exhibits a few faint longitudinal furrows and transverse fissures, and pieces are occasionally found with hard warts or protuberances. In the flat pieces, the epidermis, when present, has somewhat of the consistence of cork, and consists of several layers. The colour of the epidermis varies from yellowish-white to ash-gray, and is sometimes diversified by bluish-gray or blackish lichens. When it is wanting, the colour is between a dark cinnamon and brownish-yellow. These shades, however, are seldom clear, and the flat pieces have usually a somewhat dusty aspect. The inner surface of the quills is tolerably uniform, that of the flat pieces uneven or faintly furrowed and even splintery, the points of the splinters often projecting. Its colour, which is almost always dull, as if the surface were dusty, varies between a light cinnamon and a dull ochre-yellow, and in some pieces is rusty-brown or fawn-gray, or even whitish-yellow. The bark does not readily break in the longitudinal direction. The transverse fracture presents short splinters, and is sometimes fibrous. When cut transversely, the bark obscurely exhibits a very small darker coloured resinous layer beneath the epidermis. The odour is feeble, the taste slightly astringent and bitter, but not strongly so. The powder is of the colour of cinnamon. Von Bergen attributes this variety to the C. cordifolia.

2. *China flava fibrosa*, or *woody yellow bark.*—The shape and dimensions of this variety do not materially differ from the preceding; but the flatter pieces are almost always a little rolled, or curved laterally. The epidermis is seldom entire, being in general either in part or wholly rubbed off. When present, it resembles in consistence that of the former variety. Its outer surface is nearly smooth, only marked here and there with faint irregular transverse fissures and longitudinal furrows. Its colour varies from a dirty whitish-gray to yellowish, but is sometimes more or less dark. When the outer surface is rubbed off, as is the case here and there in the quills, and almost always in the flat pieces, the colour is a nearly pure ochre-yellow. Where the whole thickness of the epidermis is wanting, as happens here and there in spots, it is dark cinnamon, or dark ochre-yellow, and commonly dull or powdery. The inner surface is usually even, but is sometimes irregular and splintery, and always feels harsh to the fingers, leaving small splinters sticking in the skin when drawn over it. The colour is a nearly pure ochre-yellow, like that of the external surface when the outer layer is rubbed off, though somewhat duller and very powdery. The fracture distinguishes this variety from the preceding and from all others. The longitudinal fracture is strikingly fibrous, and in the flat pieces the fragments still hang together by connecting fibres. The bark, moreover, breaks obliquely, and the fracture even of the epidermis, which in other varieties is almost always smooth, is here uneven or rough-grained. The transverse fracture exhibits very long and thin splinters or fibres, which are very flexible, and may almost be said to be soft. No traces of a resinous appearance are observable in the fracture. The odour is feeble, the taste at first woody and flat, afterwards slightly bitter and astringent, and weaker in this than in any other variety of bark. The colour of the powder is intermediate between that of cinnamon and yellow-ochre. The tree from which this variety is obtained is unknown.

Of these two varieties of Carthagena bark, the first yielded, on an average of two experiments, 0.57 per cent. of pure cinchonia, and 0.33 per cent. of sulphate of quinia; the second yielded, on an average of five trials with different specimens, 0.4 per cent. of pure cinchonia, and 0.36 of sulphate of quinia. The highest product of the fibrous bark was about 0.59 per cent. of cinchonia, and 0.52 of sulphate of quinia. From this statement, it appears, that so far as regards the relative proportion of their two active ingredients, they should rank with the red bark, though greatly inferior to it in strength.

has appeared in our market under the name of *Santa Martha bark*, which ranks itself by its characters among those of Carthagena. It derives its name from the port where it is shipped. It is either in small irregularly oblong fragments, flat or but slightly curved, from one to three lines in thickness, usually destitute of epidermis, and presenting an appearance somewhat as if chipped from the large branches or trunk of the tree; or in short quills, partially covered with a whitish epidermis, and evidently derived from the smaller branches. This bark is compact, of a pale yellowish colour, and a bitter, somewhat nauseous taste. It is usually considered superior to the ordinary Carthagena bark, probably from its greater bitterness. May it not be derived from the *C. macrocarpa*, the *C. ovalifolia* of Mutis, which Humboldt informs us grows in the neighbourhood of Santa Martha?

All the Carthagena barks, as will have been observed, have a white somewhat micaceous epidermis. They are also distinguished by a taste less bitter and more nauseous than that of the officinal varieties; and, though they contain more or less quinia and cinchonia, are by no means abundant in these principles.

FALSE BARKS.

Before dismissing the subject of the varieties of cinchona, it is proper to observe, that numerous barks have at various times been introduced into the market, and sold as closely resembling or identical with the febrifuge of Peru, which experience has proved to differ from it materially, both in chemical composition and medicinal virtues. These barks are generally procured from trees which were formerly ranked among the Cinchonæ, but are now arranged in other genera. They are distinguished from the true Peruvian bark by the absence of quinia and cinchonia. Among them are 1. the *Caribæan bark*, from the Exostemma Caribæa; 2. the *St. Lucia bark*, or *quinquina piton* of the French, derived from the Exostemma floribunda; 3. the *Pitaya bark*, known in France by the name of *quinquina bicolor*, supposed by some to be derived from an Exostemma, by others from the Strychnos pseudo-quina; and 4. the bark called on the continent of Europe *new bark* (quina nova), which, though generally ranked with the false barks and considered as the product of the *Portlandia grandiflora*, is believed by some pharmaceutists to be the same with the red bark of Mutis, and should therefore be considered identical with the red Carthagena bark. Most of these barks are scarcely known in the commerce of this country; not one of them is used in our medical practice; and they are mentioned in this place only that the student, when he meets with their names in other works, may know where to refer them.

Chemical History.

In the analysis of Peruvian bark, the attention of chemists was at first directed exclusively to the action of water and alcohol upon it, and to the determination of the relative proportion of its gummy or extractive and resinous matter. The presence of tannin and of various alkaline or earthy salts in minute quantities was afterwards demonstrated. Fourcroy made an elaborate analysis, which attracted much attention at the time, and proved the existence of other principles in the bark than those previously ascertained; but the results which he obtained were not very definite. Dr. Westring was the first who attempted the discovery of an active principle in the bark on which its febrifuge virtues might depend; but he was unable to carry out his conception to any successful result. Seguin afterwards pursued the same track, and endeavoured, by observing the effects of various re-agents to discover the relative value of different varieties of the drug. The conclusions, however, at which he arrived, have not been supported by subsequent experiment. M. Deschamps, an apothecary of Lyons, obtained from bark a crystallizable salt of lime, the acid of which Vauquelin afterwards separated, and called *kinic acid*. The latter chemist also pushed to a much further extent the researches of Seguin, as to the influence of reagents. He examined seventeen different kinds of bark, which he arranged in three classes, according to their chemical relation with certain reagents—the *first* class including those which afforded precipitates with tannin and not with gelatin; the *second*, those which precipitated gelatin and not tannin; the *third*, those which precipitated at the same time tannin, gelatin, and tartar emetic. He supposed those to be the most efficient which gave precipitates with tannin or the infusion of galls; but his classification has been abandoned with the progress of discovery. Reuss of Moscow succeeded in isolating a peculiar colouring matter from red bark, which he designated by the name of *cinchonic red;* and obtained a bitter substance, which probably consisted in part of the peculiar alkaline principles, subsequently discovered. The first step, however, towards the discovery of cinchonia and quinia appears to have been taken by the late Dr. Duncan of Edinburgh. He believed the precipitate afforded by the infusion of cinchona with that of galls, to be a peculiar vegetable principle, and accordingly denominated it *cinchonine.* Dr. Gomez, a Portuguese physician, convinced that the active principle of bark resided in this cinchonine, but in an impure state, instituted experiments upon some pale bark, which resulted in the separation of a white crystalline substance, considered by him to be the pure *cinchonine* of Dr. Duncan. It was obtained by the action of potassa upon an aqueous infusion of the alcoholic extract of the bark, and was undoubtedly the principle now universally known by the name of *cinchonine* or *cinchonia*. But Dr. Gomez was ignorant of its precise nature, considering it to be analogous to resin. M. Laubert afterwards obtained the same principle by a different process, and described it under the name of *white matter* or *pure white resin*. To Pelletier and Caventou was reserved the honour of crowning all these experiments, and applying the results which they obtained to important practical purposes. They demonstrated the alkaline character of the principle discovered by Gomez and Laubert, and gave it definitively the name of *cinchonine*. They discovered in the yellow or Calisaya bark another alkaline principle, which they denominated *quinine*. Both these bases they proved to exist naturally in the barks, combined with the *kinic acid* in the state of *kinate of cinchonine and of quinine*. It has moreover been established by their labours, that the febrifuge property of bark depends upon the presence of these two principles. It was in the year 1820 that these chemists announced their discovery. Dr. Duncan's suggestion was made so early as 1803. Among English and American chemists, the names of these alkaline bodies have been changed to *cinchonia* and *quinia*, for the sake of uniformity of nomenclature; and by these names we shall always call them.

It has before been stated, on more than one occasion, that the three officinal varieties of bark are distinguished by peculiarities of composition. We give the result of the analysis of each variety as obtained by Pelletier and Caventou. (*Journ. de Pharm.* vii. 70. 89. 92.)

Pale bark of Loxa contains, 1. a fatty matter, discovered by Laubert; 2. a red colouring matter, very slightly soluble, identical with the cinchonic red of Reuss; 3. a yellow colouring matter, observed by Laubert, soluble in water and alcohol, and capable of being precipitated by the subacetate of lead; 4. tannin; 5. gum; 6. starch; 7. lignin; 8. kinate of lime; 9. *kinate of cinchonia, with a very minute proportion of kinate of quinia.*

Yellow Calisaya bark contains the fatty matter, the cinchonic red, the yellow colouring matter, tannin, starch, lignin, kinate of lime, and *acidulous kinate of quinia, with a comparatively small proportion of kinate of cinchonia.*

Red bark contains the fatty matter, a large quantity of the cinchonic red, the yellow colouring matter, tannin, starch, lignin, kinate of lime, and *a large proportion both of acidulous kinate of quinia, and of acidulous kinate of cinchonia.*

Carthagena bark contains the same ingredients with the red bark, but in different proportions. It has less of the alkaline matter, which it also yields with much greater difficulty to water, in consequence of the abundance of insoluble cinchonic red which it contains, and which either involves the salts of quinia and cinchonia so as to prevent the full contact of water, or retains these alkalies in a species of combination. (*Journ. de Pharm.* vii. 105.)

By the experiments of Henry Jun. and Plisson, it may be considered as established, that the alkalies of the different varieties of bark are combined at the same time with kinic acid, and with one or more of the colouring matters, which, in relation to these substances, appear to act the part of acids. This idea was originally suggested by Robiquet. (*Journ. de Pharm.* xiii. 282. 369.) It is stated that the compounds of quinia and cinchonia with the cinchonic red are scarcely soluble in water, while the kinates of these bases are very soluble. (Ibid. xvii. 201.)

From the statements above made it appears, that the three officinal varieties of bark differ little, except in the proportion of their constituents. All contain both quinia and cinchonia; the yellow bark abounding in the first, the pale in the second, and the red in both. Gum is the only constituent found in one and not in the others. It is an ingredient in the pale bark, but is wanting in the red and yellow. The observations which follow on the peculiar and characteristic properties of the proximate principles of bark, are derived chiefly from the Memoir of Pelletier and Caventou, published in the 7th volume of the *Journal de Pharmacie.* It may be proper to mention, that MM. Pelletier and Coriol have discovered a new alkaline principle, called *aricina*, in a bark brought from Arica on the Pacific coast of South America, fraudulently mixed with the Calisaya bark.

The *fatty matter*, which was first obtained pure by M. Laubert, is of a greenish colour as obtained from the pale bark, orange-yellow from the yellow. It is insoluble in water, soluble in boiling alcohol, which precipitates a part of it on cooling, very soluble in sulphuric ether even cold, and capable of forming soaps with the alkalies. The colour is probably owing to extraneous matter connected with it.

The *cinchonic red* of Reuss, the *insoluble red colouring matter* of Pelletier and Caventou, is reddish-brown, insipid, inodorous, largely soluble in alcohol, especially when hot, and almost insoluble in ether or water, though the latter dissolves a little at the boiling temperature. The acids promote its solubility in water. It precipitates tartar emetic, but not gelatin; but if treated with a cold solution of potassa or soda, or by ammonia, lime, or baryta with heat, and precipitated by an acid from the solution thus formed, it acquires the property of forming an insoluble compound with gelatin, and seems to be converted into a species of tannin. It is precipitated by subacetate of lead. It is most abundant in the red bark, and least so in the pale.

The *yellow colouring matter* has little taste, is soluble in water, alcohol, and ether, precipitates neither gelatin nor tartar emetic, and is itself precipitated by subacetate of lead.

The *tannin*, or *soluble red colouring matter* of Pelletier and Caventou, has all the properties which chemists consider distinctive of the proximate vegetable principles associated together under this name. It has a brownish-red colour and austere taste, is soluble in water and alcohol, combines with metallic oxides, and produces precipitates with the salts of iron, which vary in colour according to the variety of bark; being deep green with the pale bark, blackish-brown with the yellow, and reddish-brown with the red.

But the most interesting and important constituents of Peruvian bark are the cinchonia and quinia, and the acid with which they are combined. In relation to these, therefore, we shall be more minute in our details.

Cinchonia when pure is a white crystalline substance, soluble in two thousand five hundred parts of boiling water, almost insoluble in cold water, very soluble in boiling alcohol which deposites a portion in the crystalline state upon cooling, and slightly soluble in ether and the fixed and volatile oils. Its bitter taste, at first not very obvious in consequence of its difficult solubility, is developed after a short time by the solution of a minute portion in the saliva. Its alcoholic, ethereal, and oleaginous solutions are very bitter. Its alkaline character is very decided, as it neutralizes the strongest acids, forming with them saline compounds. Of the salts of cinchonia, the sulphate, nitrate, muriate, phosphate, and acetate are soluble in water. The neutral tartrate, oxalate, and gallate are insoluble in cold water, but may be dissolved in hot water or in alcohol. Several processes have been employed for the preparation of cinchonia. One of the simplest is the following. Powdered pale bark is submitted to the action of sulphuric or muriatic acid very much diluted, and the solution thus obtained is precipitated by an excess of lime. The precipitate is collected on a filter, washed with water, and treated with boiling alcohol. The alcoholic solution is filtered while hot, and deposites the cinchonia when it cools. A further quantity is obtained by evaporation. If not perfectly white, it may be freed from colour by first converting it into a sulphate with dilute sulphuric acid, then treating the solution with animal charcoal, filtering, precipitating by an alkali, and redissolving by alcohol in the manner already mentioned. Cinchonia consists, according to Pelletier and Dumas, of 76.97 parts of carbon, 9.02 of nitrogen, 6.22 of hydrogen, and 7.79 of oxygen; and its equivalent number appears, from the analysis of its sulphate by Pelletier and Caventou, to be 307.196, hydrogen being considered as unity. Liebig states the equivalent at 160.4; but this chemist supposes the sulphate of cinchonia, usually considered neutral, to consist of two equiv. of base and one of acid. Exposed to the air cinchonia does not suffer decomposition, but very slowly absorbs carbonic acid, and acquires the property of effervescing slightly with acids.

Sulphate of cinchonia, the only salt of this base which has been employed to any extent in a separate state, may be prepared by heating the cinchonia with a little water, adding dilute sulphuric acid gradually till the alkali is saturated, then boiling with animal charcoal previously washed with muriatic acid, filtering the solution while hot, and setting it aside to crystallize. By alternate evaporation and crystallization, the whole of the sulphate may be obtained from the solution. It is a white, very bitter salt, crystallizing in flexible, somewhat shining, four-sided, flattened prisms, terminated by an inclined face, and generally collected in fasciculi; soluble in fifty-four parts of water at common temperatures, and in a smaller quantity of boiling water; and passing, by the addition of the necessary quantity of acid, into a bisulphate, which is soluble in less than half its weight of water at 58°. It consists, according to Pelletier and Caventou, of 100 parts of cinchonia, and 13.021 of sulphuric acid. (*Journ. de Pharm.* vii. 57.)

Quinia is whitish, and as usually prepared is rather flocculent in its appearance, not crystalline like cinchonia. It may, however, be crystallized, by cautious management, in pearly silky needles. (*Journ. de Pharm.* xi. 249.) It is fusible like the resins, and becomes brittle on cooling. It is more bitter than cinchonia, is almost insoluble in water, but is very soluble in alcohol, and soluble also in ether, and in the fixed and volatile oils. Its alcoholic solution is intensely bitter. It unites with the acids to form salts, which crystallize with facility. The neutral gallate, tartrate, and oxalate, like the analogous salts of cinchonia, are insoluble, or nearly so, in cold water. It is unalterable in the air, not even absorbing carbonic acid. Its constituents, according to Pelletier and Dumas, are carbon 75.02, oxygen 10.43, hydrogen 6.66, nitrogen 8.45. Its equivalent number, that of hydrogen being unity, would appear, from the analysis of the sulphate by Pelletier and Caventou, to be 366.47. M. Baup calculates it at 360, and his results accord with the experiments of Winkler and Buchner. (See *Journ. de Pharm.* xvi. 707.) According to Liebig the equivalent is 171.6; but in his view, the sulphate of quinia, instead of being neutral in composition, as considered by the other chemists, consists in fact of two equiv. of base and one of acid. Quinia is obtained by treating its sulphate with the solution of an alkali, collecting the precipitate which forms, washing it till the water comes away tasteless, then drying it, dissolving it in alcohol at 97° F., and slowly evaporating the solution.

The only important artificial salt of quinia is the sulphate, the process for procuring which, as well as its properties, will be hereafter described. (See *Quiniæ Sulphas*, among the Preparations.)

Kinic Acid, and the Kinates of Cinchonia and Quinia. It may be desirable to procure the alkaline principles in that state of saline combination in which they exist in the bark, as it is possible that they may exert an influence over the system in this state, somewhat different from that produced by their combinations with the sulphuric or other mineral acid. As it is impossible to procure the kinates immediately from the bark in a pure state, it becomes necessary first to obtain the kinic acid separately, which may thus become of some practical importance. We shall therefore briefly describe the mode of procuring it, and its characteristic properties. By evaporating the infusion of bark to a solid consistence, and treating the extract thus obtained with alcohol, we have in the residue a viscid matter consisting chiefly of mucilage and kinate of lime.* If an aqueous solution of this substance be formed, and allowed to evaporate at a gentle heat, crystals of the kinate are deposited, which may be purified by a second crystallization. The salt thus obtained, being dissolved in water, is decomposed by means of oxalic acid, which precipitates the lime and leaves the kinic acid in solution. This may be procured in the crystalline state by spontaneous evaporation. The crystals are transparent and colourless, sour to the taste, and readily soluble in alcohol and water. The kinates of cinchonia and quinia may be obtained either by a direct combination of their constituents, or by the mutual decomposition of the sulphates of those alkalies and the kinate of lime. The *kinate of cinchonia* has a bitter and astringent taste, is very soluble in water, is soluble also in alcohol, and is crystallized with difficulty. The *kinate of quinia* is also very soluble in water, but less so in rectified alcohol. Its taste is very bitter, resembling exactly that of yellow bark. It crystallizes in crusts of a mammillated form, and opaque or semitransparent. The salt is with difficulty obtained free from colour, and only by employing the ingredients in a state of extreme purity. (*Ann. de Chim. et de Phys. Juillet* 1829.)

---

* The kinate of lime is soluble in water but not in alcohol.

Of the relations of bark with the several solvents employed in pharmacy we shall speak hereafter, under the heads of its infusion, decoction, and tincture; where we shall also have an opportunity of mentioning some of the more prominent substances which afford precipitates with its liquid preparations. It is sufficient at present to state, that all the substances which precipitate the infusion of bark do not by any means necessarily affect its virtues, as it contains several inert ingredients which form insoluble compounds with bodies which do not disturb its active principles. As gallic, oxalic, and tartaric acids form compounds nearly insoluble in cold water with quinia and cinchonia, it is desirable that substances containing these acids in a free state or in excess, should not be prescribed in connexion with the infusion, decoction, or tincture of bark; for, though it is not improbable that these insoluble gallates, oxalates, and tartrates might be found efficacious if administered, yet being precipitated from the liquid, they would be apt to be thrown away as dregs, or at any rate would communicate to it, if agitated, an unpleasant turbidness.

It is evident from what has been said, that an infusion of bark, on account of the tannin which it contains, may precipitate gelatin, tartar emetic, and the salts of iron, without having a particle of cinchonia or quinia in its composition; and that consequently any inference as to its value drawn from this chemical property, would be altogether fallacious; but, as the active principles are thrown down by gallic acid, no bark can be considered good which does not afford a precipitate with the infusion of galls.

It is impossible to determine with accuracy the relative proportion of the active ingredients in the different varieties of cinchona, as the quantity is by no means uniform in different specimens of the same variety. Pelletier and Caventou state, in their first memoir, that they had been able to obtain only 2 parts of cinchonia from 1000 of pale bark; while from an equal quantity of the yellow they had succeeded in extracting 9 parts of quinia, and from the red 8 parts of cinchonia and 17 parts of quinia. (*Journ. de Pharm.* vii. 92.) But either they employed inferior specimens of the first two varieties, or did not completely exhaust those upon which they experimented. According to a statement subsequently made by them to the French Institute, they obtained from the best Calisaya bark 2.9 per cent. of sulphate of quinia, from inferior kinds 1.5 per cent.; and the average result was 2.33 per cent. (*North Am. Med. and Surg. Journ.* v. 475.) Accounts generally agree in giving less alkaline matter to the pale barks than to the yellow, and more to the red than to either. Mr. Viltmann of Osnabruck, obtained from the Huanuco bark 3.5 per cent. of cinchonia, from the Calisaya or royal yellow, 5 per cent. of quinia, from the red, 6 per cent. of quinia and cinchonia, and from the Carthagena, 3.3 per cent. of alkaline matter. (*Journ. de Chim. Medicale Nov.* 1830.) We cannot, however, avoid suspecting some inaccuracy in the steps by which he obtained results so far exceeding those of the experienced French chemists before quoted.

The following mode of estimating in a hasty way the value of bark by the quantity of alkaline matter it contains, we copy from a communication of M. Tilloy of Dijon, published in the 13th vol. of the *Journ. de Pharmacie*, p. 530. "Take an ounce of the bark coarsely powdered, introduce it into about 12 ounces of alcohol of 30° B. (sp. gr. 0.8748), expose the mixture for half hour to a temperature of from 105° to 120° F., draw off the alcohol, add a fresh portion, and act as before; unite the liquors, and throw into them a sufficient quantity of acetate or subacetate of lead to precipitate the colouring matter and kinic acid, then allow the insoluble matter to subside, and filter. Add to the filtered liquor a few drops of sulphuric acid to separate the excess of acetate of lead, filter, and distil off the alcohol. There remains an acetate or sulphate of quinia, according to the quantity of sulphuric acid employed, together with a fatty matter which will adhere to the vessel. Decant the liquor, and add ammonia, which will instantaneously precipitate the quinia. Too much ammonia will retain it in solution; but in this case a few drops of sulphuric acid will cause it to precipitate. The quinia washed with warm water, and then treated with sulphuric acid, water, and a little animal charcoal, yields very white sulphate of quinia. I have thus obtained in six hours nine grains of the sulphate from an ounce of bark [576 grains French], which is a large proportion when allowances are made for the loss during the process."

Medical Properties and Uses.

This valuable remedy was unknown to the civilized world till about the middle of the seventeenth century; though the natives of Peru are generally supposed to have been long previously acquainted with its febrifuge powers. Humboldt, however, is of a different opinion. In his memoir on the Cinchona forests he states, that it is entirely unknown as a remedy to the Indians inhabiting the country where it grows; and as these people adhere with pertinacity to the practices of their ancestors, he concludes that it never was employed by them. They have generally the most violent prejudices against it, considering it absolutely poisonous; and in the treatment of fever prefer the milder indigenous remedies. Humboldt is disposed to ascribe the discovery of the febrifuge powers of the bark to the Jesuits, who were sent to Peru as missionaries, and among whom were many familiar with the medical knowledge of the day. As bitters had been chiefly relied on in the treatment of intermittent fevers, and as bitterness was observed to be a predominant property in the bark of certain trees which were felled in clearing the forests, the missionaries were naturally led to give it a trial in the same complaint. They accordingly administered an infusion of the bark in the tertian ague, then a prevalent disorder in Peru, and soon ascertained its extraordinary powers. A tradition to this effect is said by Humboldt to be current at Loxa. Ruiz and Pavon, however, are among the writers who ascribe the discovery to the Indians. The Countess of Chinchon, wife of the Viceroy of Peru, having in her own person experienced the beneficial effects of the bark, is said, on her return to Spain in the year 1640, to have first introduced the remedy into Europe. Hence the name of *pulvis Commitissæ*, by which it was first known. After its introduction, it was distributed and sold by the Jesuits, who are said to have obtained for it the enormous sum of its weight in silver. From this circumstance it was called *Jesuits' powder*, a title which it long retained. It had acquired some reputation in England so early as the year 1658; but from its extravagant price, and from the prejudice excited against it, was at first little used. At this early period, however, its origin and nature do not seem to have been generally known; for we are told that Sir John Talbot, an Englishman, having employed it with great success in France, in the treatment of intermittents, under the name of the English powder, at length, in the year 1679, sold the secret of its origin and preparation to Louis XIV., by whom it was divulged.

When taken into the stomach, bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and even vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state. Purging, moreover, is not an unfrequent attendant upon its action. After some time has elapsed, the circulation often experiences its influence, as exhibited in the somewhat increased frequency of pulse; and if the dose be repeated, the whole system becomes more or less affected, and all the functions undergo a moderate degree of excitement. Its action upon the nervous system is sometimes evinced by a sense of tension or fulness or slight pain in the head, singing in the ears, and partial deafness, which are always experienced by some individuals when brought completely under its influence. The effects above mentioned entitle bark to a place among the tonics, and it is usually ranked at the very head of this class of medicines. But besides the mere excitation of the ordinary functions of health, it produces other effects upon the system, which must be considered peculiar, and wholly independent of its mere tonic operation. The power by which, when administered in the intervals between the paroxysms of intermittent disorders, it breaks the chain of morbid association, and interrupts the progress of the disease, is something more than what is usually understood by the tonic property; for no other substance belonging to the class, however powerful or permanent may be the excitement which it produces, exercises a control over intermittents at all comparable to that of the medicine under consideration. As in these complaints it is probable, that in the intervals, a train of morbid actions is going on out of our sight, within the recesses of the nervous system, so it is also probable, that bark produces in the same system an action equally mysterious, which supersedes that of the malady, and thus accomplishes the restoration of the patient. From the possession both of the tonic, and of the *anti-intermittent* property, if we may be allowed so to designate it, bark is capable of being usefully applied in the treatment of a great number of diseases.

It may usually be employed with benefit in all morbid conditions of the system, whatever may be the peculiar modifications, in which a permanent corroborant effect is desirable, provided the stomach be in a proper state for its reception. In low or typhoid forms of disease, in which either no inflammation exists, or that which does exist has been moderated by proper measures, or has passed into the suppurative or the gangrenous stage, this remedy is often of the greatest advantage in supporting the system till the morbid action ceases. Hence its use in the latter stages of typhus gravior; in malignant scarlatina, measles, and small pox; in carbuncle, and gangrenous erysipelas; and in all cases in which the system is exhausted under large purulent discharges, and the tendency of the affection is towards recovery. As a tonic, bark is also advantageously employed in chronic diseases connected with debility; as, for example, in scrofula, dropsy, passive hemorrhages, certain forms of dyspepsia, obstinate cutaneous affections, amenorrhœa, chorea, hysteria; in fact, whenever a corroborant influence is desired, and no contra-indicating symptoms exist. But in all these cases it greatly behooves the physician to examine well the condition of the system, and before resorting to the tonic, to ascertain the real existence of an enfeebled condition of the functions, and the absence of such local irritations or inflammations, especially of the stomach or bowels, as would be likely to be aggravated by its use.

But it is in the cure of intermittent diseases that bark displays its most extraordinary powers. It was originally introduced into notice as a remedy in fever and ague, and the reputation which it acquired at an early period it has ever since retained. Very few cases of this disease will be found to resist the judicious use of bark, or some one of its preparations. This is not the place to speak of the precise circumstances under which it is best administered. It will be sufficient to say, that physicians generally concur in recommending its early employment, in divided doses, to the extent of one or two ounces, during the intermission, and the repetition of this plan till the disease is subdued, or the remedy is found insufficient for its cure. Other intermittent diseases have been found to yield with almost equal certainty to the remedy, particularly those of a neuralgic character. Hemicrania and violent pains in the eye, face, and other parts of the body, occurring periodically, are often almost immediately relieved by the use of bark. Some cases of epilepsy, in which the convulsions recurred at regular intervals, have also been cured by it; and even the hectic intermittent is frequently arrested, though, as the cause still generally continues to operate, the relief is too often only temporary. Diarrhœa and dysentery sometimes put on the intermittent form, especially in miasmatic districts; and under these circumstances may often be cured by bark. Nor is it necessary, that, in the various diseases which have been mentioned, the intermission should always be complete, in order to justify a resort to the remedy. Remittent fevers, in which the remission is very decided, not unfrequently yield to the use of bark, if preceded by proper depleting measures. But, as a general rule, the less of the diseased action there is in the interval, the better is the chance of success; and if it exceed a certain point, the bark has usually been found to aggravate instead of relieving the complaint.

Some observations are requisite as to the choice of the barks and the forms of administration. In the treatment of intermittents, either the red or the yellow bark is decidedly preferable to the pale, and of the first two, the red is usually considered the most powerful. With regard to the red, experience had pronounced in its favour long before analysis had proved its superiority. It not only contains more of the active principles of the bark than the other varieties, but has also the advantage of uniting them both in nearly equal proportion. The pale bark may possibly, in its finest forms, be superior for the purposes of a general tonic, as it is less liable to offend the stomach, and perhaps to irritate the bowels.

Where the object is to make a decided and speedy impression, bark is most effectually administered in substance. We can by no means be absolutely certain that quinia and cinchonia are its only active ingredients; and even supposing them to be so, we are equally uncertain whether they may not be somewhat modified in their properties, even by the therapeutically inert principles with which they are associated. In fact, bark in substance has been repeatedly known to cure intermittents when the sulphate of quinia has failed. It is best administered diffused in water or some aromatic infusion. Experience has proved that its efficacy in the cure of intermittents is often greatly promoted by admixture with other substances. A mixture of powdered bark, Virginia snakeroot, and carbonate of soda, was at one time highly esteemed in this city; and another, consisting of bark, confection of opium, lemon-juice, and port wine, has, in our own experience, and that of some of our friends, proved highly efficacious in some obstinate cases of fever and ague.*

But notwithstanding the superior efficacy of the bark in substance, it is in the great majority of instances sufficient to resort to some one of its preparations; and in many cases we are compelled to this resort by the inability of the stomach to support the powder, or the unwillingness of the patient to encounter its disagreeable taste. The best substitute, in cases of intermittent disease, is decidedly the sulphate of quinia, or sulphate of cinchonia, the former of which is used almost to the exclusion of the latter, though not perhaps upon sufficient grounds. The advantage of these preparations is their great facility of administration, and the possibility, by their employment, of introducing a large quantity of the active matter, with less risk of offending the stomach. The sulphate of quinia is now almost universally employed in the treatment of intermittents, and bark resorted to only after this has failed. (See *Quiniæ Sulphas.*)

Though quinia possesses the anti-intermittent power of bark, it is by no means satisfactorily ascertained that it is capable of exerting all the peculiar influence of that medicine as a tonic; but as bark in powder can seldom be supported by a delicate stomach, for a sufficient period to insure the necessary influence of the medicine in chronic disease, it is customary to resort, in this case, to some one of its preparations in which the quinia is extracted in connexion with the other principles; as the infusion, decoction, tincture, and extract. Each of these will be particularly treated of among the preparations. It is here only necessary to say, that their use is mostly confined to chronic cases; or to those of a malignant character, as typhus gravior, &c., in which the whole virtues of bark are desired, but the stomach is unable to bear the powder. Should bark or its preparations produce purging, as they occasionally do, they should be combined with a small proportion of laudanum.

It is sometimes desirable to introduce bark into the system by other surfaces than that of the stomach; and it has been found to exercise its peculiar influence to whatever part it has been applied. Injected into the rectum, in connexion with opium to prevent purging, it has been employed successfully in the cure of intermittents; and the use of bark jackets, made by quilting the powder between two pieces of flannel or muslin, and worn next the skin, and of bark baths made by infusing the medicine in water, has proved serviceable in cases of children. But the best preparation of bark for external application is decidedly the sulphate of quinia, which, sprinkled upon a blistered surface, denuded of the cuticle, is speedily absorbed, and produces on the system effects not less decided than those which result from its internal administration.

The medium dose of bark, as administered in intermittents, is one drachm, to be repeated more or less frequently according to circumstances. When given as a tonic in chronic complaints, the dose is usually smaller; from ten to thirty grains being sufficient to commence with.

LAURUS. See CAMPHORA.

Laurus Cinnamomum. Willd. *Sp. Plant.* ii. 477; Woodv. *Med. Bot.* p. 670. t. 233.—*Persea Cinnamomum.* Sprengel, *Syst. Veg.* ii. 263.—*Cinnamomum Zeylanicum.* Hayne, *Darstel. und Beschreib.* xii. 20. The cinnamon tree grows to the height of twenty or thirty feet, with a trunk from twelve to eighteen inches in diameter, irregular, knotty, and covered with a thick, rough, scabrous bark, which is externally ash-coloured, internally reddish. The branches are numerous, strong, horizontal, and declining. The young shoots are beautifully speckled with dark green and light orange colours. From the root spring numerous suckers which form a bush about the trunk. The leaves are from six to nine inches long, and from two to three broad, entire, oblong, pointed, three-nerved, with the lateral nerves vanishing as they approach the point. They are in opposite pairs, and stand upon short slightly channeled footstalks. When young they are generally of a scarlet or light liver-colour, become olive as they approach maturity, are afterwards of a shining green, and ultimately, before they fall, of an olive-yellow. The flowers are small, white, and arranged in axillary and terminal panicles. The fruit is an oval berry, which adheres like the acorn to the receptacle, is larger than the black currant, and when ripe has a bluish-brown surface thickly scattered with white spots.

The tree emits no smell perceptible at any distance. The bark of the root has the odour of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odour when rubbed, and a hot taste. The petiole has the flavour of cinnamon. It is a singular fact, that the odour of the flowers is to people in general disagreeable, being compared by some to the scent exhaled from newly sawn bones. The fruit when opened has a terebinthinate odour, and a taste in some degree like that of juniper berries. It is the prepared bark that constitutes the spice so well known and so highly valued under the name of cinnamon.

This species of laurel is a native of Ceylon, where it has long been cultivated for the sake of its bark. It probably grows also in Malabar, in Sumatra, Java, Borneo, Sooloo, and the neighbouring islands; and in Cochin-china, Tonquin, the Chinese province of Quangsi, the Philippines, the Nicobar

Islands, and other parts of the East.* It has at various periods been introduced into the Isle of France, Bourbon, the Cape de Verds, Brazil, Cayenne, several of the West India Islands, and lately into Egypt; and in some of these places is at this time highly productive. This is particularly the case in Cayenne, where the plant was flourishing so early as the year 1755. It has been doubted whether the tree which grows in Sumatra, Cochin-china, &c., is the real Laurus Cinnamomum, or another species of the same genus. Most authors consider it a distinct species, with the name of Laurus Cassia; but there is reason to believe, both from the reports of travellers, and from the similarity of its product with that of the Ceylon tree, that the two plants are specifically identical and differ only in consequence of the variety of soil and climate to which they are exposed.† The Laurus Cinnamomum is exceedingly influenced, as regards the aromatic character of its bark, by the circumstances of soil, climate, and mode of culture. Thus we are told by Marshall that in Ceylon, beyond the limits of Negombo and Matura, in the western and southern aspect of the island, the bark is never of a good quality, being greatly deficient in the spicy, aromatic flavour of the cinnamon; and that even within these limits it is of unequal value from the various influence of exposure, soil, shade, and other circumstances.

Culture, Collection, Commerce, &c. Our remarks under this head will first be directed to the cinnamon of Ceylon, in relation to which we have more precise information than concerning the aromatic obtained from other sources. The bark was originally collected exclusively from the tree in a wild state; but under the government of the Dutch the practice of cultivating it was introduced, and it has been continued since the British have come into possession of the island. The seeds are planted in a prepared soil at certain distances, and as four or five are placed in a spot, the plants usually grow in clusters like the hazel bush. In favourable situations they attain the height of five or six feet in six or seven years, and a healthy bush will then afford two or three shoots fit for peeling; and every second year afterwards will afford from four to seven shoots in a good soil. The cinnamon harvest commences in May and continues till late in October. The first object is to select shoots proper for decortication, and those are seldom cut which are less than half an inch or more than two or three inches in diameter. The bark is divided by longitudinal incisions, of which two are made opposite to each other in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation which facilitates the separation of the cuticle. The epidermis and the green matter beneath it are removed by placing the strip of bark upon a convex piece of wood, and scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, thus forming a congeries of quills into a cylindrical pipe which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about thirty pounds, and deposited in the government warehouses. The East India Company, which has till recently enjoyed a monopoly of the commerce in cinnamon, employed inspectors, who opened the bales and carefully examined every quill, dividing them into three sorts, two of which were intended for exportation, and the third, consisting of bark that was too old, or too young, or altered by the weather, or inferior from some other cause, was rejected. The better kinds were put into bundles, and shipped for England in the Company's vessels at the ports of Galle and Columbo. The bark of inferior quality was either employed for preparing oil of cinnamon, or exported to the continent of India, whence much of it was said to reach Europe under the name of cassia.

---

* Ainslie's Mat. Indic.—Description of the L. Cinnamomum by Marshall. *Electic Repertory*, vol. viii. p. 66. From this last paper we have derived most of the observations which we have made on the cinnamon and cinnamon tree of Ceylon.

† Since the publication of the first edition of this work, we have seen the following notice in the *Lond. and Ed. Philosoph. Mag. for Dec.* 1832, p. 465. In a letter from John B. Batka, an apothecary of Prague, to Mr. Brown, the writer states that, after careful examination, he has concluded that the *L. Cassia* is identical with the *L. Cinnamomum*, the plant commonly cultivated in collections for the L. Cassia, being the *L. Malabathrum*. The species which yields the Chinese cinnamon is not known.

Immense quantities of cinnamon are exported from China, the finest of which is little inferior to that of Ceylon, though the mass of it is much coarser. It passes in commerce under the name of *cassia.* Travellers inform us that the best cinnamon produced in Cochin-china is quite equal to the best of Ceylon; but is monopolized by the sovereign of the country. The inferiority of that which circulates in commerce is probably attributable to the want of care in selecting and preparing the bark. It is supposed that most of the cinnamon obtained from China is imported into that country from Cochin-china and the islands of the Indian Archipelago; but we have good authority for the belief, that this spice is also cultivated within the limits of the Celestial empire.

Cayenne, and several of the West India Islands, yield to commerce considerable quantities of cinnamon of various qualities. That of Cayenne is of two kinds, one of which closely resembles, though it does not quite equal, the aromatic of Ceylon, the other resembles the Chinese. The former is supposed to be derived from plants propagated from a Ceylonese stock, the latter from those which have sprung from a tree introduced from Sumatra.

By far the greater proportion of cinnamon brought to this country is imported from China. It is entered as *cassia* at the custom houses, while the same article brought from other sources is almost uniformly entered as cinnamon. By an examination of the treasury returns from the year 1820 to 1829, we find that the average annual import of this spice has been, in round numbers, 652,000 pounds from China; 12,000 pounds from England, 9,000 pounds from the British East Indies, 3,000 pounds from the West Indies, and an insignificant quantity from all other places, with the exception of 12,758 pounds brought in one year from the Philippines. There is no doubt that much of the amount brought from China is exported; but we have not been able to ascertain the proportion.

Though cassia and cinnamon were both terms used by the ancients, it is impossible to ascertain with certainty whether the spices which they designated were identical with those known by the same names in modern times. Neither the plants nor their localities, as described by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is not improbable that the Arabian or other Eastern navigators, at a very early period, conveyed this spice within the limits of Phœnician and Grecian, and subsequently of Roman commerce.

Properties. *Ceylon cinnamon* is in long cylindrical fasciculi, composed of numerous quills, the larger enclosing the smaller. It is of a light brownish-yellow colour, almost as thin as paper, smooth, shining, pliable to a considerable extent, with a splintery fracture when broken. It has a pleasant fragrant odour, and a warm, aromatic, slightly pungent, sweetish, and highly agreeable taste. When distilled it affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavour. It is brought to this country from England; but is very costly, and is not generally kept in the shops. The finer variety of *Cayenne cinnamon* approaches in character to that just described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young, is scarcely distinguishable from the cinnamon of Ceylon. It is not recognised in our markets as a distinct variety.

The *Chinese cinnamon*, called *cassia* in commercial language, is in single tubes of various sizes, from an eighth of an inch to half an inch or even an inch in diameter. Sometimes the bark is rolled very much upon itself, sometimes is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker colour than the finest of the East India Company's cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and mucilaginous, but less sweet and grateful taste; and, though of a similar odour, is less agreeably fragrant. It is the kind almost universally kept in our shops, and while it is much cheaper than the former variety, is perhaps not inferior to it for the preparation of the various tinctures, &c., into which cinnamon enters as an ingredient. Of a similar character is the cinnamon imported directly from various parts of the East Indies. But under the name of cassia are also brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or injured by want of care in keeping, and perhaps some derived from distinct species of Laurus. It is said, that cinnamon from which the oil has been distilled, is sometimes fraudulently mingled with the genuine. These inferior kinds are detected, independently of their greater thickness, and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice.

We have treated of cinnamon and cassia under the same head; because, even admitting the latter to be sometimes derived from the Laurus Cassia, we are absolutely certain that much of what is sold by that title is real cinnamon, and we are in possession of no grounds by which we can distinguish them. The only differences observable between the numerous varieties, are such as might readily arise from causes unconnected with difference of species; and even the mucilaginous taste of cassia, is ascribed by Dr. A. T. Thomson to the circumstance, that the larger branches being decorticated, and the cuticle only removed, the cellular integument is left, thick, spongy, and full of a slimy mucus. In fact, the very existence of the *Laurus Cassia* as a distinct species, is denied by some botanists, who consider it at most but a variety of the *L. Cinnamomum.*

From the analysis made by Vauquelin, it appears, that cinnamon contains a peculiar essential oil, tannin, mucilage, a colouring matter, an acid, and lignin. The oil obtained from the Cayenne cinnamon, he found to be more biting than that from the Ceylonese, and at the same time to be somewhat peppery. This aromatic yields its virtues wholly to alcohol, and less readily to water. At the temperature of boiling alcohol very little of the oil rises, and an extract prepared from the tincture retains, therefore, the aromatic properties. For an account of the essential oil see *Oleum Cinnamomi.*

Medical Properties and Uses. Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, astringent, and like most other substances of this class, more powerful as a local than general stimulant. It is seldom, however, prescribed alone, though sometimes capable, when given in powder or infusion, of allaying nausea, checking vomiting, and relieving flatulence. It is chiefly used as an adjuvant to other less pleasant medicines, and enters into a great number of officinal preparations. The dose of the powder is from ten grains to a scruple.

Cassia Buds. Under the title of *Flores Lauri Cassiæ*, the Edinburgh College has adopted the *cassia buds* of commerce. They are the dried hexangular receptacles of the seeds of the *Laurus Cinnamomum*, or some analogous species, and are imported exclusively from China. In shape they resemble nails with round heads. The seeds sometimes fall out by drying, and the receptacle is then cup-shaped. They have a brown colour, with the flavour of cinnamon, and yield an essential oil upon distillation. Though little known in this country, they may be used for the same purposes as the bark.

Cocculus. See COLOMBA.

Several species of Cocculus, described by Linnæus under the common title of *Menispermum Cocculus*, but referred to the genus in which they now stand by De Candolle, produce fruit differing only in size, and bearing the same commercial name of *Cocculus Indicus.* The *C. suberosus* and *C. Plukenetii* of Malabar, and the *C. lacunosus* of the Moluccas and Celebes, are particularly designated by authors. The Dublin College recognises only the *C. suberosus*, on the authority of Roxburgh, who raised this plant from genuine seeds which he had received from Malabar, and planted in the recent state. It is a climbing shrub, with a suberose or corky bark; thick, shining, smooth, cordiform leaves, somewhat truncate at the base; and many-flowered panicles.

The fruit of these Cocculi, as found in the shops, is roundish, somewhat kidney-shaped, about as large as a pea; having a thin, dry, blackish, wrinkled exterior coat, within which is a ligneous bivalvular shell, enclosing a whitish, oily, very bitter kernel. *Cocculus Indicus* is without smell, but has an intensely and permanently bitter taste. M. Boullay discovered in the seeds a peculiar bitter principle which he denominated *picrotoxin.* This is white, crystallizable in quadrangular prisms, soluble in twenty-five parts of boiling and fifty of cold water, very soluble in alcohol and ether, but insoluble in the oils. It is poisonous, and in the quantity of from five to ten grains, given to strong dogs, produces death preceded by convulsions. To procure it, the watery extract of the seeds is triturated with pure magnesia, and then treated with heated alcohol, which dissolves the picrotoxin and yields it upon evaporation. In this state, however, it is impure. To obtain it colourless it must be again dissolved in alcohol, and treated with animal charcoal. After filtration and due evaporation, it is deposited in the crystalline form. Besides picrotoxin, Cocculus Indicus contains a large proportion of fixed oil and some other substances of less interest. The active principle above described is said to reside exclusively in the kernel, uponw hich part M. Boullay operated. In the shell, MM. Pelletier and Couerbe have recently discovered two distinct principles, one having alkaline properties and named *menispermin,* (menispermia,) the other identical with it in composition, but differing by its want of alkalinity, by its volatility, and in its solubility and crystalline form, and denominated *paramenispermin.* They have also found, in the same part, a new acid, which they call *hypo-picrotoxic.* The picrotoxin of M. Boullay they believe to possess acid properties, and, under this impression, propose for it the name of *picrotoxic acid.* (*Jour. de Pharm.* xx. 122.)

Medical Poperties, &c. Coccculus Indicus acts upon the system in the manner of the acrid narcotic poisons; but is never given internally. In India it is used to stupefy fishes in order that they may be caught; and it has been applied to the same purpose in Europe and this country. It is asserted that the fish thus taken have no poisonous properties. The powdered seeds, mixed with oil, are employed in the East Indies as a local application in obstinate cutaneous affections. An ointment made with the powder has been usedin tinea capitis and to destroy vermin in the hair. Picrotoxin has been successfully substituted by Dr. Jaeger for the drug itself. Rubbed up with lard in the proportion of ten grains to the ounce, it usually effected cures of tinea capitis in less than a month. W.

COCCUS CACTI. *Ed., Dub.*

Cochineal.

Off. Syn. COCCUS. Coccus cacti, *Lond.*

Cochenille, *Fr., Germ.;* Cocciniglia, *Ital.;* Cochinilla, *Span.*

The Coccus is a genus of hemipterous insects, having the snout or rostrum in the breast, the antennæ filiform, and the posterior part of the abdomen furnished with bristles. The male has two erect wings, the female is wingless. The *C. cacti* is characterized by its depressed, downy, transversely wrinkled body, its purplish abdomen, its short and black legs, and its subulate antennæ, which are about one-third of the length of the body. *Rees's Cyclopædia.*

This insect is found wild in Mexico and the adjoining countries, inhabiting different species of Cactus; and is said to have been discovered also in some of the West India islands, and the southern parts of the United States.

In Mexico, particularly in the provinces of Oaxaca and Guaxaca, it is an important object of culture. The Indians form plantations of a species of Cactus, generally supposed to be the *C. coccinilifer*, but thought by Humboldt to be an undescribed species, upon which the insect feeds and propagates. During the rainy season, a number of the females are preserved under cover upon branches of the plant, and are distributed after the cessation of the rains upon the plants without. They perish very speedily after having deposited their eggs. These, hatched by the heat of the sun, give origin to innumerable minute insects, which spread themselves over the plant. The males, of which, according to Mr. Ellis, the proportion is not greater than one to one hundred or two hundred females, being provided with wings and very active, approach and fecundate the latter. After this period, the females, which before moved about, attach themselves to the leaves, and increase rapidly in size, so that, in the end, their legs, antennæ, and proboscis are scarcely discoverable, and they appear more like excrescences on the plant than distinct animated beings. They are now gathered for use, by detaching them from the plant by means of a blunt knife, a few being left to continue the race. They are destroyed either by dipping them enclosed in a bag into boiling water, or by the heat of a stove. In the former case they are subsequently dried in the sun. The males, which are much smaller than the full grown females, are not collected. It is said that of the wild insect there are six generations every year, furnishing an equal number of crops; but the domestic is collected only three times annually, the propagation being suspended during the rainy season, in consequence of its inability to support the inclemency of the weather.

As kept in the shops, the finer cochineal, *grana fina* of Spanish commerce, is in irregularly circular or oval somewhat angular grains, about one-eighth of an inch in diameter, convex on one side, concave or flat on the other, and marked with several transverse wrinkles. Two varieties of this kind of cochineal are known to the druggists, distinguished by their external appearance. One is of a reddish-gray colour, formed by an intermixture of the dark colour of the insect with the whiteness of a powder by which it is almost covered, and with patches of a rosy tinge irregularly interspersed. From its diversified appearance, it is called by the Spaniards *cochinilla jaspeada.* It is the variety commonly kept in our shops. The other, *cochinilla renegrida*, or *grana nigra*, is dark coloured, almost black, with only a minute quantity of the whitish powder between the wrinkles. The two are distinguished in our markets by the name of *silver grains* and *black grains.* Guibourt supposes the difference to depend upon the effect of culture, or, perhaps, on original varieties in the insect. According to others, it arises from the mode of preparation; the gray cochineal consisting of the insects destroyed by a dry heat; the black, of those destroyed by immersion in hot water, which removes the external whitish powder. There is little or no difference in their quality.

Another and much inferior variety, is the *grana sylvestra* or wild cochineal, consisting partly of very small separate insects, partly of roundish or oval masses, which exhibit, under the microscope, minute and apparently new born insects, enclosed in a white or reddish cotton-like substance. It is scarcely known in our drug market.

Cochineal has a faint heavy odour, and a bitter slightly acidulous taste. Its powder is of a purplish carmine colour, tinging the saliva intensely red. According to Pelletier and Caventou, it consists of a peculiar colouring principle which they call *carmine*, a peculiar animal matter constituting the skeleton of the insect, a fatty matter composed of stearin and elaïn, an odorous fatty acid, and various salts. It was also analyzed by John, who called the colouring principle *cochinilin.* Carmine is of a brilliant purple red colour, unalterable in dry air, fusible at 122° F., very soluble in water, soluble in cold and more so in boiling alcohol, insoluble in ether, and without nitrogen among its constituents. It is obtained by macerating cochineal in ether, and treating the residue with successive portions of boiling alcohol, which on cooling deposite a part of the carmine, and yield the remainder by spontaneous evaporation. It may be freed from a small proportion of fatty matter which adheres to it, by dissolving it in alcohol of 40° Baumé, and then adding an equal quantity of sulphuric ether. Pure carmine is deposited in the course of a few days. The watery infusion of cochineal is of a violet crimson colour, which is brightened by the acids, and deepened by the alkalies. The colouring matter of cochineal is readily precipitated. The salts of zinc, bismuth, and nickel, produce a lilac precipitate, and those of iron a dark purple approaching to black. The salts of tin, especially the nitrate and muriate, precipitate the colouring matter of a brilliant scarlet, and form the basis of those splendid scarlet and crimson dyes, which have rendered cochineal so valuable in the arts. With alumina the colouring matter forms the pigment called *lake.* The finest *lakes* are obtained by mixing the decoction of cochineal with freshly prepared gelatinous alumina. The pigment called *carmine* is the colouring matter of cochineal precipitated from the decoction by acids, the salts of tin, &c., or animal gelatin, and when properly made is of the most intense and brilliant scarlet.

Medical Properties, &c. Cochineal is supposed by some to possess anodyne properties, and has been recommended in hooping cough and neuralgic affections; but it is little used internally. In pharmacy it is employed to colour tinctures and ointments.

The dose of a tincture prepared by macerating one part of cochineal in eight parts of diluted alcohol, is for an adult from twenty to thirty drops twice a day. In neuralgic paroxysms, Sauter gave half a tablespoonful, with the effect of curing the disease. W.

* * *

COCHLEARIA OFFICINALIS. Herba. *Dub.*

Common Scurvy-grass.

Cranson, Herbe aux cuillers, *Fr.;* Löffelkraut, *Germ.;* Coclearia, *Ital., Span.*

Cochlearia. See ARMORACIA.

Cochlearia officinalis. Willd. *Sp. Plant.* iii. 448; Woodv. *Med. Bot.* p. 393. t. 112. The common scurvy-grass is an annual or biennial plant, sending up early in the spring a tuft of radical leaves, which are heart-shaped, roundish, of a deep shining green colour, and supported on long footstalks. The leaves of the stem are alternate, oblong, somewhat sinuate, the lower petiolate, the upper sessile. The stem is erect, branched, angular, six or eight inches high, and bears at the extremity of the branches, numerous white cruciform peduncled flowers, in thick clusters. The fruit is a roundish two-celled pod, containing numerous seeds. The whole plant is smooth and succulent.

It is a native of the northern countries of Europe, where, as well as in the United States, it is occasionally cultivated in gardens. The whole herb is officinal. It has, when fresh, a pungent unpleasant odour if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil which is separable in very small quantity by distillation with water.

Medical Properties and Uses. Common scurvy-grass is gently stimulant, aperient, and diuretic. It is highly celebrated as a remedy in sea scurvy; and has been recommended in chronic obstructions of the viscera, and certain forms of chronic rheumatism. The fresh plant may be eaten as a salad, or used in the form of infusion in water or wine, or of the expressed juice. Alcohol and water are impregnated with its virtues by distillation, and the distilled spirit has been found useful in paralysis in the dose of thirty drops several times a day. The expressed juice may be used as a local application in scorbutic affections of the gums. W.

Gen. Ch. A *spathe. Corolla* six-parted, with a tube proceeding directly from the root. *Capsules* three, connected, inflated. *Willd.*

Colchicum autumnale. Willd. *Sp. Plant.* ii. 272; Woodv. *Med. Bot.* p. 759. t. 258. The meadow-saffron is a perennial bulbous plant, the leaves of which appear in spring, and the flowers in autumn. Its manner of growth is peculiar, and deserves notice in this place, as connected in some measure with its medicinal efficacy. In the latter part of summer a new bulb begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom, and embraces it half round. The new plant sends out fibres from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a purplish rosy colour, emerge from the spathe, unaccompanied with leaves. The corolla consists of a tube five inches long concealed for two-thirds of its length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground till the following spring, when they rise upon a stem above the surface in the form of a three-lobed, three-celled capsule. The leaves of the new plant appear at the same time, so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about five inches long, and one inch broad at the base. In the mean time, the new bulb has been increasing at the expense of the old, which having performed its appointed office perishes, while the former, after attaining its full growth, sends forth new shoots from itself, and in its turn decays. Each parent bulb has two offsets.

The C. autumnale is a native of the temperate parts of Europe, where it grows wild in moist meadows. Various attempts have been made to introduce its culture into this country, but with no very encouraging success; though small quantities of the bulb of apparently good quality have been brought into the market. The officinal portions are the bulb and seed. The root, botanically speaking, consists of the fibres which are attached to the base of the bulb. The Pharmacopœias, in adopting the term *Colchici Radix* as officinal, are justified by common usage; while those of the United States and Dublin take care to secure the reader against the possibility of error by designating the bulb as the part intended. The flowers have been found to possess similar virtues with the bulb and seeds, but have not been adopted in the Pharmacopœias.

1. Colchici Radix.

The medicinal virtue of the bulb depends much upon the season at which it is collected. Early in the spring it is too young to have fully developed its peculiar properties; and late in the fall it has become exhausted by the nourishment which it has afforded to the new bulb. The proper period for its collection is from the early part of June, when it has usually attained perfection, to the middle of August, when the offset appears. It is probably owing, in great measure, to this inequality in the colchicum at different seasons, that entirely opposite reports have been given by different authors of its powers. Krapf ate whole bulbs without experiencing inconvenience; Haller found it entirely void of taste and acrimony; and we are told that in Carniola the peasants use it as food with impunity in the autumn. On the contrary, abundant testimony might be adduced of its highly irritating and poisonous nature, of which in fact there exists at present no doubt. Perhaps soil and climate may have some influence in modifying its character.

The meadow-saffron bulb is often used in the fresh state in the countries where it grows, as it is apt to be injured in drying, unless the process is very carefully conducted. The usual plan is to cut the bulb, as soon after it has been dug up as possible, into thin transverse slices, which are spread out separately upon paper or perforated trays, and dried with a moderate heat. The reason for drying it very speedily after removal from the ground, is that it otherwise begins to vegetate, and a change in its chemical nature takes place; and such is its retentiveness of life, that if not cut in slices, it is liable to undergo a partial vegetation even during the drying process. It sustains much loss of weight by exsiccation. Mr. Bainbridge obtained only two pounds fifteen ounces of dried bulb from eight pounds of the fresh.

Properties. The recent bulb of the C. *Autumnale* resembles that of the tulip in shape and size, and is covered with a brown membranous coat. Internally it is solid, white and fleshy; and when cut transversely, yields, if mature, an acrid milky juice. Professor Coxe lays much stress on a small lateral projection from its base, which serves in his opinion to distinguish it from all other bulbs; but which appears to be merely a connecting process between it and the new plant, and is not always present. When dried and deprived of its external membranous covering, the bulb is of an ash-brown colour, convex on one side, and marked on the other by a deep groove extending from the base to the summit. As found in our shops it is always in the dried state, sometimes in segments made by vertical sections of the bulb, but generally in transverse circular slices, about the eighth or tenth of an inch in thickness, with a notch at one part of their circumference.

The cut surface is white, and of an amylaceous aspect. The odour of the recent bulb is said to be *hircine;* the dried is inodorous. The taste is bitter, hot, and acrid. Its constituents, according to Pelletier and Caventou, are a peculiar vegetable alkali denominated *veratria*,* combined with an excess of gallic acid; a fatty matter composed of elaïn, stearin, and a peculiar volatile acid analogous to the cevadic; a yellow colouring matter; gum; starch; inulin in large quantity; and lignin. The active properties are ascribed to the *veratria*, for an account of which see *Veratrum album.* Wine and vinegar extract all the virtues of the bulb. Dr. A. Thomson informs us that the milky juice of fresh colchicum produces a beautiful cerulean blue colour, if rubbed with the alcoholic solution of guaiac; and that the same effect is obtained by substituting for the juice an acetic solution of the dried bulb. He considers the appearance of this colour, when the slices are rubbed with a little distilled vinegar and tincture of guaiac, as a proof that the drug is good and has been well dried. A very deep or large notch in the circumference of the slices is considered by the same author an unfavorable sign, as it indicates that the bulb had been somewhat exhausted in the nourishment of the offset.

Medical Properties and Uses. Meadow-saffron acts upon the nervous system, allaying pain and producing other sedative effects, even when it exerts no obvious influence over the secretions. Generally speaking, when taken in doses sufficiently large to affect the system, it gives rise to more or less disorder of the stomach or bowels, and sometimes occasions active vomiting and purging, with the most distressing nausea. When not carried off by the bowels, it often produces copious diaphoresis, and occasionally acts as a diuretic and expectorant; and a case is on record of violent salivation supposed to have resulted from its use. (*N. Am. Med. and Surg. Jour.* x. 204.) It appears in fact to have the property of stimulating all the secretions, while it rather diminishes than otherwise the action of the heart. In an overdose it is capable of producing dangerous and even fatal effects. It was well known to the ancients as a poison, and is said to have been employed by them as a remedy in gout and other diseases. Störck revived its use among the moderns. He gave it as a diuretic and expectorant in dropsy and humoral asthma; and on the continent of Europe it acquired considerable reputation in these complaints; but the uncertainty of its operation led to its general abandonment, and it had fallen into almost entire neglect, when Dr. Want of London again brought it into notice, by attempting to prove its identity with the active ingredient of the *eau medicinale d'Husson*, so highly celebrated as a cure for gout. The white hellebore had also been considered by some physicians the chief constituent of this empyrical remedy; and the discovery of *veratria* both in the Colchicum and Veratrum album, is an evidence as well of the sagacity of those who traced the resemblance between the actions of these medicines, as of the existence of this alkaline principle in the *eau medicinale*. The chief employment of the meadow-saffron is at present in the treatment of gout and rheumatism, in which experience has abundantly proved it to be a highly valuable remedy. We have, within our own observation, found it especially useful in these affections, when of a neuralgic character. It sometimes produces relief without obviously affecting the system; but is more efficient when it evinces its influence upon the skin or alimentary canal. Professor Chelius states that it changes the chemical constitution of the urine in arthritic patients, producing an evident increase of the uric acid. (*N. Am. Med. and Surg. Jour.* xi. 234.) Dr. Elliotson successfully treated a case of prurigo with the wine of meadow-saffron given in the dose of half a drachm three times a day, and continued for three weeks. (*Medico-Chirug. Rev. Oct.* 1827.) Mr. Ritton has found the powdered bulb an effectual remedy in numerous cases of leucorrhœa. (*Am. Jour. of the Med. Sci.* xv. 527.) The medicine is generally given in the state of vinous tincture. (See *Vinum Colchici Radicis.*) The dose of the dried bulb is from two to eight grains, which may be repeated every four or six hours till the effects of the medicine are obtained.

---

* According to Geiger and Hesse, whose experiments have but recently been made known in this country, the organic alkali of the meadow-saffron is peculiar, and entirely distinct from veratria, with which it has been confounded. It has a very bitter and sharp taste, but is destitute of the extreme acrimony of veratria, and does not, like this principle, excite violent sneezing when applied to the nostrils. It differs also in being more soluble in water, and less poisonous in its influence on the animal system. To a kitten eight weeks old, one-tenth of a grain was given dissolved in a little dilute alcohol. Violent purging and vomiting were produced, with apparently severe pain and convulsions, and the animal died at the end of twelve hours. The stomach and bowels were found violently inflamed, with effusion of blood throughout their whole extent. A kitten somewhat younger was destroyed in ten minutes by only the twentieth of a grain of veratria; and on examination after death, marks of inflammation were found only in the upper part of the œsophagus. We do not know that the conclusions of Geiger and Hesse have yet been confirmed by other experimentalists.—(*See Journ. of Phil. Col. of Pharm.* vi. 320.

2. Colchici Semen.

The seeds of the meadow-saffron ripen in summer, and should be collected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil, or in confined gardens. (*Williams.*) They are nearly spherical, about the eighth of an inch in diameter, and of a reddish-brown colour externally. Their active properties reside in the testa or husk, and they should not, therefore, be bruised in the preparation of the wine or tincture.* Dr. Williams of Ipswich in England, who first brought them into notice, recommends them in the warmest terms in chronic rheumatism, and considers them superior to the bulb, both in the certainty of their effects and the mildness of their operation. There is no doubt that they possess virtues analogous to those of the bulb, and have this advantage, that they are not liable to become injured by drying—an advantage of peculiar value in a country where the plant is not cultivated, and where the bulb cannot be readily procured in the fresh state. A wine of the seeds is directed in the United States Pharmacopœia. Their dose is about the same with that of the bulb.

---

* The following description of the seeds is given by Mr. Gray in the Lond. Med. Repository for April, 1821. "*Seeds*, ovate, globose, about one-eighth of an inch in diameter. *Integuments*, simple, soft, spongy, membranaceous, thin, reddish-brown, closely adherent to the perisperm. *Perisperm* or *albumen*, hard, rather cartilaginous, pellucid, pale, not in the least divided, of the same shape as the seed. *Corculum* or *embryo*, very small, ovate globose, not in the least divided, whitish, placed nearly opposite to the *hylum*, or that part where the seed is affixed to the parent plant, but out of the axis of the seed. Base pointing to the hylum, slender. Apex very obtuse." An acquaintance with the real characters of the seeds is the more necessary, as the seeds of other plants have been sold for them.

Cucumis Colocynthis. Willd. *Sp. Plant.* iv. 611; Woodv. *Med. Bot.* p. 189. t. 71. The *bitter cucumber* is an annual plant, bearing considerable resemblance in appearance to the common cucumber of our gardens. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighbouring bodies to which they attach themselves by their numerous tendrils. The leaves are of a triangular shape, many-cleft, variously sinuated, obtuse, hairy, of a fine green colour on the upper surface, rough and pale on the under; and stand alternately upon long petioles. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular berry or pepo, of the size of a small orange, yellow and smooth when ripe; and contains, within a hard coriaceous rind, a white, spongy, medullary matter, enclosing numerous ovate, compressed white seeds.

The plant is a native of Turkey, and abounds in the islands of the Archipelago. It grows also in various parts of Africa and Asia. Burkhardt, in his travels across Nubia, found the country covered with it; Thunberg met with it at the Cape of Good Hope; and Ainslie says that it grows in many parts of Lower India, particularly in sandy situations near the sea.

The fruit is gathered in autumn, when it begins to assume a yellow colour, and having been peeled, is dried quickly, either in a stove or by the sun. Thus prepared it is imported from the Levant.

Properties. As kept in the shops, colocynth is in the shape of whitish balls, about the size of a small orange, very light and spongy, and abounding in seeds which constitute three-fourths of their whole weight. The seeds are destitute of active properties, and are even employed as food in some parts of Northern Africa. When the medicine is prepared for use, they are separated and rejected, the pulpy or medullary matter only being employed. This has a very feeble odour, but a nauseous and intensely bitter taste. Vauquelin obtained the bitter principle in a separate state, and called it *colocynthin.* According to the analysis of Meissner, 100 parts of the dry pulp of colocynth contain 14.4 parts of colocynthin, 10.0 of extractive, 4.2 of fixed oil, 13.2 of a resinous substance insoluble in ether, 9.5 of gum, 3.0 of pectic acid (pectin), 17.6 of gummy extract derived from the lignin by means of potassa, 2.7 of phosphate of lime, 3.0 of phosphate of magnesia, and 19.0 of lignin, besides water. (*Berzelius, Trait. de Chim.*) Colocynthin is obtained by boiling the pulp in water, evaporating the decoction, treating the extract thus procured with alcohol, evaporating the alcoholic solution, and submitting the residue, which consists of the bitter principle and acetate of potassa, to the action of a little cold water, which dissolves the latter, and leaves the greater part of the former untouched. It is of a yellowish-brown colour, somewhat translucent, brittle and friable, inflammable, more soluble in alcohol than in water, but capable of imparting to the latter an intense bitterness. The aqueous solution gives with the infusion of galls an abundant white precipitate. An infusion of colocynth, made with boiling water, has a golden-yellow colour, and gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and afterwards with water, 168 parts of alcoholic and 216 of aqueous extract.

Medical Properties and Uses. The pulp of colocynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and sometimes bloody discharges, with dangerous inflammation of the bowels. Even in moderate doses it sometimes acts with much harshness, and is therefore seldom prescribed alone. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used, especially by the German practitioners, in obstinate cases of dropsy, and various affections depending on disordered action in the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy; and in this state is very extensively employed. The compound extract of colocynth is a favourite preparation with many practitioners; and combined with calomel, extract of jalap, and gamboge, it forms a highly efficient and safe cathartic, especially applicable in congestion of the portal circle, and torpidity of the liver. (See *Pilulæ Catharticæ Compositæ.*) The dose of colocynth is from five to ten grains. It is best administered in a state of minute division effected by trituration with gum or farinaceous matter.

Thunberg states that the fruit of the C. Colocynthis, at the Cape of Good Hope, is rendered so mild by being properly pickled, that it is eaten both by the natives and colonists; but as it is thus employed before attaining perfect maturity, it is possible that the drastic principle may not have been developed.

Off. Syn. CALUMBA. Cocculus palmatus. Radix. *Lond.;* COLOMBÆ RADIX. *Ed.;* COLOMBA. Radix. *Dub.*

Colombo, *Fr.;* Columbowurzel, *Germ.;* Columba, *Ital.;* Raiz de Columbo, *Span.;* Kalumbo, *Port.;* Calumb, *Mozambique.*

The colombo plant was until a recent period unknown to botanists. In the year 1805, M. Fortin, a French gentleman resident at Madras, took to that city from Mozambique an offset from the root, from which a plant was raised in the garden of Dr. Anderson. From a drawing made of this plant, it was ascertained to belong to the natural order *Menispermeæ;* but as the female flowers were wanting, some difficulty was experienced in determining the genus and species. It has, however, been placed in the genus *Cocculus* of De Candolle, separated by that botanist from the genus *Menispermum*, and including those species which have six stamens, while the Menispermum is limited to those with twelve or more. In the Pharmacopœias of the United States and London, the plant is recognised as the *Cocculus palmatus.*

COCCULUS. *Sex. Syst.* Diœcia Dodecandria.—*Nat. Ord.* Menispermeæ.

Gen. Ch. Sepals and Petals ternate, usually in two, rarely in three rows. MALE. *Stamens* six, distinct, opposite the petals. FEMALE. *Drupes* berried, 1–6, generally oblique, reniform, somewhat compressed, one-seeded. *Cotyledons* distinct. *Loudon's Encyc.*

Cocculus palmatus. De Cand. *Syst. Nat.* i. 515; Berry, *Asiat. Research.* x. 385.—*Menispermum palmatum.* Willd. *Sp. Plant.* iv. 825. This is a climbing plant, with a perennial branching root, and annual stems, which are simple, twining, round, hairy, and of the thickness of a goose-quill. The leaves, which stand on round hairy petioles, are alternate, distant, palmate, with five entire acuminate lobes, and five nerves, each of which runs to one of the lobes. The flowers are small, and in axillary solitary compound racemes shorter than the leaves. The calyx has six leaflets, three of which are exterior, three interior; and the corolla has the same number of petals. There are six stamens, which are rather longer than the corolla. The male plant only has been described.

This species of Cocculus is a native of Mozambique, on the south-eastern coast of Africa, where it grows wild in great abundance in the thick forests which extend from the sea many miles into the interior. The plant is never cultivated. The root is dug up in March, when dry weather prevails. From the base of the root numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into transverse slices, which are dried in the shade. The old root is rejected.

Columbo is a staple export of the Portuguese from their dominions in the South East of Africa. It is taken to India, and thence distributed to various parts of the world. It was formerly supposed to be a product of Ceylon, and to have derived its name from Colombo, a city of that island, from which it was thought to be exported. It is possible that, when the Portuguese were in possession of Ceylon, Colombo may have been the entrepot for the drug brought from Africa, and thus have given origin to its name; but a more probable derivation appears to be from the word *calumb*, which is said to be the Mozambique name for the root.

Properties. The root, as it reaches us, is in flat circular or oval pieces, from the eighth of an inch to near an inch in thickness, and from one to two inches in diameter. The cortical portion is thick, of a bright yellow slightly greenish colour internally, but covered with a brownish wrinkled cuticle. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the centre; and is frequently marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest colour, are most compact and uniform in their texture, and are most free from the worm-holes by which the root is apt to be penetrated. The odour of colombo is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is brittle, and easily pulverized. The powder has a greenish tinge, which becomes browner with age and deepens when it is moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities at a time.

M. Planche analyzed columbo in 1811, and found it to contain a peculiar azotized substance in large quantity, a bitter yellow substance not precipitated by metallic salts, and one-third of its weight of starch. He obtained also a small proportion of essential oil, salts of lime and potassa, oxide of iron, and silica. Mr. Wittstock of Berlin has subsequently isolated a peculiar crystallizable principle, in which the bitterness resides, and for which he proposes the name of *colombin.* (*Journ. de Pharm. Fevrier*, 1831.) It appears to be the bitter yellow substance of Planche, deprived of a portion of colouring matter. *Colombin* crystallizes in beautiful transparent quadrilateral prisms, is without smell, and is extremely bitter. It is but very slightly soluble in water, alcohol, or ether, at ordinary temperatures, and yet imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is diluted acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It has neither acid nor alkaline properties, and its alcoholic and acetic solutions are not affected by the metallic salts, nor the infusion of galls. The process for obtaining it consists in exhausting columbo by means of alcohol of the sp. gr. 0.835, distilling off three-quarters of the alcohol, allowing the residue to stand for some days till crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother-waters still contain a considerable quantity of colombin, which may be separated by evaporating with coarsely powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution so that crystals may form. Colombin is thought to be the active principle of columbo, but is probably somewhat modified in its action on the system by the other substances with which it is associated. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by the infusion of galls, the acetate and subacetate of lead, corrosive chloride of mercury, and lime-water; but the bitter principle is not affected by these reagents.

Adulterations. In France, a spurious columbo has been extensively substituted for the genuine root, which, according to Guibourt, has become rare in the commerce of that country. As it may possibly be introduced into our market, it is desirable that our druggists should be put in possession of the characters by which it may be distinguished. Though similar to columbo in appearance, it is different in properties, and is therefore truly a sophistication. It is said to be taken to France from Barbary; but the plant which yields it is not known. Though in round slices like the genuine root, it has an epidermis of a gray-fawn colour, marked with close and parallel circular striæ; its transverse surfaces are irregularly depressed; the medullary portion is of a yellowish-orange, with a deeper coloured circle; the smell is weak like that of gentian, the taste feebly bitter and rather saccharine; the powder is of a yellow-fawn instead of a greenish colour; but the most striking difference is the total absence of starch, which constitutes one-third of columbo. Iodine therefore is an excellent test. If the true columbo be moistened with hot water, and touched with iodine, it immediately assumes a blackish colour; while the spurious root, treated in the same way, undergoes no change. The latter differs also in communicating a fine yellow colour to ether, in evolving ammonia when treated with caustic potassa, and in reddening in infusion the tincture of litmus.

It is said that the root of white bryony, tinged yellow with the tincture of columbo, has sometimes been fraudulently substituted; but the adulteration is too gross to deceive those acquainted with the characters of either of these drugs.

The American columbo, the root of the *Frasera Walteri*, is said to be sold in some parts of Europe for the genuine. Independently of the sensible differences between the two roots, (see *Frasera*,) M. Stolze of Halle states, that while the tincture of columbo remains unaffected by the protosulphate or permuriate of iron, and gives a dirty gray precipitate with tincture of galls, the tincture of frasera acquires a dark green with the former reagent, and is not affected by the latter. (*Duncan.*)

Medical Properties and Uses. Columbo is among the most useful of the mild tonics. Without astringency, with very little stimulating power, and generally acceptable to the stomach, it answers admirably as a remedy in simple dyspepsia, and in those states of debility which are apt to attend convalescence from acute disorders, especially when the alimentary canal is left in an enfeebled condition. Hence it is often prescribed in the declining stages of remittent fever, dysentery, diarrhœa, cholera morbus, and cholera infantum. The absence of irritating properties renders it also an appropriate tonic in the hectic fever of phthisis, and its kindred affections. It is frequently administered in combination with other tonics, with aromatics, with mild cathartics, and with antacids. The remedy which we have found most effectual in the permanent cure of a disposition to the accumulation of flatus in the bowels, is an infusion made with half an ounce of columbo, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in the dose of a wineglassful three times a day. Columbo is much used by the natives of Mozambique, and the neighbouring parts of Africa, in dysentery and other diseases. (*Berry.*) It was first introduced to the notice of the profession in Europe by Francois Redi, in the year 1685.

It is most commonly prescribed in the state of infusion. (See *Infusum Colombæ.*) The dose of the powder is from ten to thirty grains, and may be repeated three or four times a day. It is frequently combined with powdered ginger, carbonate of iron, and rhubarb.

CONIUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Partial Involucre* halved, usually three-leaved. *Fruit* nearly globular, five-streaked, notched on both sides. *Willd.*

Conium maculatum. Willd. *Sp. Plant.* i. 1395; Bigelow, *Am. Med. Bot.* i. 113; Woodv. *Med. Bot.* p. 104. t. 42. This is an umbelliferous plant, having a biennial spindle-shaped whitish root, and an herbaceous branching stem, from three to six feet high, round, hollow, smooth, shining, slightly striated, and marked with brownish-purple spots. The lower leaves are tripinnate, more than a foot in length, shining, and attached to the joints of the stem by sheathing petioles; the upper are smaller, bipinnate, and inserted at the divisions of the branches; both have channeled footstalks, and incised leaflets which are deep green on their upper surface and paler beneath. The flowers are very small, white, and disposed in compound terminal umbels. The general involucre consists of from five to seven lanceolate, reflected leaflets, whitish at their edges; the partial involucre, of three or four, oval, pointed, spreading, and on one side only. The petals are cordate, with their points inflected, five in number, and nearly equal. The stamens are spreading, and about as long as the corolla; the styles diverging. The fruit is roundish ovate, striated, and composed of two plano-convex seeds, which have on their outer surface five crenated ribs.

The hemlock is a native of Europe, and has been introduced into the United States, where it is now naturalized. It grows usually in bunches along the road sides or in waste grounds, and is found most abundantly in the neighbourhood of old settlements. Its flowers appear in June and July. The whole plant, especially at this period, exhales a fetid odour, usually compared to that of the urine of cats; and narcotic effects are experienced by those who breathe for a long time air impregnated with the effluvia. The plant varies in narcotic power according to the climate and character of the weather, being most active in hot and dry seasons, and in warm countries. The hemlock of Greece, Italy, and Spain, is said to be much more energetic than that of the North of Europe. As a general rule, those plants are most active which grow in a sunny exposure. The proper season for gathering the leaves is when the plant is in flower; and Dr. Fothergill asserts from experimental knowledge, that they are most active about the time when the flowers begin to fade. The footstalks should be rejected, and the leaflets quickly dried, either in the hot sun, or on tin plates before a fire. They should be kept in boxes or tin cases excluded as much as possible from the air and light, by exposure to which they lose their fine green colour, and become deteriorated in medical virtues. The same end is answered by pulverizing them, and preserving the powder in opaque and well stopped bottles.

The term *cicuta*, which till recently was very often applied to this plant, belongs to a different genus.

Properties. The dried leaves of the hemlock have a strong, heavy, narcotic odour, less disagreeable than that of the recent plant. Their taste is bitterish and nauseous; their colour a fine green, which is retained in the powder. The acrimony of the fresh leaves is dissipated by drying, leaving the narcotic property unimpaired. Water distilled from them has the odour of hemlock and a very nauseous taste, but does not produce narcotic effects upon the system. The decoction has little taste, and the extract resulting from its evaporation is nearly inert. From these facts it is inferrible that the active principle, as it exists in the plant, is not volatile at 212°, and is little soluble in water. Alcohol and ether, however, take up the narcotic properties of the leaves; and the ethereal extract, which is of a rich dark green colour, is stated by Dr. A. T. Thomson to have the smell and taste of the plant in perfection, and in the dose of half a grain to produce headach and vertigo. Dr. Paris has prematurely proposed for this substance the name of *conein*, as it has no claim to be considered the active principle, which is only one of its ingredients. We have no satisfactory analysis of hemlock. Schrader found in the juice of the leaves, resin, extractive, gum, albumen, a green fecula, and various saline substances. Brandes obtained from the plant a very odorous oil, albumen, resin, colouring matter, salts, and a peculiar alkaline principle of a strong narcotic smell, a disagreeable nauseous taste insoluble in water, and in the quantity of half a grain producing vertigo a intense headach. This principle has been variously called *cicutin*, *coniin*, and *conicine;* but the most appropriate name would be *conia*. It is obtained by digesting the bruised leaves and stem, for several days, in alcohol, filtering and evaporating the tincture, treating the alcoholic extract with water, adding magnesia, or hydrate of alumina, evaporating the whole to dryness, and submitting the residue to the action of a mixture of ether and alcohol. The solution thus obtained, when filtered and evaporated, yields the principle in question, in the form of a light brownish-yellow substance having the appearance of an extract. It is hardly probable that the *conia* thus obtained is perfectly pure. From recent experiments of Geiger it appears, that the alkaline principle of hemlock is volatile in the uncombined state. He procures it by distilling fresh hemlock with caustic potassa and water, neutralizing the product with sulphuric acid, evaporating to the consistence of syrup, adding anhydrous alcohol so long as a precipitate of sulphate of ammonia is afforded, separating this salt from the liquor, distilling off the alcohol, mixing the residue with a strong solution of caustic potassa, and distilling anew. The *conia* passes over with the water, from which it separates in the form of a yellowish oil, of a strong odour resembling at the same time that of hemlock and tobacco, and an extremely acrid and bitter taste. It is soluble in water, and has a strong alkaline reaction, combining with and neutralizing the acids, and even fuming in some measure like ammonia, on the approach of the volatile acids. It is very poisonous, as are also its salts, though in a much less degree. (*Berzelius*, *Trait. de Chim.*) Some experiments recently made by M. Deschamps have led him to the conclusion, that the volatile substance obtained by Geiger owed its alkalinity to the presence of ammonia. These experiments, however, are not considered as entirely satisfactory by MM. Planche and Boutron, to whom the subject wasreferred by the Society of Pharmacy of Paris. (*See Journ. de Pharm.* xxi. 77 and 84.)

Medical Properties and Uses. Hemlock is narcotic, without being decidedly stimulant or sedative. When given so as fully to affect the system, it produces more or less vertigo, dimness of vision, nausea, faintness, and general muscular debility. In larger doses it occasions dilated pupils, difficulty of speech, delirium or stupor, tremors and paralysis, and ultimately convulsions, and even death. Its operation usually commences in less than half an hour, and if moderate seldom continues longer than twenty-four hours. It is supposed to be the narcotic used by the Athenians to destroy the life of condemned individuals, and by which Socrates and Phocion died. It was also used by the ancients as a medicine, but fell into entire neglect; and was not again brought into notice till the time of Störck, by whom it was much employed and extravagantly praised. Since that period it has been submitted to ample trial, and though its original reputation has not been fully sustained, it still retains a place in the catalogue of useful medicines. It was highly recommended by Störck as a remedy in scirrhus and cancerous ulcers; but at present is considered only a useful palliative in this complaint. In chronic enlargements of the liver and other abdominal viscera; in painful scrofulous tumours and ulcers; in various diseases of the skin, as leprosy and elephantiasis; in the complicated derangements of health attendant upon secondary syphilis; in chronic rheumatism and neuralgic affections; in pertussis, asthma, chronic catarrh, and consumption; and in various other disorders connected with nervous derangement, or a general depraved state of the health, it is occasionally employed with the effect of relieving or palliating the symptoms, or favourably modifying the action of remedies with which it is combined. Dr. Gibson, professor of Surgery in the University of Pennsylvania, speaks highly of its efficacy in the cure of goitre. (See *Phil. Journ. of the Med. and Phys. Scien.* i. 67.)

The powdered leaves, and the inspissated juice (the extract of the Pharmacopœias), are the forms in which it is usually administered. Either of these may be given in the dose of three or four grains twice a day, gradually increased till the occurrence of slight vertigo or nausea indicates that it has taken effect. To maintain a given impression, it is necessary to increase the dose even more rapidly than is customary with most other narcotics, as the system becomes very speedily habituated to its influence. In some instances, the quantity administered in one day has been augmented to more than two ounces. The strength of the preparations of hemlock is exceedingly unequal; and caution is therefore necessary, when the medicine is given in very large quantities, to employ the same parcel, or, if a change be made, to commence with the new parcel in smaller doses, so as to obviate any danger which might result from its greater power. Unpleasant consequences have resulted from a neglect of this precaution. A tincture of hemlock is directed by the Edinburgh and Dublin Colleges, and is an efficient preparation. The fresh juice of the plant has been recommended by Hufeland in the dose of from twelve to forty drops. The seeds have also been employed, and Cullen states that an extract prepared from them is stronger than that of the plant. The fresh leaves are sometimes used externally as an anodyne cataplasm.

Though fatal to some animals, hemlock is eaten with impunity by others, as horses, goats, and sheep. The best method of relieving its poisonous effects, is the speedy evacuation of the stomach.

Gen. Ch. Receptacle common, one-leafed, fleshy, in which solitary *seeds* are nestled. *Willd.*

The root known by the name of *contrayerva* is believed to be derived from several species of Dorstenia, among which, besides the *D. Contrayerva,* two others are mentioned by Dr. Houston, the *D. Houstonia,* and *D. Drakena* of Willdenow. The first only is recognised in the Pharmacopœias of the United States and Great Britain.

Dorstenia Contrayerva. Willd. *Sp. Plant.* i. 682; Woodv. *Med. Bot.* p. 705. t. 240. This plant has a perennial, fusiform, branching, rough, compact root, which sends up several leaves of an irregular shape, about four inches in length, lobed, serrated, pointed, and placed upon long radical footstalks, which are winged towards the leaves. The scapes or flower-stems are also radical, rise several inches in height, and support irregular quadrangular receptacles, which contain the necessary parts of fructification. The capsule, when ripe, possesses an elastic power, by which the seeds are thrown out with considerable force.

The plant grows in Mexico and the West Indies, in Peru, Brazil, and other parts of South America. The root, which is the officinal portion, is brought chiefly from the West Indies. The term contrayerba in the Spanish language signifies *counterpoison* or *antidote*, and was applied to this root under the impression that it has the property of counteracting all kinds of poison.

Properties. The root as found in our shops is an inch or two long, of varying thickness, very hard, rough, and solid, of a reddish-brown colour externally and pale within; and has numerous long, slender, yellowish fibres attached to its inferior part. The odour is aromatic; the taste warm, slightly bitterish, and pungent. The fibres have less taste and smell than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is of a dark, brownish-red colour, and highly mucilaginous. The tincture reddens infusion of litmus, and lets fall a precipitate on the addition of water. The root has not yet been analyzed.

Medical Properties and Uses. Contrayerva is a stimulant tonic and diaphoretic, and has been given in low states of fever, malignant eruptive diseases, some forms of dysentery and diarrhœa, and other diseases requiring gentle stimulation. It is very seldom used in this country. The dose of the powdered root is about half a drachm.

CONVOLVULUS PANDURATUS. *U.S. Secondary.*

Wild Potato.

" Convolvulus panduratus. Radix. *The root.*" *U.S.*

Convolvulus. See SCAMMONIUM.

Convolvulus panduratus. Willd. *Sp. Plant.* i. 850; Barton, *Med. Bot.* i. 249. The wild potato has a perennial root, and a round, purplish, procumbent or climbing stem, which twines around neighbouring objects, and grows sometimes twelve feet in length. The leaves, which stand alternately on long petioles, are broad, heart-shaped at the base, entire, or lobed on the sides like a guitar or violin, somewhat acuminate, deep green on the upper surface, and paler beneath. The flowers are in fascicles upon long axillary peduncles. The calyx is smooth and awnless; the corolla tubular campanulate, very large, white at the border, but purplish-red at the base.

The plant is indigenous, growing throughout the United States in sandy fields, and along fences, and flowering from June to August. A variety with double flowers is cultivated in the gardens for the sake of ornament. The root is the active part of the plant.

It is very large, two or three feet in length, about three inches thick, branched at the bottom, externally of a brownish-yellow colour, and full of longitudinal fissures, internally whitish and milky, and of a somewhat acrid taste. Pursh says that he has seen a root as thick as a man's thigh.

Medical Properties. The wild potato is feebly cathartic, and has been proposed as a substitute for jalap, but is scarcely used. It is thought also to be somewhat diuretic, and has been employed, with supposed advantage, in strangury and calculous complaints. Forty grains of the dried root are said to purge gently. Perhaps an extract might be found more effectual.

W.

COPAIBA. *U.S*

Copaiba.

" Copaifera officinalis. Succus. *The juice.*" *U.S.*

Off. Syn. COPAIBA. Copaifera officinalis. Resina liquida. *Lond.;* COPAIFERÆ OFFICINALIS RESINA. Resina liquida. *Ed.;* COPAIFERA OFFICINALIS. Resina liquida. *Dub.*

Baume de copahu, *Fr.;* Copaiva-Balsam, *Germ.;* Balsamo di copaiba, *Ital.;* Balsamo de copayva, *Span.*

Copaifera. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Leguminosæ.

Gen. Ch. Calyx none. *Petals* four. *Legume* ovate. *Seed* one, with an ovate arillus. *Willd.*

The first notice to be found of the copaiba plant is that by Marcgrav and Piso, in the year 1648. Jacquin in 1763 described a species of Copaifera, which grew in the island of Martinique, and which he named *C. officinalis*, from the fact that it afforded this resinous juice. As this was believed to be the same plant with that observed by Marcgrav in Brazil, it was adopted without hesitation in the Pharmacopœias; but their identity is now denied; and Desfontaines has proposed for the officinal species the title of *C. Jaquini*, in honour of the botanist who originally described it. From recent observation and discoveries it appears, that numerous species of Copaifera exist in Brazil and other parts of South America, all of which, according to Martius, yield copaiba. Besides the C. officinalis or C. Jacquini, the following are described by Hayne;—the *C. Guianensis*, *C. Langsdorffii*, *C. coriacea*, *C. Beyrichii*, *C. Martii*, *C. bijuga*, *C. nitida*, *C. laxa*, *C. cordifolia*, *C. Jussieui*, *C. Sellowii*, *C. oblongifolia*, and *C. multijuga*. Hayne believes that the *C.* bijuga is the plant seen by Marcgrav and Piso.

Copaifera officinalis. Willd. ii. 630; Woodv. *Med. Bot.* p. 609. t. 216. *C. Jacquini.* Desfont. *Mem. du Mus.* vii. 376; Hayne, *Darstel. und Beschrieb, &c.* x. 14. This is an elegant tree, with a lofty stem, much branched at the top, and crowned by a thick canopy of foliage. The leaves are alternate, large, and pinnate, composed of from two to five pairs of ovate, entire, obtusely acuminate leaflets, two or three inches in length, rather narrower on one side than the other, smooth, pellucidly punctate, somewhat shining, and supported on short footstalks. The flowers are whitish, and disposed in terminal branched spikes. The fruit is an oval, two-valved pod, containing a single seed.

This species of Copaifera is a native of Venezuela, and grows in the province of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique, where it is said to be naturalized. Though recognised in the U.S. and British Pharmacopœias as the source of the officinal copaiba, it yields in fact little of that now in use. According to Hayne, the species from which most of the Copaiba of commerce is derived, is the *C. multijuga*, growing in the province of Para. It is probable that the *C. Guianensis*, which inhabits the neighbouring province of Guiana, especially in the vicinity of the Rio Negro, affords also considerable quantities.

The juice is obtained by making deep incisions into the stems of the trees; and the operation is said to be repeated several times in the same season. As it flows from the wound, it is clear, colourless, and very thin, but soon acquires a thicker consistence, and a yellowish tinge. It is most largely collected in the province of Para, in Brazil, and is brought to this country almost exclusively from the port of Para, in small casks or barrels.

Properties. Copaiba is a clear, transparent liquid, usually of the consistence of olive oil, of a pale yellowish colour, a peculiar not unpleasant odour, and a bitterish, hot, nauseous taste. Its specific gravity varies from 0.950 to 1.000. It is insoluble in water; but is entirely soluble in absolute alcohol, ether, and the fixed and volatile oils. With the alkalies it unites to form saponaceous compounds, which are soluble in water. Its essential constituents are volatile oil and resin, with a minute proportion of an acid which appears to be the acetic. (Durand, *Journ. of the Phil. Col. of Pharm.* i. 3.) As it contains no benzoic acid, it cannot with propriety retain its former title of *balsam of copaiva.* The substances which it most closely resembles, both in composition and properties, are the turpentines. The *volatile oil,* which constitutes from a third to one-half or more of the copaiba, may be separated by distillation. As it first comes over it is colourless, but the latter product is of a fine greenish blue. By redistillation it may be rendered wholly colourless. It is lighter than water, has the odour and taste of copaiba, and appears to contain no oxygen, as potassium is preserved in it even better than in ordinary naphtha. This fact was first noticed by Mr. Durand of Philadelphia, and has been fully confirmed in our own experience. The resinous mass which remains is hard, brittle, translucent, of a greenish-brown colour, and nearly destitute of smell and taste. By mixing it with the oil in proper proportion, we may obtain a liquid identical or nearly so with the original juice. When treated with the oil of petroleum, the resin is separated into two portions, one of which is dissolved, and may be obtained separate by evaporation, the other is left behind. The first is yellowish, hard, and brittle, and constitutes by far the largest proportion of the residuum of the distillation. The second is yellowish-brown, soft, and unctuous; and is supposed by Berzelius to result from the resinification of the volatile oil, as it is more abundant in the old than in the recent juice. Recent copaiba examined by Gerber yielded 41 per cent. of volatile oil, 51.38 of the hard and brittle resin, 2.18 of the soft resin, and 5.44 of water; while an older specimen gave 31.07 per cent. of oil, 53.68 of hard resin, 11.15 of soft resin, and 4.10 of water.

Copaiba, upon exposure to the air, assumes a deeper colour and a thicker consistence, and if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization, partly to the oxidation of the essential oil.

When triturated with about a sixteenth of its weight of magnesia, and set aside, it gradually assumes a solid consistence. (See *Pilulæ Copaibæ.*)

It is said to be frequently adulterated; but the remark is applicable rather to the markets of Europe than to those of the United States. The fixed oils are the most frequent addition, especially castor oil, which, in consequence of its solubility in alcohol, cannot, like the others, be detected by the agency of this fluid. Various plans have been proposed for ascertaining the presence of castor oil. The simplest is to boil one drachm of the copaiba in a pint of water, till the liquid is wholly evaporated. If the copaiba contain oil, the residue will be more or less soft according to the quantity present; otherwise it will be hard. Another mode, proposed by M. Planche, consists in shaking together in a bottle one part of aqua ammoniæ of the sp. gr. 0.9212 (22° Baumé) with two and a half of copaiba, at a temperature of from 50° to 60° F. The mixture, at first cloudy, quickly becomes transparent if the copaiba is pure, but remains more or less opaque if it is adulterated with castor oil. Carbonate of magnesia, caustic potassa, and sulphuric acid, have also been proposed as tests; but the two above mentioned are more certain and of easier application. Turpentine, which is said to be sometimes added to copaiba, may be detected by its smell.

Medical Properties and Uses. Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of heat in the throat and stomach, and extends an irritant action, not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to all the mucous membranes, for which it appears to have a strong affinity. The urine acquires a peculiar odour during its use. It sometimes occasions an eruption upon the skin, attended with a disagreeable itching, and tingling sensation. As a remedy it has been found most efficient in the diseases of the mucous membranes, particularly such as are of a chronic character. Thus it is given with occasional advantage in leucorrhœa, gleet, chronic dysentery, painful hemorrhoidal affections, and in chronic catarrh and other forms of bronchial disease. By Dr. La Roche, of Philadelphia, it is highly recommended in catarrh of the bladder, and in chronic irritation of the same organ. (*Am. Jour. of Med. Scien.* xiv. 13.) It is said to be used as a vermifuge in Brazil. The complaint, however, in which it is most employed is gonorrhœa. It is given in all stages of the disorder; but caution is requisite when the inflammatory symptoms are high. Even in health, if taken largely, it sometimes produces very unpleasant irritation of the urinary passages, and, by sympathy, of the testicles. It was formerly highly esteemed as a vulnerary; but is now seldom used externally.

The dose of copaiba is from twenty to thirty drops three times a day, or a smaller quantity repeated more frequently. It may be given dropped on sugar; but in this form is often so exceedingly offensive, as to render some concealment of its nauseous qualities necessary. A less disagreeable form is that of emulsion, prepared by rubbing the copaiba first with mucilage or the yolk of an egg, and sugar, and afterwards with water impregnated with some aromatic essential oil, as that of mint or cinnamon. The volatile oil may be used in the dose of ten or fifteen drops, and probably with the same effects as the copaiba, of which it is the active ingredient. The resin, which has been proposed as a substitute, is nearly inert. The pills made by means of magnesia may sometimes be resorted to with advantage.

COPTIS. *U.S. Secondary.*

Goldthread.

"Coptis trifolia. Radix. *The root.*" *U.S.*

COPTIS. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* none. *Petals* five or six, caducous. *Nectaries* five or six, cucullate. *Capsules* five to eight, stipitate, stellately diverging, and rostrate, many-seeded. *Nuttall.*

Coptis trifolia. Bigelow, *Am. Med. Bot.* i. 60; Barton, *Med. Bot.* ii. 97. This little evergreen bears considerable resemblance to the strawberry in size and general aspect. It has a perennial creeping root, which, from its slenderness and bright yellow colour, has given rise to the name of *goldthread*, by which the plant is commonly known. The caudex, from which the petioles and flower-stems proceed, is invested with ovate, acuminate, yellowish, imbricated scales. The leaves, which stand on long slender footstalks, are ternate, with firm, rounded or obovate, sessile leaflets, having an acute base, a lobed and acuminately crenate margin, and a smooth veined surface. The scape or flower-stem is slender, round, rather longer than the leaves, and surmounted by one small white flower, with a minute mucronate bracte beneath it. The petals are oblong, concave, and of a white colour; the nectaries inversely conical, hollow, and yellow at the top. The stamens have capillary filaments and globose anthers. The germs are from five to eight, stipitate, oblong, compressed, and surmounted by short recurved styles with acute stigmas. The capsules, which diverge in a star-like form, are pedicelled, compressed, beaked, and contain numerous black seeds attached to the inner side.

The goldthread inhabits the northern regions of this continent and of Asia, and is found in Greenland and Iceland. It delights in the dark shady swamps and cold morasses of northern latitudes and Alpine regions, and abounds in Canada, and in the hilly districts of New-England. Its blossoms appear in May. All parts of the plant possess more or less bitterness; but this property is most intense in the root, which is the only portion directed by the Pharmacopœia.

Dried goldthread, as brought into the market, is in loosely matted masses, consisting of the long, threadlike, orange-yellow roots, frequently interlaced, and mingled with the leaves and stems of the plant. It is without smell, and has a purely bitter taste, unattended with aroma or astringency. It imparts its bitterness and yellow colour to water and alcohol, but most perfectly to the latter, with which it forms a bright yellow tincture. Its virtues appear to depend on a bitter extractive matter, which like that of quassia, is precipitated by nitrate of silver and acetate of lead. (*Bigelow.*) It affords no evidence of containing either resin, gum, or tannin.

Medical Properties and Uses. It is a simple tonic bitter, bearing a close resemblance to quassia in its mode of action, and applicable to all cases in which that medicine is prescribed; though, from its higher price, not likely to come into general use as a substitute. In New-England it is much employed as a local application in aphthous ulcerations of the mouth; but it probably has no other virtues in this complaint than such as are common to all the simple bitters. It may be given internally in substance, infusion, or tincture. The dose of the powder is from ten to thirty grains, of a tincture prepared by macerating an ounce of the root in a pint of diluted alcohol, one fluidrachm. W.

CORIANDRUM. *U.S.*

Coriander.

"Coriandrum sativum. Semina. *The seeds.*" *U.S.*

Off. Syn. CORIANDRI SEMINA. Coriandrum sativum. Semina. *Lond.;* CORIANDRI SATIVI SEMINA. *Ed.;* CORIANDRUM SATIVUM. Semina. *Dub.*

Coriandre, *Fr;* Koriander, *Germ.;* Coriandro, *Ital.;* Cilantro, *Span.*

Coriandrum. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Corolla* radiate. *Petals* inflex-emarginate. *Universal involucre* one-leafed. *Partial involucres* halved. *Fruit* spherical. *Willd.*

Coriandrum sativum. Willd. *Sp. Plant.* i. 1448; Woodv. *Med. Bot.* p. 137. t. 53. This is an annual plant, with an erect, round, smooth, branching stem, which rises about two feet in height, and is furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnæ cut into irregular serrated lobes, resembling those of common parsley. The flowers are white or rose-coloured, and disposed in compound terminal umbels. The fruit is globular, and consists of two concave hemispherical seeds.

The *C. sativum* is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extensive cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact, that all parts of the fresh plant are extremely fetid when bruised, while the seeds become fragrant by drying. These are the officinal portion. They are brought to us from Europe.

The fruit of the coriander, as found in the shops, is globular, about the eighth of an inch in diameter, obscurely ribbed, of a grayish or brownish-yellow colour, and separable into the two seeds of which it consists. It has the persistent calyx at its base, and is sometimes surmounted by the adhering style. The smell and taste are gratefully aromatic, and depend on a volatile oil, which may be obtained separate by distillation. They are imparted to alcohol by maceration, and less readily to water.

Medical Properties and Uses. Coriander has, in a moderate degree, the ordinary medical virtues of the aromatics. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. The dose is from a scruple to a drachm.

CORNU CERVI ELAPHI. *Ed.*

Hartshorn. Stag's Horn.

Off. Syn. CORNUA. Cervus Elaphus. Cornua. *Lond.;* CORNUA CERVINA. Ramenta. *Dub.*

Corne de cerf, *Fr.;* Hirschhorn, *Germ.;* Corno di cervo, *Ital.;* Cuerno de ciervo, *Span.*

The stag or hart—*Cervus Elaphus*—the horns of which are directed by the British Colleges, is a native of Europe. Those of our own common deer—*Cervus Virginianus*—though employed in the arts, are not officinal. Hartshorn is usually imported into this country from Germany, in the state of shavings, but is very little employed.

Hartshorn shavings are without smell and taste, pliable, and of an ivory yellow colour. According to M. Merat-Guillot, they contain in 100 parts, 27 of gelatin, 57.5 of phosphate of lime, 1 of carbonate of lime, and 14.5 of water including the loss. Boiling water extracts their gelatin, forming a transparent, colourless jelly, which may be rendered palatable by the addition of sugar, lemon or orange juice, and a little wine. In its preparation, two pints of water are boiled with four ounces of the shavings to a pint, and the residue strained while hot. The clear liquid gelatinizes upon cooling. By destructive distillation, the shavings yield an impure solution of carbonate of ammonia, which formerly received the name of *spirit of hartshorn;* and the same name has been subsequently applied to similar ammoniacal solutions procured from other sources. When burnt, they leave an earthy residue consisting almost exclusively of phosphate of lime.

Medical Properties, &c. The jelly prepared from the shavings of hartshorn has been thought to possess medical virtues; but it is only nutritive and demulcent; and is probably not superior to calfsfoot jelly. The shavings themselves are used in the preparation of the Pulvis Antimonialis.

CORNUS CIRCINATA. *U.S. Secondary.*

Round-leaved Dogwood.

"Cornus Circinata. Cortex. *The bark.*" *U.S.*

Cornus. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. *Involucre* usually four-leaved. *Petals* superior, four. *Drupe* with a two-celled nut. *Willd.*

We have ten indigenous species of Cornus, all of which are supposed to possess similar medical properties; and three—the *C. Florida, C. circinata,* and *C. sericea*—have been introduced into the Pharmacopœia of the United States. The last two are placed in the secondary list, not because they are esteemed less efficient than the first; but because they have hitherto less attracted the attention of the profession.

Cornus circinata. Willd. *Sp. Plant.* i. 663. This is a shrub from six to ten feet high, with warty branches, large, roundish, pointed leaves, waved on their edges and downy beneath, and white flowers disposed in depressed cymes. The fruit is blue. The plant is a native of the United States, extending from Canada to Virginia, and growing on hill-sides and the banks of rivers. It flowers in June and July.

The bark, when dried, is in quills of a whitish or ash colour, and affords a powder resembling that of ipecacuanha. Its taste is bitter, astringent, and aromatic. In chemical composition, so far as this has been ascertained, it is analogous to the Cornus Florida. It possesses also similar medical virtues, and may be employed in the same doses. It is much used as a tonic and astringent by several physicians in Connecticut, and is highly extolled by Dr. Ives of New York, who recommends, as the most eligible preparation, an infusion made by pouring a pint of boiling water on an ounce of the coarsely powdered bark. The dose of this is from one to two fluidounces. W.

CORNUS FLORIDA. *U.S.*

Dogwood.

"Cornus Florida. Cortex. *The bark.*" *U.S.*

Cornus. See CORNUS CIRCINATA.

Cornus Florida. Willd. *Sp. Plant.* i. 661; Bigelow, *Am. Med. Bot.* ii. 73; Barton, *Med. Bot.* i. 44. This is a small indigenous tree, usually about fifteen or twenty feet in height, though sometimes not less than thirty or thirty-five feet. It is of slow growth; and the stem, which generally attains a diameter of four or five inches, is compact, and covered with a brownish bark, the epidermis of which is minutely divided by numerous superficial cracks or fissures. The branches are spreading, and regularly disposed, sometimes opposite, sometimes in fours nearly in the form of crosses. The leaves are opposite, oval, about three inches long, pointed, dark green, and sulcated on the upper surface, glaucous or whitish beneath, and marked with strong parallel veins. Towards the close of summer they are speckled with black spots, and on the approach of cold weather assume a red colour. The proper flowers are small, yellowish, and collected in heads, which are surrounded by a very large conspicuous involucre, consisting of four white obcordate leaves, having the notch at their summit tinged with red or purple. It is this involucre that constitutes the chief beauty of the tree at the period of flowering. The calyx is four-toothed, and the corolla composed of four obtuse reflexed petals. The fruit is an oval drupe of a vivid glossy red colour, containing a two-celled and two-seeded nucleus. The drupes are usually collected to the number of three or four, and remain on the tree till after the early frosts. They ripen in September.

The dogwood is found in all parts of the United States, from Massachusetts to the Mississippi and the Gulf of Mexico; but is most abundant in the Middle States. In the month of May it is clothed with a profusion of large white blossoms, which render it one of the most conspicuous ornaments of the American forests. The bark is the officinal portion, and is derived for use both from the stem and branches, and from the root. The bark of the root is preferred. It is brought into market in pieces, of various sizes, usually more or less rolled, sometimes invested with a fawn-coloured epidermis, sometimes partially or wholly deprived of it, of a reddish-gray colour, very brittle, and affording, when pulverized, a grayish powder tinged with red. The odour of dogwood is feeble, its taste bitter, astringent, and slightly aromatic. Water and alcohol extract its virtues. It has not been accurately analyzed; but from the experiments of Dr. Walker and others, appears to contain extractive matter, gum, resin, tannin, and gallic acid. A peculiar bitter principle, for which the name of *cornine* has been proposed, has been announced as an ingredient by Mr. Carpenter; but we need more definite information on the subject. The flowers of the *C. Florida* have the same bitter taste as the bark, and though not officinal, are sometimes employed for the same purposes.

Medical Properties and Uses. Cornus Florida is tonic and astringent. By Dr. Walker it was found, when taken internally, to augment the force and frequency of the pulse, and increase the heat of the body. It is thought to possess remedial properties closely analogous to those of Peruvian bark, for which it has occasionally been successfully substituted in the treatment of intermittent fevers; but the introduction of sulphate of quinia into use, has nearly banished this, as well as many other substitutes for cinchona, from regular practice. The dogwood has also been employed with supposed benefit in typhoid fevers, and other complaints for which the Peruvian tonic is usually prescribed.

It may be given in powder, decoction, or extract. The dose of the powder is from a scruple to a drachm, repeated in cases of intermittent fever, so that from one to two ounces may be taken in the interval between the paroxysms. The decoction is officinal. (See *Decoctum Cornûs Floridæ.*) The dried bark is said to be preferable to the fresh; as it possesses all the activity of the latter, without being equally liable to offend the stomach and bowels.

Off. Prep. Decoctum Cornûs Floridæ. *U.S.* W.

CORNUS SERICEA. *U.S. Secondary.*

Swamp Dogwood.

"Cornus sericea. Cortex. *The bark.*" *U.S.*

Cornus. See CORNUS CIRCINATA.

Cornus sericea Willd. *Sp. Plant.* i. 663; Barton, *Med. Bot.* i. 115. This species of Cornus is usually six or eight feet in height, with numerous erect stems, which are covered with a shining reddish bark, and send out opposite spreading branches. The young shoots are more or less pubescent. The leaves are opposite, petiolate, ovate, pointed, entire, and on the under surface covered with soft brownish hairs. The flowers are small, white, and disposed in terminal cymes, which are depressed and woolly. The fruit consists of globular, berry-formed drupes, of a cerulean blue colour, and collected in bunches.

The swamp dogwood inhabits the United States from Canada to Carolina, and is found in moist woods, in swamps, and on the borders of streams. It flowers in June and July. The bark was ascertained by Dr. Walker to have the same medical properties with that of the Cornus Florida. It may be given in the same doses, and administered in a similar manner.

W.

COTULA. *U.S. Secondary.*

May-weed.

"Anthemis cotula. Planta. *The plant.*" *U.S.*

Camomille puante, Maroute, *Fr.;* Hunds-Kamille, Stinkende-Kamille, *Germ.;* Camomilla fetida, Cotula, *Ital.;* Manzanilla loca, *Span.*

Anthemis. See ANTHEMIS.

Anthemis Cotula. Willd. *Sp. Plant.* iii. 2181; Barton, *Med. Bot.* i. 161. The May-weed is an annual plant, with a fibrous root, and an erect striated stem, very much branched even to the bottom, from one to two feet in height, and supporting alternate, sessile, flat, doubly pinnated, somewhat hairy leaves, with pointed linear leaflets. The flowers stand singly upon the summits of the branches, and consist of a central, convex, golden-yellow disk, with white radial florets, which spread horizontally during the day, but are reflexed or bent towards the stem at night. The calyx, which is common to all the florets, is hemispherical, and composed of imbricated hairy scales. The receptacle is conical or nearly cylindrical, and surmounted by rigid, bristle-shaped paleæ, shorter than the florets. The seeds are naked.

This plant grows abundantly both in the United States and in Europe. In this country, it is found in the vicinity of inhabited places, growing among rubbish, along the sides of roads, and in waste grounds. Notwithstanding its extensive diffusion, it is generally believed to be a naturalized, not an indigenous plant. It is frequently called *wild chamomile*. It flowers from the middle of summer till late in autumn.

The whole plant has a strong, disagreeable smell, and a warm, bitter taste, and imparts these properties to water. We are not aware that its analysis has been attempted.

The medical properties of this species of Anthemis are essentially the same with those of chamomile, for which it may be employed as a substitute; but its disagreeable odour is an obstacle to its general use. On the continent of Europe, it has been given in nervous diseases, especially hysteria, under the impression, probably derived from its peculiar smell, that it possesses antispasmodic powers. It has also been thought to be emmenagogue. In the French Codex, it is ranked among the officinals; but neither of the British Colleges has adopted it, though abundant in Great Britain. In this country it is scarcely employed, except as a domestic remedy. The whole plant is active; but the flowers, being less disagreeable than the leaves, are preferred for internal use. The remedy is best administered in the state of infusion. W.

◆

CROCUS. *U.S.*

Saffron.

"Crocus sativus. Stigmata. *The stigmas.*" *U.S.*

Off. Syn. CROCI STIGMATA. Crocus sativus (Anglicus). Stigmata. *Lond.;* CROCI SATIVI STIGMATA. *Ed.;* CROCUS SATIVUS. Stigmata. *Dub.*

Safran, *Fr., Germ.;* Zafferano, *Ital.;* Azafran, *Span.*

Crocus. *Sex. Syst.* Triandria Monogynia.—*Nat. Ord.* Irideæ.

Gen. Ch. Corolla six parted, equal. *Stigmas* convoluted. *Willd.*

Crocus sativus. Willd. *Sp. Plant.* i. 194; Woodv. *Med. Bot.* p. 763. t. 259. The common cultivated saffron is a bulbous, perennial plant. From the bulb, which is rounded and depressed, the flower rises a little above the ground upon a long, slender, white, and succulent tube. It is large, of a beautiful lilac or bluish-purple colour, and makes its appearance in September or October. The leaves are radical, linear, slightly revolute, dark green upon their upper surface with a white longitudinal furrow in the centre, paler underneath with a prominent flattened midrib, and enclosed at their base, together with the tube of the corolla, in a membranous sheath, from which they emerge soon after the appearance of the flower. The style hangs out on one side between two segments of the corolla, and terminates in three long convoluted stigmas, which are of a rich orange colour, highly odorous, rolled in at the edges, and notched at the summit. These stigmas are the officinal part of the plant.

Botanists have found much difficulty in deciding which of the plants belonging to this genus are mere varieties of the *C. sativus*, and which are distinct species. Linnæus considered them all as varieties of the officinal species, but the *vernal crocus* is now almost universally recognised as distinct; and the number of species has been greatly multiplied by some authors.

The C. sativus, or *autumnal crocus*, is a native of Greece and Asia Minor, where it has been cultivated from the earliest ages of antiquity. It is also cultivated for medicinal use in Sicily, Spain, France, England, and other temperate countries of Europe. In Great Britain it has been found growing wild, but is not thought to be indigenous. Large quantities of saffron are raised in Egypt, Persia, and Cashmere, whence it is sent to India. We cultivate the plant in this country chiefly, if not solely, as a garden flower.

In England the flowers appear in October, and the leaves continue green through the winter; but the plant does not ripen its seed, and is propagated by offsets from the bulb. These are planted in grounds prepared for the purpose, and are arranged either in rows, or in small patches at certain distances. The flowers are gathered soon after they show themselves, as the period of flowering is very short. (*Fée.*) The stigmas, or summits of the pistils, are separated from the remainder of the flower, and carefully dried by artificial heat. During this process they are sometimes made to assume the form of a cake by pressure; but the finest saffron is that which has been dried loosely. Five pounds of the fresh stigmas yield one pound of the dried. (*Duncan.*) A field planted with saffron continues to be productive for three years.

The English saffron is most highly esteemed in this country. That imported from Spain is often impregnated with oil, said to be added under the impression that it conduces to the preservation of the drug. It is probable that the produce of other countries is sometimes sold under the name of English saffron. Much is imported from Gibraltar packed in canisters; and parcels are occasionally brought from Trieste and other ports of the Mediterranean.

The high price of this medicine gives rise to frequent adulterations. Water is said to be very often added in order to increase its weight. Sometimes the flowers of other plants, particularly the *Carthamus tinctorius* or safflower, and the *Calendula officinalis* or officinal marygold, are fraudulently mixed with the genuine stigmas. They may be known by their shape, which is rendered obvious by throwing a portion of the suspected mass into hot water, which causes them to expand. Other adulterations are the fibres of dried beef, the stamens of the Crocus distinguishable by their yellow colour, the stigmas previously exhausted in the preparation of the infusion or tincture, and various mineral substances easily detected upon close examination.

In the purchase of this medicine in cakes, those should be selected which are close, tough, and firm in tearing. Saffron should not be very moist, nor very dry, nor easily pulverized; nor should it emit an offensive smell when thrown on live coals. The freshest is the best, and that which is less than a year old should, if possible, be selected. It should possess in a high degree the characteristic properties of colour, taste, and smell. If it does not colour the fingers when rubbed between them, or has an oily feel, or a musty flavour, or a black, yellow, or whitish colour, it should be rejected.

As its activity depends, partly at least, on a volatile ingredient, it should be kept in well-stopped vessels. Some recommend that it should be enclosed in a bladder, and introduced into a tin case.

Properties. Saffron has a peculiar, sweetish, aromatic odour, a warm, pungent, bitter taste, and a rich deep orange colour, which it imparts to the saliva when chewed. Analyzed by Vogel and Bouillon-Lagrange, it afforded a very large proportion of a peculiar extractive matter, an odorous volatile oil, wax, gum, albumen, a small quantity of saline matter, besides water, and vegetable fibre. The extractive matter was named by them *polychroïte*, from the changes of colour which it undergoes by the action of reagents. It is prepared by evaporating the watery infusion to the consistence of honey, digesting the residue in alcohol, filtering the tincture, and evaporating it to dryness. Thus obtained, it is in the form of a reddish-yellow mass, of an agreeable smell, slightly bitter, soluble in water and alcohol, and somewhat deliquescent. Its solution becomes grass green by the action of nitric acid, blue and then violet by that of sulphuric acid, and loses its colour altogether on exposure to light, and by chlorine. According to M. Henry, Sen., it contains about 20 per cent. of volatile oil, which can be separated only by the agency of an alkali. When perfectly pure, it is of a brilliant red colour, soluble with difficulty in water which it renders yellow, and readily soluble in alcohol, and the fixed and volatile oils. M. Henry states that this colouring matter constitutes 42 per cent. of saffron, and the essential oil 10 per cent. It is to the latter that the medicine owes its active properties. It may be partially separated by distillation.

Medical Properties and Uses. Saffron was formerly considered highly stimulant and antispasmodic. It has been alleged, that in small doses it moderately excites the different functions, exhilarates the spirits, relieves pain, and produces sleep; in large doses, gives rise to headach, intoxication, delirium, stupor, and other alarming symptoms; and Shrœder asserts, that in the quantity of two or three drachms it proves fatal. It was thought also to act powerfully on the uterine system, promoting menstruation. The ancients employed it extensively, both as a medicine and condiment, under the name of *crocus*. It was also highly esteemed by the Arabians, and enjoyed considerable reputation among the physicians of modern Europe till within a comparatively recent period. On the continent it is still much used as a stimulant and emmenagogue. But the experiments of Dr. Alexander have proved it to possess little activity as a medicine; and in Great Britain and the United States it is seldom prescribed. By old women and nurses saffron tea is frequently used in exanthematous diseases, to promote the eruption; a practice introduced by the humoral pathologists, but afterwards abandoned by the profession, and not greatly injurious only from the inactivity of the medicine. The chief use of saffron at present is to impart colour and flavour to officinal tinctures. From ten to thirty grains may be given for a dose.

CUBEBA. *U.S.*

Cubebs.

"Piper cubeba. Fructus. *The fruit.*" *U.S.*

Off. Syn. CUBEBA. Piper Cubeba. Baccæ. *Lond.;* CUBEBA. PIPER CUBEBA. Fructus. *Dub.*

Cubebe, *Fr.;* Kubeben, *Germ.;* Cubebe, *Ital.;* Cubebas, *Span.;* Kebabeh, *Arab.*

PIPER. *Sex. Syst.* Diandria Trigynia.—*Nat. Ord.* Piperaceæ.

Gen. Ch. Calyx none. *Corolla* none. *Berry* one-seeded. *Willd.*

Piper Cubeba. Willd. *Sp. Plant.* i. 159. This is a climbing perennial plant, with a smooth, flexuous, jointed stem, and entire, ovate, oblong or lanceolate leaves, which in the old vine are unequal at the base, less than an inch long, and supported upon short channeled footstalks. The flowers are pedicelled, and form long, pendent spikes. The fruit is a berry which grows in clusters.

This species of Piper is a native of Java, where it grows luxuriantly in the woods, and furnishes much of the cubebs of commerce. It flourishes also in Nepaul; and is said to be found in the Isles of Bourbon and France, and in Guinea. It is not cultivated.

Properties. Cubebs are round, about the size of a small pea, of a blackish or grayish-brown colour, and furnished with a short stalk, which appears to be continuous with raised veins that run over the surface of the berry, and embrace it like a net work. The shell is hard, almost ligneous, and contains within it a single loose seed, covered with a blackish coat, and internally white and oleaginous. The odour of the berry is agreeably aromatic; the taste, warm, bitterish, and camphorous, leaving in the mouth a peculiar sensation of coolness, like that produced by the oil of peppermint. The powder is dark coloured, and of an oily aspect. From 1000 parts of cubebs, M. Monheim obtained 30 parts of a ceruminous substance, 25 of a green volatile oil, 10 of a yellow volatile oil, 45 of *cubebin*, 15 of a balsamic resin, 10 of chloride of sodium, 60 of extractive, and 650 of lignin, with 155 parts lost. The cubebin appears to be identical with piperin.—(*Journ. de Pharm.* xx. 403.) The oil may be obtained separate by distillation with water. It is colourless, yellowish, or greenish, of a feeble aromatic odour, of a warm camphorous aromatic taste, lighter than water, and of a consistence approaching that of almond oil. Exposed to the air it is said to thicken without losing its odour. It sometimes deposites crystals upon standing. Baumé obtained two ounces and two drachms from twelve and a half pounds (French weight) of the berries. (*Fée.*) To Schönwald, ten pounds of the berries yielded eleven ounces of oil. (*Duncan.*) Cubebs gradually deteriorate by age; and in the state of powder become rapidly weaker, in consequence of the escape of their active volatile ingredient. They should always be kept whole, and pulverized at the time of dispensing them. The powder is said to be sometimes adulterated with that of pimento.

Medical Properties and Uses. Cubebs are gently stimulant, with a special direction to the urinary organs. In considerable quantities they usually excite the circulation, increase the heat of the body, and sometimes occasion headach and giddiness. At the same time they frequently produce an augmented flow of the urine, to which they impart a peculiar odour. Nausea and moderate purging are also occasional attendants upon their operation; and they are said to give rise to a sense of coolness in the rectum during the passage of the feces. We have no evidence that they were known to the ancients. They were probably first brought into Europe by the Arabians; and were formerly employed for similar purposes with the black pepper; but they were found much less powerful and fell into disuse. Some years since they were again brought into notice in England as a remedy in gonorrhœa, and have been found very efficient in this complaint by numerous practitioners, not only of Great Britain, but of the continent of Europe and of the United States. This application of cubebs was derived from India, where they have long been used in gonorrhœa, gleet, and leucorrhœa, and as a grateful stomachic and carminative in disorders of the digestive organs. They are said to have occasionally produced swelled testicle when given in the first mentioned complaint; and though recommended in all its stages, will probably be found most safe and effectual in cases where the inflammatory action is confined to the mucous membrane of the urethra. If not speedily useful, they should be discontinued. They are best administered in the form of powder, of which the dose is from one to three drachms, repeated three or four times a day. The volatile oil is sometimes substituted in the dose of ten or twelve drops, suspended in water by the intervention of sugar.

In Loudon's Encyclopædia of Plants it is stated, that the berries of the Uvaria Zeylanica of Ceylon are used as a specific for gonorrhœa, under the name of cubebs. They are, however, wholly different from the genuine drug; and may be distinguished by containing four seeds in each berry, while the latter has but one. W.

◆

CUMINI SEMINA. *Lond.*

Cumin Seed.

"Cuminum Cyminum. *Semina.*" *Lond.*

Cumin, *Fr.;* Römischer Kümmel, *Germ.;* Comino, *Ital., Span.*

Cuminum. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Fruit* ovate, striated. *Partial umbels* four. *Involucres* four-cleft.

Cuminum Cyminum. Willd. *Sp. Plant.* i. 1440; Woodv. *Med. Bot.* p. 142. t. 56. This is an annual plant, about six or eight inches high, having a round, slender, branching stem, with numerous narrow, linear, pointed, smooth, grass-like leaves, of a deep green colour. The flowers are white or purple, and disposed in numerous terminal umbels, which have very few rays, and are attended with general and partial involucres, consisting of three or four linear leaflets. The fruit consists of two oblong plano-convex seeds, united by their flat sides. The plant is a native of Egypt, but is cultivated for its seeds in Sicily, Malta, and other parts of Europe.

The cumin seeds of the shops are elliptical, flat on one side, convex, furrowed, and rough on the other, about one-sixth of an inch in length, and of a light-brown colour. Two are sometimes united together as upon the plant. Their odour is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain much essential oil, which is lighter than water, of a yellowish colour, and has the sensible properties of the seeds.

Medical Properties and Uses. In medical properties they resemble the other aromatic seeds of umbelliferous plants, but are more stimulating. They are seldom used in the United States, and appear to be retained by the London College, merely as an ingredient in a stimulant and discutient officinal plaster.

Off. Prep. Emplastrum Cumini. *Lond.* W.

CUPRUM.

Copper.

Cuivre, *Fr.;* Kupfer. *Germ.;* Rame, *Ital.;* Cobre, *Span.*

This metal is not officinal in the metallic state, in which it is never used in medicine; but it furnishes several important preparations.

Copper is very generally diffused in nature, and exists principally in four states; as native copper, as an oxide, as a sulphuret, and as a salt. Its principal native salts are the sulphate, carbonate, arseniate, and phosphate. In the United States it has been found in various localities, but most abundantly in New-Jersey, and in the North-West Territory. The principal copper mines in the world, are those of the Pyrenees in France, Cornwall in England, and Fahlun in Sweden.

Properties. Copper is a brilliant, sonorous metal, of a reddish colour, and very ductile, malleable, and tenacious. It has a slightly nauseous taste, and emits a disagreeable smell when rubbed. Its texture is granular, and its fracture hackly. Its sp. gr. is 8.89, and its fusing point, 1996 F. according to Daniell; being intermediate in fusibility between silver and gold. Its equivalent number is 31.6. Exposed to the air it undergoes a slight tarnish. Its combinations are numerous and important. With oxygen it forms two well characterized oxides, a suboxide, or dioxide, of a red colour, consisting of two equiv. of copper and one of oxygen; and a protoxide of a black colour, formed of one equiv. of metal and one of oxygen. The latter oxide, which alone is salifiable, forms with acids several salts, important in medicine and the arts. With metals copper forms numerous alloys, of which that with zinc, called brass, is the most useful. When copper is in solution, it may be readily detected by the immersion of a bright plate of iron, which immediately becomes covered with a film of metallic copper.

Action on the Animal Economy. Copper, in its pure state, is perfectly inert; but in combination is highly deleterious. Nevertheless a trace of it has been detected by M. Sarzeau in the blood. Its combinations when taken in poisonous doses, produce a coppery taste in the mouth; nausea and vomiting; violent pain of the stomach and bowels; frequent, black, and bloody stools; small, irregular, sharp, and frequent pulse; faintings; burning thirst; difficulty of breathing; cold sweats; paucity of urine; violent headach; cramps, convulsions, and finally death. The best treatment in cases of poisoning by copper, is to neutralize the poison by the whites of eggs, diffused in water, and administered in large and repeated doses. If this remedy be not at hand, the patient must in the mean time be gorged with warm or even cold water, or with some emollient decoction, and the throat irritated by the finger or a feather, with a view to excite vomiting. Should vomiting not take place by these means, the stomach-pump may be employed. Sugar, formerly recommended as an antidote by Orfila on the authority of M. Marcelin Duval, is now considered by the former to have the power merely of calming irritation after vomiting has taken place, and to be far inferior to albumen, which, by decomposing the cupreous preparation, acts as a true counterpoison.

After the foregoing statements we need hardly add, that the use of vessels of copper should be discontinued in all operations connected with pharmacy and domestic economy; for although the metal, uncombined, is innocuous, yet the risk is great that they may be acted on, in which event, whatever may be contained in them would be rendered deleterious.

Pharm. Prep. The following is a list of all the preparations containing copper, in the U. S. and British Pharmacopœias, arranged so as to exhibit the synonymes.

CUPRI ACETAS. *U.S.*

Acetate of Copper.

Off. Syn. ÆRUGO, *Lond.;* SUB-ACETAS CUPRI, *Ed.;* CUPRI SUBACETAS, *Dub.*

Verdigris; Acetate de cuivre brut, Vert-de-gris, *Fr.;* Grünspan, *Germ.;* Verde rame, *Ital.;* Cardenillo, *Span.*

Preparation. Verdigris is prepared in large quantities in the South of France, more particularly in the neighbourhood of Montpelier. It is also manufactured in Great Britain and Sweden. In France the process is conducted in the following manner. Sheets of copper are stratified with the refuse of the grape which remains after the expression of the juice in making wine, and allowed to remain in this state for a month or six weeks. At the end of this time, the plates are found coated with a considerable quantity of verdigris. This is scraped off, and the plates are then replaced as at first, to be further acted on. The scrapings thus obtained form a paste, which is afterwards well beaten with wooden mallets, and packed in oblong leathern bags, about ten inches in length by eight in breadth, in which it is dried in the sun, until the loaf of verdigris, as it is called, attains the proper degree of hardness. The rationale of the process is easily understood. The grape-refuse contains a considerable quantity of juice, which, by contact with the air, undergoes the acetous fermentation. The copper becomes oxidized, and by subsequent combination with the acetic acid generated during the fermentation, forms the acetate of copper or verdigris. In England a purer verdigris is prepared by covering copper plates with cloth soaked in pyroligneous acid.

Verdigris comes to this country exclusively from France, being imported principally from Bordeaux and Marseilles. The leathern packages in which it is put up, called sacks of verdigris, weigh generally from twenty-five to thirty pounds, and arrive in casks, each containing from thirty to forty sacks.

Properties. Verdigris is in masses, of a pale green colour, and composed of a multitude of minute silky crystals. Sometimes, however, it occurs of a bright blue colour. Its taste is coppery. It is insoluble in alcohol, and by the action of water, a portion of it is resolved into the neutral acetate which dissolves, and a subacetate, containing three equiv. of base, which remains behind in the form of a dark green powder, gradually becoming black. It is hence evident, that when verdigris is prepared by levigation with water, it is altered in its nature. The neutral acetate is the crystallized acetate of copper of the Dublin College (see *Cupri Acetas. Crystalli*); while the above mentioned subacetate may be viewed as identical with the prepared verdigris (see *Cupri Acetas Præparatus*). When acted on by sulphuric acid, it is decomposed with effervescence, vapours of acetic acid being evolved, easily recognised by their vinegar odour. The verdigris of commerce generally contains from a half to two per cent. of impurities, consisting of particles of copper, and the husks and stones of the grape. When of good quality, it has a lively green colour, is free from black or white spots, and is dry and difficult to break. The green rust, called in popular language verdigris, which copper vessels are apt to contract when not kept clean, is a carbonate of copper, and must not be confounded with real verdigris.

Composition. Verdigris, apart from its impurities, is a variable mixture of the subacetates of copper; the sesquibasic acetate characterizing the green variety, the diacetate the blue. When acted on by water, the portion consisting of diacetate is converted into soluble neutral acetate, and insoluble tribasic acetate, as above mentioned.

Medical Properties and Uses. Verdigris acts as an emetic, and is said also to possess tonic properties. As an emetic it is prompt in its action, and not without danger. Externally it acts as a detergent and escharotic, and is occasionally applied to ulcers attended with fungus, or to callous edges. Its dose as a tonic is from an eighth to a quarter of a grain, and as an emetic, from one to two grains; but it is very seldom employed internally; and considering its irritating nature, it has very properly fallen into disuse. For its effects as a poison, and the mode of treatment, the reader is referred to the article *Cuprum.*

CUPRI ACETAS. Crystalli. *Dub.*

Crystals of Acetate of Copper.

Distilled verdigris, Crystals of Venus, neutral acetate of copper; Cristaux de Vénus, Verdet crystallisé, *Fr.;* Destillirter Grünspan, Kupferkrystallen, *Germ.*

Crystallized acetate of copper is prepared principally at Montpelier in France. The verdigris which is made in private houses is collected and carried to the manufactory. It is there dissolved in vinegar by the assistance of heat, and the solution, after having been sufficiently concentrated, is transferred to suitable vessels, where it crystallizes on cooling. The crystallization is facilitated by inserting sticks in the liquid, split in four longitudinally, the several portions being kept apart by small wedges of wood. On these the crystals are deposited.

This salt has a deep blue colour and strong styptic taste, crystallizes in rhomboidal prisms, and effloresces slightly in the air. It dissolves in water without residue, a character which serves to distinguish it from verdigris. It consists of one equivalent of acetic acid, one of protoxide of copper, and one of water. Its popular name of distilled verdigris is highly improper, as no distillation is practised in its preparation.

Medical and Pharmaceutical Uses. It is not very obvious for what reason the Dublin College has included this among its officinal preparations. It possesses similar medical properties with verdigris; but being more active and poisonous, must be used in smaller doses. It is sometimes used in pharmacy for the purpose of obtaining acetic acid, which may be disengaged from it by the action of sulphuric acid; and the larger proportional quantity of acetic acid which it contains, makes it more eligible for this purpose than verdigris. It enters into no officinal preparation. B.

CUPRI SULPHAS. *U.S., Lond., Dub.*

Sulphate of Copper.

Off. Syn. SULPHAS CUPRI. *Ed.*

Blue vitriol; Sulfate de cuivre, Vitriol bleu, Couperose bleu, *Fr.;* Schwefelsaures Kupfer, Kupfervitriol, Blauervitriol, Blauer Galitzenstein, *Germ.;* Rame solfato, Vitriolo di rame, Vitriolo di Cipro, *Ital.;* Sulfato de cobre, Vitriolo azul, *Span.*

Preparation, &c. Sulphate of copper occasionally exists in nature, and generally in solution in the water which flows through copper mines. It is obtained artificially by three principal methods. One method consists in merely evaporating the waters which naturally contain the salt in solution. Another is to roast the native sulphuret in a reverberatory furnace, whereby it is made to pass, by absorbing oxygen, into the state of sulphate. The roasted mass is lixiviated, and the solution obtained evaporated that crystals may form. The salt procured by either of these methods, contains a little sulphate of the peroxide of iron, from which it may be freed by adding an excess of protoxide of copper, which has the effect of precipitating the iron. The third method alluded to is pursued in France. It consists in wetting, and then sprinkling with sulphur, sheets of copper, which are next heated to redness for some time, and afterwards plunged into water while yet hot. The same operation is repeated until the sheets are entirely corroded. At first a sulphuret is formed, which by the action of heat and air gradually passes into the state of sulphate. This is dissolved in the water, and is obtained in crystals by evaporation.

On account of the duty upon sulphate of copper, none of it is at present imported into the United States, the whole demand being supplied from our own laboratories. The process for making it generally pursued in this country, is by direct combination between old scrap copper and sulphuric acid.

Properties. Sulphate of copper has a rich deep-blue colour and strong metalline styptic taste. It reddens vegetable blues, and crystallizes in large, transparent, rhomboidal prisms, which effloresce slightly in the air, and are soluble in four parts of cold, and two of boiling water, but insoluble in alcohol. When heated, it first melts in its water of crystallization, and then dries and becomes white. If the heat be increased, it next undergoes the igneous fusion; and finally, at a high temperature, loses its acid, protoxide of copper being left. Potassa, soda, and ammonia throw down from it a bluish-white precipitate of hydrated protoxide of copper, which is immediately dissolved by an excess of the last mentioned alkali, forming a rich deep-blue solution, called in early pharmacy, *aqua sapphirina.* It is also decomposed by the alkaline carbonates, and by a number of important salts, such as borax, acetate and subacetate of lead, acetate of iron, nitrate of silver, corrosive chloride of mercury, tartrate of potassa, and muriate of lime; and it is precipitated by all astringent vegetable infusions. Of course it must not be associated in prescription with any of these substances. It consists of one equivalent of sulphuric acid, one of protoxide of copper, and five of water.

Medical Properties. Sulphate of copper, in small doses, is deemed astringent and tonic; in large ones, a prompt emetic. With a view to its tonic effect it has been given in intermittent fever, as well as in epilepsy and some other spasmodic diseases; and as an emetic, for discharging poisons from the stomach, especially opium. It has been used also as an emetic in incipient phthisis, but its effects in that disease are probably worse than useless. In croup it has been employed as an emetic with encouraging success in a number of cases by Drs. Serlo and Malin. In one case in which the ordinary remedies were tried without affording much relief, a cure was effected by an emetic of the sulphate, which produced the discharge of the false membrane. (*N. Amer. Arch.* I. 159, from *Hufeland's Journal* for Jan. 1834.) In small doses it has of late been highly recommended in chronic diarrhœa. Externally it is employed in solution as a stimulant to ill-conditioned ulcers, as an escharotic for destroying warts, fungus, and callous edges, and as a styptic to bleeding surfaces. In weak solution, either alone or associated with other substances, it forms a useful collyrium in the chronic stages of some forms of ophthalmia. Eight grains of it, mixed with an equal weight of Armenian bole, and two grains of camphor, and added to half a pint of boiling water, forms, after becoming limpid by standing, a collyrium strongly recommended by Mr. Ware, as a substitute for *Bates's Aqua Camphorata*, in the purulent ophthalmia of infants. The dose as a tonic is a quarter of a grain, gradually increased; as an emetic, from two to five grains. Orfila cautions against giving large doses of this salt as an emetic in cases of poisoning, as it is apt, from its poisonous effects, to increase the mischief. Upon the whole, such is the activity of the sulphate of copper, that it ought to be exhibited with the greatest caution. For its effects as a poison, see *Cuprum.*

CURCUMA. *U.S. Secondary.*

Turmeric.

"Curcuma longa. Radix. *The root.*" *U.S.*

Off. Syn. CURCUMA LONGA. Radix. *Dub.*

Safran des Indes, *Fr.;* Kurkuma, Gilbwurz, *Germ.;* Curcuma, *Ital.*, *Span.;* Zirsood *Arab.;* Huldie, *Hindoo.*

Curcuma. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Scitamineæ.

Gen. Ch. Both limbs of the corolla three-partite. *Anther* with two spurs at the base. *Seeds* with an arillus. *Loudon's Encyc.*

The roots of several species of Curcuma have been employed in medicine. Two varieties of *zedoary*—an aromatic tonic formerly admitted into the officinal lists of the London and Dublin Colleges, but now discarded—are ascribed to this genus, one to the *C. Zedoaria* of Roscoe, the other to the *C. Zerumbet* of Roxburgh. We are informed that from the tubers of several species, a very pure starch, similar to arrow-root, is prepared, and used in some parts of India, especially in Travancore. But the only species at present acknowledged as officinal, in either of the British Pharmacopœias, or in our own, is the *C. longa*, or turmeric plant.

Curcuma longa. Willd. *Sp. Plant.* i. 14; Woodv. *Med. Bot.* p. 737. t. 252. The root of this plant is perennial, tuberous, palmate, and internally of a deep yellow or orange colour. The leaves are radical, large, lanceolate, obliquely nerved, sheathing at their base, and closely embrace each other. The scape or flower-stem, which rises from the midst of the leaves, is short, thick, smooth, and constitutes a spike of numerous imbricated bracteal scales, between which the flowers successively make their appearance. The plant is a native of the East Indies and Cochin-China, and is cultivated in various parts of Southern Asia, particularly in Bengal and Java, whence the root is exported.

The dried root is in cylindrical or oblong pieces, about as thick but not as long as the finger, tuberculated, somewhat contorted, externally yellowish-brown, internally deep orange-yellow, hard, compact, and breaking with a fracture like that of wax. Another variety, comparatively rare, is round or oval, about the size of a pigeon's egg, and marked externally with numerous annular wrinkles. It is distinguished by the name of *curcuma rotunda*, the former being called *curcuma longa*. The two varieties have a close resemblance in sensible properties, and are thought to be derived from the same plant, though formerly ascribed to different species of Curcuma. The odour of tumeric is peculiar; the taste warm, bitterish, and feebly aromatic. It tinges the saliva yellow, and affords an orange-yellow powder. Analyzed by Pelletier and Vogel, it was found to contain lignin, starch, a peculiar yellow colouring matter, a brown colouring matter, gum, an odorous and very acrid volatile oil, and a small quantity of muriate of lime. The peculiar colouring principle is reddish-brown in the concrete state, yellow when minutely divided, heavier than water, of an acrid and pungent taste like that of pepper, but slightly soluble in water, very soluble in alcohol, ether, and the oils. The alkalies rapidly change its colour to a reddish-brown; and paper tinged with tincture of turmeric is employed as a test of the presence of these bodies. Berzelius, however, states that its colour is changed to red or brownish-red by the concentrated mineral acids, by pure boracic acid, especially when dissolved in alcohol, and by numerous metallic salts; so that its indications cannot be certainly relied on. Turmeric is used for dyeing yellow; but the colour is not permanent.

Medical Properties, &c. This root is a stimulant aromatic, bearing some resemblance to ginger in its operation, and is much used in India as a condiment. It is a constant ingredient in the curries so generally employed in the East. In former times it had some reputation in Europe as a remedy in jaundice and other visceral diseases; but at present is employed only to impart colour to ointments, and other pharmaceutic preparations. W.

CYDONIÆ SEMINA. *Lond.*

Quince Seeds.

"Pyrus Cydonia. *Semina.*" *Lond.*.

Semences de coings, *Fr.;* Quittenkerne, *Germ.;* Semi di cotogno, *Ital.;* Simiente de membrillo, *Span.*

The quince tree has been separated from the genus *Pyrus* and erected into a new one with the title *Cydonia,* which is now generally admitted by botanists. It differs from the Pyrus in the circumstance that the cells of its fruit contain many seeds, instead of two only as in the latter.

Cydonia. *Sex. Syst.* Icosandria Pentagynia.—*Nat. Ord.* Pomaceæ.

Gen. Ch. *Calyx* five-parted, with leafy divisions. *Apple* closed, many-seeded. *Testa* mucilaginous. *Loudon's Encyc.*

Cydonia vulgaris. Pers. *Enchir.* ii. 40.—*Pyrus Cydonia.* Willd. *Sp. Plant.* ii. 1020; Woodv. *Med. Bot.* p. 505. t. 182. The common quince tree is characterized as a species by its downy deciduous leaves. It does not require particular description. It is supposed to have been originally obtained from Crete, but grows wild in Austria, on the banks of the Danube. It is abundantly cultivated in this country. The fruit is about the size of a pear, yellow, downy, of a pleasant odour, a rough, astringent, acidulous taste; and in each of its five cells contains from eight to fourteen seeds. Though not eaten in its raw state, it forms a very pleasant confection; and a syrup prepared from it may be used as a grateful addition to drinks in sickness, especially in looseness of the bowels, which it is supposed to restrain by its astringency. The seeds are the officinal portion.

They are ovate, angled, of a reddish-brown colour externally, white within, inodorous, and nearly insipid, being slightly bitter when long chewed. Their coriaceous envelope, abounds in mucilage, which is extracted by boiling water. Two drachms of the seeds are sufficient to render a pint of water thick and ropy. It has been proposed by a German pharmaceutist to evaporate the decoction to dryness, and powder the residue. Three grains of this powder form a sufficiently consistent mucilage with an ounce of water

Medical Properties, &c. The mucilage of quince seeds may be used for all the purposes to which other mucilaginous liquids are applied. It is preferred by some practitioners as a local application in conjunctival ophthalmia; but in this country is less used for this purpose than the infusion of sassafras pith.

Off. Prep. Decoctum Cydoniæ, *Lond.* W.

DELPHINIUM. *U.S. Secondary.*

Larkspur.

"Delphinium consolida. Radix. *The root.*" *U.S.*

Pied d'allouette, *Fr.;* Feld-Rittersporn, *Germ.*

Delphinium. *Sex. Syst.* Polyandria Trigynia—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* none. *Petals* five. *Nectary* bifid, horned behind. *Pods* three or one. *Willd.*

Delphinium consolida. Willd. *Sp. Plant.* ii. 1226; Loudon's *Encyc. of Plants*, p. 473. 7832. The larkspur is a showy annual plant, with an erect, branched, slightly pubescent stem. Its leaves are divided into linear segments, widely separated, and forked at the summit. The flowers are usually of a beautiful azure blue colour, and disposed in loose terminal racemes, with peduncles longer than the bractes. The nectary is one-leaved, with an ascending horn nearly equalling the corolla. The seeds are contained in smooth, solitary capsules.

This species of larkspur has been introduced from Europe into this country, where it has become naturalized, growing in the woods and fields, and flowering in June and July.

Various parts of the larkspur have been employed in medicine; and the plant is said to have properties closely analogous to those of the *Delphinium Staphisagria.* (See *Staphisagriæ Semina.*) The flowers are bitter and acrid, and having formerly been supposed to possess the power of healing wounds, gave the name of *consolida* to the species. They were considered diuretic emmenagogue, and vermifuge; but are not now used. The seeds are very acrid, are esteemed diuretic, and in large doses produce vomiting and purging. A tincture prepared by macerating an ounce of the seeds in a pint of diluted alcohol, has been found useful in spasmodic asthma and dropsy. The dose is ten drops, to be gradually increased till some effects upon the system are evinced. The remedy has been employed both in America and England; and the seeds of an indigenous species, the *D. exaltatum*, have been applied to a similar purpose. The root probably possesses the same properties with other parts of the plant; but, though designated in the Pharmacopœia, is little if at all used. W.

◆

DIANTHI CARYOPHYLLI FLORES. *Ed.*

Flowers of the Clove Pink.

Off. Syn. DIANTHUS CARYOPHYLLUS. Flores. *Dub.*

Dianthus. *Sex. Syst.* Decandria Digynia.—*Nat. Ord.* Caryophylleæ.

Gen. Ch. *Calyx* cylindrical, one-leafed, with four scales at the base. *Petals* five, with claws. *Capsule* cylindrical, one-celled. *Willd.*

Dianthus Caryophyllus. Willd. *Sp. Plant.* ii. 674; Woodv. *Med. Bot.* p. 579. t. 205. The *clove pink* or *carnation* is too well known to require minute description. It is a perennial, herbaceous plant, characterized as a species by its branching stem; its solitary flowers; the short ovate scales of its calyx; its very broad, beardless petals; and its linear, subulate, channeled, glaucous leaves. Indigenous in Italy, it is every where cultivated in gardens for the beauty of its flowers, of which numerous varieties have been produced by horticulturists. Those are selected for medicinal use which have the deepest red colour, and the most aromatic odour. The petals should not be collected till the flower is fully blown, and should be employed in the recent state.

They have a fragrant odour said to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation.

In Europe they are employed to impart colour and flavour to a syrup which serves as a vehicle for other less pleasant medicines.

DIGITALIS. *U.S.*

Foxglove.

"Digitalis purpurea. Folia. *The leaves.*" *U.S.*

Off. Syn. DIGITALIS FOLIA et SEMINA. Digitalis purpurea. Folia et Semina. *Lond.;* DIGITALIS PURPUREÆ FOLIA. *Ed.;* DIGITALIS PURPUREA. Folia, *Dub.*

Digitale pourprée, Doightier, *Fr.;* Purpurrother Fingerhut, *Germ.;* Digitale purpurea, *Ital.;* Dedalera, *Span.*

DIGITALIS. *Sex. Syst.* Didynamia Angiospermia.—*Nat. Ord.* Scrophularineæ.

Gen. Ch. *Calyx* five-parted. *Corolla* bell-shaped, five-cleft, ventricose. *Capsule* ovate, two-celled. *Willd.*

Digitalis purpurea. Willd. *Sp. Plant.* iii. 283; Woodv. *Med. Bot.* p. 218. t. 78. Foxglove is a beautiful plant, with a biennial or perennial, fibrous root, which sends forth large tufted leaves, and a single, erect, downy, and leafy stem, rising from two to five feet in height, and terminating in an elegant spike of purple flowers. The lower leaves are ovate, pointed, about eight inches in length, and three in breadth, and stand upon short, winged footstalks; the upper are alternate, sparse, and lanceolate; both are obtusely serrated at their edges, and have wrinkled velvety surfaces, of which the upper is of a fine deep-green colour, the under paler and more downy. The flowers are numerous, and attached to the upper part of the stem by short peduncles, in such a manner as generally to hang down upon one side. At the base of each peduncle is a floral leaf, which is sessile, ovate, and pointed. The calyx is divided into five segments, of which the uppermost is narrower than the others. The corolla is monopetalous, bell-form, swelling on the lower side, irregularly divided at the margin into short obtuse lobes, and in shape and size bearing some resemblance to the end of the finger of a glove, a circumstance which has suggested most of the names by which the plant is designated in different languages. The mouth of the corolla is guarded by long, soft hairs. Its general colour is bright purple; but sometimes the flowers are whitish. The internal surface is sprinkled with black spots upon a white ground. The filaments are white, curved, and surmounted by large yellow anthers. The style, which is simple, supports a bifid stigma. The seeds are very small, numerous, of a dark colour, and contained in a pyramidal, two-celled capsule.

The foxglove grows wild in most of the temperate countries of Europe, where it flowers in the middle of summer. In this country it is cultivated both as an ornamental garden plant, and for medicinal purposes. The leaves are the part usually employed, although the London College recognises the seed also as officinal. Much care is requisite in selecting, preparing, and preserving foxglove in order to insure its activity. The leaves should be gathered in the second year, immediately before or during the period of inflorescence, and those only should be chosen which are full grown and perfectly fresh. (*Geiger.*) It is said that those plants are preferable which grow spontaneously in elevated places, exposed to the sun. (*Duncan.*) As the leaf-stalk and midrib are comparatively inactive, they may be rejected. The leaves should be dried either in the sunshine, or by a gentle heat before the fire; and care should be taken to keep them separate during the drying process. It is probably owing to the want of proper attention in preparing digitalis for the market, that it is so often found to be inefficient. Much of the medicine kept in our shops is obtained from the settlement of the Shakers in New York, and is in the state of oblong compact masses, into which the leaves are probably compressed before they are thoroughly dried; at least the cakes when opened are not unfrequently found to be somewhat mouldy. This mode of preparing the drug is highly objectionable; and it is not surprising that our practitioners are so frequently disappointed in its effects. A comparison of the sensible properties of digitalis in this state, with those of the carefully dried leaves imported from England, will at once evince the great superiority of the latter. It is, indeed, highly probable, that the wild plant in its native country attains greater medicinal perfection, than that which is cultivated in a foreign soil. The dried leaves should be kept in tin canisters, well closed so as to exclude light and moisture, or they may be pulverized, and the powder preserved in well-stopped and opaque phials.

Properties. Foxglove is without smell in the recent state, but acquires a faint narcotic odour when dried. Its taste is bitter and nauseous. The colour of the dried leaf is a dull pale green, modified by the whitish down upon the under surface; that of the powder is a fine deep green. Digitalis yields its virtues both to water and alchohol. The dried leaves, analyzed by Rein and Haase, were found to contain in 100 parts, 5.5 of a green resin, soft, viscid, soluble in alcohol, ether, and the volatile oils, and possessing the properties of a mixture of resin and fixed oil; 15.0 of gum mixed with a salt of potassa; 2.0 of superoxalate of potassa; 52.0 of lignin; 5.5 of water, with 5.0 parts lost. According to Haase, the virtues of digitalis depend upon the soft resin. (*Berzelius, Trait. de Chim.*) MM. Brault and Poggiale state, as the result of their researches, that the leaves contain chlorophylle, resin, a fatty matter, starch, vegetable fibre, gum, tannin, a volatile oil, and salts of lime and of potassa. They are disposed to ascribe the virtues of the plant chiefly to the resin, which has a bitter, acid, almost corrosive taste. The pretended *digitalin* of M. Le Royer has turned out to be nothing more than a mixture of chlorophylle, resin, fatty matter, and different salts of lime and of potassa. (*Journ. de Pharm.* xxi. 130.)

Medical Properties and Uses. Digitalis is narcotic, sedative, and diuretic. When administered in quantities sufficient to bring the system under its influence, it produces a sense of tightness or weight with dull pain in the head, vertigo, dimness or other disorder of vision, and more or less confusion in the mental operations. At the same time, it occasionally gives rise to irritation in the pharynx and œsophagus, which extends to the larynx and trachea, producing hoarseness; and in more than one instance ptyalism has been observed to result from its action. It sometimes also disturbs the bowels, and excites nausea, or even vomiting. Another effect, which, in a practical point of view, is perhaps the most important, is an augmented flow of urine. This has been ascribed by some to the increased absorption which digitalis is supposed to produce; and in support of this opinion it is stated, that its diuretic operation is observable only when dropsical effusion exists; but the fact seems to be, that it is capable of augmenting the quantity of urine in health, and it probably exerts a directly stimulating influence over the secretory function of the kidneys. This influence is said sometimes to extend to the genital organs.* Besides the various effects above detailed, most of which indicate the existence of a stimulating power, digitalis exerts a remarkably sedative operation upon the heart. This is exhibited in the reduction both of the force and frequency of the pulse, which sometimes sinks from the ordinary standard to 50, 40, or even 30 strokes in the minute. In some instances, however, it undergoes little change; in others only becomes irregular; and we are told that it is even occasionally increased in frequency. It was observed by Dr. Baildon, that the effects of digitalis upon the circulation were very much influenced by posture. Thus, in his own case, the pulse which had been reduced from 110 to 40 in the recumbent position, was increased to 72 when he sat, and to 100 when he stood. We do not discover any thing remarkable in this circumstance. It is well known that the pulse is almost always more frequent in the erect than in the horizontal posture, and the difference is greater in a state of debility than in health. Digitalis diminishes the frequency of the pulsations of the heart by a directly debilitating power; and this very debility, when any exertion is made which calls for increased action in that organ, causes it to attempt by an increase in the number of its contractions, to meet the demand which it is wholly unable to supply by an increase in their force.

The various effects above detailed may result from digitalis given in doses calculated to produce its remediate influence. In larger quantities its operation is more violent. Nausea and vomiting, stupor or delirium, cold sweats, extreme prostration of general strength, hiccough, convulsions, syncope, are among the alarming symptoms which indicate the poisonous character of the medicine. These effects are best counteracted by stimulants, such as brandy, the volatile alkali, and opium. When there is reason to believe that any of the poison remains, it is obviously proper, before employing other measures, to evacuate the stomach by the free use of warm liquids.

A peculiarity of digitalis is, that after having been given in moderate doses for several days, without any apparent effect, it sometimes acts suddenly with an accumulated influence, endangering even the life of the patient. It is, moreover, very permanent in its operation, which, having once commenced, is maintained like that of mercury, for a considerable period, without any fresh accession of the medicine. The practical inferences deducible from these properties of digitalis, are first, that after it has been administered for some time without effect, great caution should be observed not to increase the dose, nor to urge the medicine too vigorously; and secondly, that after its effects have begun to appear, it should be suspended for a time, or exhibited in moderate doses, lest a dangerous accumulation of its influence should be experienced. In numerous instances death has resulted from its incautious employment.

Digitalis has been long known to possess medicinal powers; but it was never generally used, nor regarded as a standard remedy, till after its application by Withering to the treatment of dropsy, about the year 1775. It is at present employed very extensively, both for its diuretic power, and for its sedative influence over the circulation. The former renders it highly useful in dropsical diseases, though like all other remedies it very frequently fails; the latter adapts it to the treatment of cases in which the action of the heart requires to be controlled. The idea was at one period entertained, that it might serve as a substitute for the lancet in inflammatory complaints; and it

* See an account of experiments by Professors Jœrg and others of Leipsic, in the N. Am. Med. and Surg. Journ. vol. ii. p. 235.

is at present much employed for this purpose by the Italian physicians, who practise in accordance with the *contra-stimulant* doctrine; but experience has proved that it is a very frail support in any case in which the symptoms of inflammation are such as to call for the loss of blood. As an adjuvant to the lancet, and in cases in which circumstances forbid the employment of this remedy, it is often very useful. Though it certainly has not the power, at one time ascribed to it by some practitioners, of curing phthisis, it acts beneficially as a palliative in that complaint by repressing the excited movements of the heart. In the same way it proves advantageous in aneurism, hypertrophy of the heart, palpitations from rheumatic or gouty irritation, and in various forms of hemorrhage, after action has been sufficiently reduced by the lancet. It has also been prescribed in mania, epilepsy, pertussis, and spasmodic asthma; and highly respectable testimony can be adduced in favour of its occasional efficacy in these complaints; but any good which may be derived from it is ascribable rather to its influence over the brain and nerves, than to that which it exercises over the circulation. The medicine, externally applied, is said to act speedily and powerfully as a diuretic, and to have been used advantageously in dropsy. For this purpose the fresh leaves bruised, or the tincture may be rubbed over the abdomen and on the inside of the thighs. (*Revue Mèdicale, May* 1834.)

The medicine is most effectually administered in substance. The dose of the powder is one grain, repeated twice or three times a day, and gradually increased till some effect is produced upon the head, stomach, pulse, or kidneys, when it should be omitted or reduced. The infusion and tincture are officinal preparations often resorted to. (See *Infusum Digitalis*, and *Tinctura Digitalis.*) The extract has also been employed; and Orfila found it, whether prepared with water or alcohol, more powerful than the powder; but the virtues of digitalis are too energetic to require concentration; and the preparation is not more certain than the powder. The decoction has also been used, but has nothing to recommend it.

DIOSMA CRENATA. Folia.—BUCHU. *Dub.*

Buchu Leaves.

The plant thus designated in the Dublin Pharmacopœia has been separated by Willdenow from the genus *Diosma*, and arranged with several others in a new genus, entitled *Agathosma*, which is acknowledged by other botanical writers.

AGATHOSMA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Diosmeæ.

Gen. Ch. *Calyx* five parted. *Petals* ten, unequal, inserted in the calyx. *Nectary* five-lobed, inserted in the calyx. *Loudon's Encyc.*

Agathosma crenatum. Willd. *Hort. Berol.—Diosma crenata.* Thunberg; Willd. *Sp. Plant.* i. 1138. This is a small evergreen shrub, with a stem from one to four or five feet high, the branches of which are scattered or in whorls, and bear petiolate, ovate or lanceolate, crenate, coriaceous leaves, dotted on their under surface. The flowers are white, and stand solitarily in the axils of the leaves. The fruit is a stellate capsule, containing black shining seeds. The plant is a native of the Cape of Good Hope, where, in common with others belonging to the same genus and to the analogous one of Diosma, it is called *buchu* in the language of the Hottentots, by whom the leaves are highly esteemed for their odour, and rubbed in the state of powder upon their greasy bodies.

Properties. The *buchu* leaves of the shops are from three quarters of an inch to an inch long, from three to five lines broad, elliptical, lanceolate or ovate, sometimes slightly pointed, sometimes blunt at the apex, very finely notched and glandular at the edges, smooth and of a green colour on the upper surface, dotted and paler beneath, and of a firm consistence. Their odour is strong, diffusive, and somewhat aromatic; their taste bitterish, and closely analogous to that of mint. These various properties are abundantly sufficient to distinguish them from senna, with which they might be confounded upon a careless inspection. Analyzed by Cadet de Gassicourt, they were found to contain in 1000 parts, 6.65 parts of a light, brownish-yellow volatile oil, 211.7 of gum, 51.7 of extractive, 11 of chlorophylle, and 21.51 of resin. Water and alcohol extract their virtues, which probably depend on the volatile oil and extractive matter. The latter is precipitated by the infusion of galls.

Medical Properties and Uses. Buchu leaves are gently stimulant, with a peculiar tendency to the urinary organs, producing diuresis, and, like all other similar medicines, exciting diaphoresis when circumstances favour this mode of action. The Hottentots at the Cape of Good Hope have long used them in a variety of diseases. From these rude practitioners they were borrowed by the resident English and Dutch physicians, by whose recommendation they have been recently employed to some extent in Great Britain and on the continent of Europe, and have begun to attract attention on this side of the Atlantic. They are chiefly given in complaints of the urinary organs, such as gravel, chronic catarrh of the bladder, morbid irritation of the bladder and urethra, disease of the prostate, and retention or incontinence of urine from a loss of tone in the parts concerned in its evacuation. The remedy has also been recommended in chronic rheumatism and cutaneous affections. From twenty to thirty grains of the powder may be given two or three times a day. The leaves are also used in infusion, in the proportion of an ounce to a pint of boiling water, of which the dose is one or two fluidounces. A tincture has been employed as a stimulant embrocation in local pains.

DIOSPYROS. *U.S. Secondary.*

Persimmon.

"Diospyros Virginiana. Cortex. *The bark.*" *U. S.*

Diospyros. *Sex. Syst.* Diœcia Octandria.—*Nat. Ord.* Ebenaceæ.

Gen. Ch. Male. *Calyx* four to six-cleft. *Corolla* urceolate, four to six-cleft. *Stamens* eight to sixteen; filaments often producing two anthers. Female. Flower as the male. *Stigmas* four or five. Berry eight to twelve-seeded. *Nuttall.*

Diospyros Virginiana. Willd. *Sp. Plant.* iv. 1107; Michaux, *N. Am. Sylv.* ii. 219. The persimmon is an indigenous tree, rising in the Southern States in favourable situations to the height of sixty feet, with a trunk eighteen or twenty inches in diameter; but seldom attaining more than half this size near its northren limits, and often not higher than fifteen or twenty feet.

The stem is straight, and in the old tree covered with a furrowed blackish bark. The branches are spreading; the leaves ovate; oblong, acuminate, entire, smooth, reticulately veined, alternate, and supported on pubescent footstalks. The buds are smooth. The male and female flowers are on different trees. They are lateral, axillary, solitary, nearly sessile, of a pale orange colour, and not conspicuous. The fruit is a globular berry, of a dark yellow colour externally when perfectly ripe, and containing numerous seeds embedded in a soft yellow pulp.

This tree is very common in the Middle and Southern States; but, according to Michaux, does not flourish beyond the forty-second degree of north latitude. The flowers appear in May or June; but the fruit is not ripe till the middle of autumn. While in the green state, the fruit is excessively astringent; but when perfectly mature, and after having been touched by the frost, it is sweet and palatable. We are told by Michaux, that in the Southern and Western States it is made into cakes with bran, and used for preparing beer with the addition of water, hops, and yeast. A spirituous liquor may be obtained by the distillation of the fermented infusion. The bark is the only part of the tree directed by the Pharmacopœia. It is astringent and very bitter; and is said to have been used advantageously in intermittents, and in the form of a gargle in ulcerated sorethroat. W.

DOLICHOS. *U.S.*

Cowhage.

"Dolichos pruriens. Leguminum pubes. *The bristles of the pods.*" *U. S.*

Off. Syn. DOLICHI PUBES. Dolichos pruriens. Leguminum pubes. *Lond.;* DOLICHI PRURIENTIS PUBES. Ex Legumine. *Ed.;* DOLICHOS PRURIENS. Pubes leguminis. *Dub.*

Pois a gratter, *Fr.;* Kuhkrätze, *Germ.;* Dolico Scottante, *Ital.*

Dolichos. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ.

Gen. Ch. Base of the *Banner* with two oblong parallel callosities, compressing the wings beneath. *Willd.*

The cowhage plant has been separated by some botanists from the Dolichi. De Candolle has erected the section to which it belongs into a new genus with the title *Mucuna;* and Persoon places it in the genus *Stizolobium.* All the British Pharmacopœias, as well as that of the United States, refer it to Dolichos.

Dolichos pruriens. Willd. *Sp. Plant.* iii. 1041; Woodv. *Med. Bot.* p. 422. t. 153. This is a perennial climbing plant, with an herbaceous branching stem, which twines round the trees in its vicinity, and rises to a considerable height. The leaves are ternate, and stand on long footstalks placed alternately on the stem at the distance of a foot from each other. They are smooth on their upper surface, and hairy beneath. The flowers, which resemble those of the pea in form, are large, of a red or purplish colour, usually placed in threes on short peduncles, and hang from the axils of the leaves in pendent spikes about a foot in length. The fruit is a coriaceous pod, shaped like the Italic letter *ſ*, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation. The plant is a native of the East and West Indies, and other parts of tropical Asia and America. The part usually imported is the pod, of which the hairs are the officinal portion.

Medical Properties and Uses. These spiculæ are said to be possessed of powerful vermifuge properties; and are thought to act mechanically, by penetrating the worms. That they do act in this manner is evinced, as well by the result of direct experiment upon worms out of the body, as by the fact that neither the tincture nor decoction is in the slightest degree anthelmintic. Why the worms should be injured, and the mucous membrane of the stomach and bowels escape with impunity, is not satisfactorily explained. The medicine was first employed as a vermifuge by the inhabitants of the West Indies, and thence passed into British practice. The testimony in its favour is too strong to admit of any reasonable doubt as to its efficiency. It has been chiefly employed against the round worm; but all the different species which infest the alimentary canal have been expelled by its use. It is best administered mixed with some tenacious vehicle. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistence of thick honey. The dose of this preparation is a tablespoonful for an adult, a teaspoonful for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic.

The root of the D. pruriens is said by Ainslie to be employed in the East Indies in the treatment of cholera; and both this part and the pods have been thought to possess diuretic properties. W.

◆

DRACONTIUM. *U.S. Secondary.*

Skunk Cabbage.

"Dracontium fœtidum, *Willd.* Ictodes fœtidus, *Bigelow.* Symplocarpus fœtidus, *Barton.* Radix. *The Root.*" *U. S.*

Botanists have had some difficulty in properly arranging this plant. It is attached by Willdenow to the genus *Dracontium*, by Michaux and Pursh is considered a *Pothos*, and by American botanists has been erected into a new genus, which Nuttall calls *Symplocarpus* after Salisbury, and for which Dr. Bigelow has proposed the name *Ictodes*, expressive of the odour of the plant. The term *Symplocarpus*, though erroneous in its origin, was first proposed for the new genus, and, having been adopted by several botanists, should be retained.

SYMPLOCARPUS. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Adroideæ.

Gen. Ch. *Spathe* hooded. *Spadix* covered with perfect flowers. *Calyx* with four segments. *Petals* none. *Style* pyramidal. *Seeds* immersed in the spadix. *Bigelow.*

Symplocarpus fœtidus. Barton, *Med. Bot.* i.123.—*Ictodes fœtidus.* Bigelow, *Am. Med. Bot.* ii. 41. The *skunk cabbage* is a very curious plant, the only one of the genus to which it belongs. The root is perennial, large, abrupt, and furnished with numerous fleshy fibres, which penetrate to the depth of two feet or more. The spathe, which appears before the leaves, is ovate, acuminate, obliquely depressed at the apex, auriculated at the base, folded inwards at the edges, and of a brownish-purple colour, varied with spots of red, yellow, and green. Within the spathe, the flowers, which resemble it in colour, are placed in great numbers upon a globose, peduncled spadix, for which they form a compact covering. After the spathe has decayed, the spadix continues to grow, and when the fruit is mature, has attained a size exceeding by several fold its original dimensions. The different parts of the flower, with the exception of the anthers, augment in like proportion. At the base of each style is a roundish seed, immersed in the spadix, about the size of a pea, and speckled with purple and yellow. The leaves, which rise from the ground after the flowers, are numerous and crowded, oblong, cordate, acute, smooth, strongly veined, and attached to the root by long petioles, which are hollowed in front, and furnished with coloured sheathing stipules. At the beginning of May, when the leaves are fully developed, they are very large, being from one to two feet in length, and from nine inches to a foot in breadth.

This plant is indigenous, growing abundantly in meadows, swamps, and other wet places, throughout the whole northern and middle sections of the Union. Its flowers appear in March and April, and in the lower latitudes often so early as February. The fruit is usually quite ripe, and the leaves decayed before the end of August. The plant is very conspicuous from its abundance, and from the magnitude of its leaves. All parts of it have a disagreeable fetid odour, thought to resemble that of the offensive animal after which it is named. This odour resides in an extremely volatile principle, which is rapidly dissipated by heat, and diminished by desiccation. The root is the part usually employed in medicine. It should be collected in autumn, or early in spring, and dried with care.

The dried root, as found in the shops, consists of two distinct portions; the body or caudex, either whole or in transverse slices, and the separated radicles. The former, when whole, is cylindrical, or in the shape of a truncated cone, two or three inches long by about an inch in thickness, externally dark brown and very rough from the insertion of the radicles, internally white and amylaceous. The latter are in pieces of various lengths, about as thick as a hen's quill, very much flattened and wrinkled, white within, and covered by a yellowish reddish-brown epidermis, of a considerably lighter shade than that of the body of the root. The fetid odour remains, to a greater or less extent, for a considerable period after the completion of the drying process. The taste, though less decided than in the fresh state, is still acrid, manifesting itself after the root has been chewed for a short time, by a prickling and smarting sensation in the mouth and throat. The acrimony, however, is dissipated by heat, and is entirely lost in decoction. It is also diminished by time and exposure; and the root should not be kept for use longer than a single season.

Medical Properties and Uses. The properties of this root are those of a stimulant, antispasmodic, and narcotic. In large doses it occasions nausea and vomiting, with headach, vertigo, and dimness of vision. Dr. Bigelow has witnessed these effects from thirty grains of the recently dried root. The medicine was introduced into notice by the Rev. Dr. Cutler, who recommended it highly as an antispasmodic in asthma, and it has been subsequently employed with apparent advantage in chronic catarrh, chronic rheumatism, and hysteria. Cures are also said to have been effected by its use in dropsy.

It is best given in powder, of which the dose is from ten to twenty grains, to be repeated three or four times a day, and gradually increased till some evidence of its action is afforded. A strong infusion is sometimes employed, and the people in the country prepare a syrup from the fresh root; but the latter preparation is very unequal. The root itself, as kept in the shops, is of uncertain strength, in consequence of its deterioration by age. W.

DULCAMARA. *U.S.*

Bittersweet.

"Solanum dulcamara. Caulis. *The stalk.*" *U.S.*

Off. Syn. DULCAMARÆ CAULIS. Solanum Dulcamara. Caulis. *Lond.;* SOLANI DULCAMARÆ CAULES, *Ed.;* DULCAMARA. SOLANUM DULCAMARA. Caules. *Dub.*

Douce-amère, *Fr.:* Bittersüss, Alpranken, *Germ.;* Dulcamara, *Ital., Span.*

SOLANUM. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ.

Gen. Ch. *Corolla* wheel-shaped. *Anthers* somewhat coalescing, opening by two pores at the apex. *Berry* two-celled. *Willd.*

This genus includes numerous species, of which several have been used in medicine. Besides the *S. Dulcamara*, which is the only officinal species, two others merit a brief notice. 1. The *Solanum nigrum*, the *common garden*, or *black nightshade*, is an annual plant from one to two feet high, with an unarmed herbaceous stem, ovate, angular-dentate leaves, and white or pale violet flowers, arranged in peduncled nodding umbel-like racemes, and followed by clusters of spherical black berries, about the size of peas. There are numerous varieties of this species, one of which is a native of the United States. The leaves are the part employed in medicine. They are said to produce diaphoresis, sometimes diuresis and moderate purging, and in large doses nausea and giddiness. As a medicine they have been used in cancerous, scrofulous, and scorbutic diseases, and other painful ulcerous affections, being given internally, and applied at the same time in the form of poultice, ointment, or decoction to the tumours or ulcers themselves. A grain of the dried leaves may be given every night and gradually increased to ten or twelve grains, or till some sensible effect is experienced. The medicine, however, is scarcely used at present. By some persons the poisonous properties usually ascribed to the common nightshade are doubted. M. Dunal of Montpelier states as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon as food, having been previously boiled in water. In the latter case, the active principle of the plant must have been extracted by decoction. 2. The *Solanum tuberosum* or *common potato* is interesting on account of the nutritive properties of its tubers, so extensively employed as food. The leaves, stalks, and unripe berries are asserted to have narcotic properties, and an extract prepared from the leaves has been employed as a remedy in cough and spasmodic affections, in which it is said to act like opium. (*Geiger.*) From half a grain to two grains may be given as a dose. Dr. Latham of London found the extract to produce very favourable effects in various chronic complaints, such as protracted cough, chronic rheumatism, angina pectoris, cancer of the uterus, &c. The influence which it exercised upon the nervous system was strongly marked, and, in many instances, the dose could not be increased above a few grains without giving rise to threatening symptoms. It appeared to Dr. Latham to be very analogous in its operation to digitalis. His experiments were repeated in Philadelphia by Dr. Worsham with very different results. The extract was found in the quantity of nearly one hundred grains to produce no sensible effect on the system. (*Philad. Journ. of Med. and Phys. Sciences*, vi. 22.) We can reconcile these opposite statements only upon the supposition that the properties of the plant vary with the season, or with the place and circumstances of culture. An excellent form of starch, called potato arrow-root, is prepared from potatoes for medical use; and an imitation of sago is also made from them in Germany. Dr. Julius Otto found *solania* in the germs of the potato. He was induced to make the investigation by observing, that cattle were destroyed by feeding on the residue of germinated potatoes, used for the manufacture of brandy. (See *Journ. of Phil. Col. of Pharm.* vi. 348.)

Solanum Dulcamara. Willd. *Sp. Plant.* i. 1028; Woodv. *Med. Bot.* p. 237. t. 84; Bigelow, *Am. Med. Bot.* i. 169. The *bittersweet* or *woody nightshade* is a climbing shrub, with a slender, roundish, branching, woody stem, which, in favourable situations, rises six or eight feet in height. The leaves are alternate, petiolate, ovate, pointed, veined, soft, smooth, and of a dull green colour. Many near the top of the stem are furnished with lateral projections at their base, giving them a hastate form. Most of them are quite entire, some cordate at the base. The flowers are disposed in elegant clusters, somewhat analogous to cymes, and standing opposite to the leaves. The calyx is very small, purplish, and divided into five blunt persistent segments. The corolla is wheel-shaped, with five pointed reflected segments, which are of a voilet-blue colour, with a darker purple vein running longitudinally through their centre, and two shining greenish spots at the base of each. The filaments are very short, and support large erect lemon-yellow anthers, which cohere in the form of a cone around the style. The berries are of an oval shape and a bright scarlet colour, and continue to hang in beautiful bunches after the leaves have fallen.

This plant is common to Europe and North America. It flourishes most luxuriantly in damp and sheltered places, as on the banks of rivulets, and among the thickets which border our natural meadows. It is also found in higher and more exposed situations, and is frequently cultivated in gardens. In the United States it extends from New England to Ohio, and is in bloom from June to August. The root and stalk are possessed of the medicinal properties of the plant, though the latter only is officinal. The berries, which were formerly esteemed poisonous, and thought to act with great severity on the stomach and bowels, are now said to be innoxious. Bittersweet should be gathered in autumn, after the fall of the leaf; and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

The dried twigs, as brought to the shops, are of various lengths, cylindrical, about as thick as a goose-quill, externally wrinkled and of a grayish-ash colour, consisting of a thin bark, an interior ligneous portion, and a central pith. They are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous smell. Their taste, which is at first bitter, and afterwards sweetish, has given origin to the name of the plant. Boiling water extracts all their virtues. These are supposed to depend, at least in part, upon a peculiar alkaline principle called *solanin* or *solania*, which was originally discovered by M. Desfosses of Besançon in the berries of the *Solanum nigrum*, and has subsequently been found in the stalks, leaves, and berries of the *S. Dulcamara* and *S. tuberosum*. It is supposed to exist in the bittersweet combined with malic acid. It is obtained by precipitating the decoction of bittersweet with ammonia or magnesia, washing the precipitate with cold water, and then treating it with boiling alcohol, which deposites the alkaline principle on cooling, and still further by evaporation. Solania is in the form of a white opaque powder, inodorous, of a bitter taste, fusible at a little above 212°, scarcely soluble in water, soluble in alcohol and ether, and capable of neutralizing the acids. Given to a cat it was found by M. Desfosses to operate at first as an emetic, and afterwards as a narcotic. Dr. J. Otto observed, among its most striking effects, a paralytic condition of the posterior limbs of the animals to which it was administered. One grain of the sulphate of solania was sufficient in his hands to destroy a rabbit in six hours. Besides solania, the stalks of the S. Dulcamara contain, according to Pfaff, a peculiar principle to which he has given the name of *picroglycion*, indicative of the taste at once bitter and sweet which it is said to possess. This has been obtained in a crystalline state by Biltz, by the following process. The watery extract is treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with subacetate of lead, the excess of this salt decomposed by sulphuretted hydrogen, the liquor then evaporated to dryness, and the residue treated with acetic ether, which yields the principle in the form of small isolated crystals by spontaneous evaporation.

Medical Properties and Uses. Dulcamara possesses narcotic properties, with the power of increasing the secretions, particularly that of the kidneys and skin. Its narcotic effects do not become obvious, unless when it is taken in large quantities. In overdoses it produces nausea, vomiting, faintness, vertigo, and convulsive muscular movements. It has been recommended in various diseases, but is now nearly confined to the treatment of cutaneous eruptions, particularly those of a scaly character, as lepra, psoriasis, and ptyriasis. In these complaints it is often decidedly beneficial, especially in combination with minute doses of the antimonials. Its influence upon the secretions is insufficient to account for its favourable effects, and we must be content with ascribing them to an alterative action. It is said to have been beneficially employed in chronic rheumatism. Antaphrodisiac properties are ascribed to it by some physicians. (See *Am. Cyc.* of *Pract. Med.* ii. 23.) The usual form of administration is that of decoction, of which two fluidounces may be taken four times a day, and gradually increased till some slight disorder of the head indicates the activity of the medicine. (See *Decoctum Dulcamaræ.*) An extract may also be prepared, of which the dose is from five to ten grains. That of the powder would be from thirty grains to a drachm.

In cutaneous affections a strong decoction is often applied to the skin, at the same time that the medicine is taken internally.

ELATERIUM. *U.S.*

Elaterium.

"Momordica elaterium. Materia fructûs succo demissa. *The substance deposited by the juice of the fruit.*" *U.S.*

Off. Syn. ELATERII PEPONES. Momordica Elaterium. Pepones recentes.—EXTRACTUM ELATERII. *Lond.;* ELATERIUM. Ex Momordicâ Elaterio. *Ed.;* MOMORDICA ELATERIUM. Fructus. Fæcula. Folia.—ELATERIUM.—EXTRACTUM ELATERII. *Dub.*

Elaterion, *Fr.;* Elaterium, *Germ.;* Elaterio, *Ital.*, *Span.*

MOMORDICA. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Cucurbitaceæ.

Gen. Ch. MALE. *Calyx* five-cleft. *Corolla* five-parted. *Filaments* three. FEMALE. *Calyx* five-cleft. *Corolla* five-parted. *Style* trifid. *Gourd* bursting elastically. *Willd.*

Momordica Elaterium. Willd. *Sp. Plant.* iv. 605; Woodv. *Med. Bot.* p. 192. t. 72. The *wild* or *squirting cucumber* is a perennial plant, with a large fleshy root, from which proceed several round, thick, rough stems, branching and trailing like the common cucumber, but without tendrils. The leaves are petiolate, large, rough, irregularly cordate, and of a grayish-green colour. The flowers are yellow, and proceed from the axils of the leaves. The fruit has the shape of a small oval cucumber, about an inch and a half long, an inch thick, of a greenish or grayish colour, and covered with stiff hairs or prickles. When fully ripe, it separates from the peduncle, and throws out its juice and seed with considerable force through an opening at the base, where it was attached to the footstalk. The name of squirting cucumber was derived from this circumstance, and the scientific and officinal title is supposed to have had a similar origin, though some authors maintain that the term *elaterium* was applied to the medicine, rather from the mode of its operation upon the bowels, than from the projectile property of the fruit.*

This species of Momordica is a native of the South of Europe; and is cultivated in Great Britain, where, however, it perishes in the winter. Elaterium is the substance spontaneously deposited by the juice of the fruit, when separated, and allowed to stand. Dr. Clutterbuck of London has proved that it is contained only in the free juice which surrounds the seeds, and which is obtained without expression. The body of the fruit itself, the seeds, as well as other parts of the plant, are nearly or quite inert. When the fruit is sliced and placed upon a sieve, a perfectly limpid and colourless juice flows out, which after a short time becomes turbid, and in the course of a few hours begins to deposite a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white colour, slightly tinged with green. It is the genuine elaterium, and was found by Clutterbuck to purge violently in the dose of one-eighth of a grain. But the quantity contained in the fruit is exceedingly small. Clutterbuck obtained only six grains from forty cucumbers. Commercial elaterium is a much weaker medicine, owing in part, perhaps, to adulteration, but much more to the mode in which it is prepared. In order to increase the product, the juice of the fruit is often expressed; and there is reason to believe that it is sometimes evaporated so as to form an extract, instead of being allowed to deposite the active matter. The French elaterium is prepared by expressing the juice, clarifying it by rest and filtration, and then evaporating it to a suitable consistence. As the liquid which remains after the deposition of the sediment is comparatively inert, it will be readily perceived that the preparation of the French Codex must be very feeble. The following are the directions of the London College, with which those of the Dublin College essentially correspond. "Slice ripe wild cucumbers, express the juice very gently, and pass it through a very fine hair sieve into a glass vessel; then set it aside for some hours until the thicker part has subsided. Reject the thinner, supernatant part, and dry the thicker part with a gentle heat." The product thus obtained is less pure than the elaterium of Clutterbuck; but is probably the preparation usually imported from England. It is incorrectly denominated by the London and Dublin Colleges *Extractum Elaterii*, as it is neither an extract, strictly speaking, nor an inspissated juice. In the Pharmacopœias of the United States and Edinburgh, it is named simply *Elaterium.*

---

* From the Greek ελαυνω I drive, or ελατηϱ driver. The word elaterium was used by Hippocrates to signify any active purge. Dioscorides applied it to the medicine of which we are treating.

As the plant is not cultivated in this country for medicinal purposes, our Pharmacopœia very properly adopts as officinal, the medicine as it is found in commerce.

Properties. The elaterium of the shops is in thin flat cakes or fragments, often bearing the impression of the muslin upon which it was dried, of a greenish-gray colour, and a bitter, somewhat acrid taste. When good, it is light, pulverulent, and inflammable. As it is exceedingly variable in strength, in consequence either of adulteration or improper preparation, it is an object of some importance to ascertain in what principle its virtues reside, and to discover a mode of isolating that principle. Dr. Paris found that the alcoholic extract, treated with boiling distilled water, and afterwards dried, had the property of purging in very minute doses, while the remaining portion of the elaterium was inactive. Supposing this substance to be the active ingredient, he gave it the name of *elatin;* but from the very minute quantity of elaterium upon which he operated, his results are by no means satisfactory. The more recent experiments of Mr. Hennel of London and Mr. Morries of Edinburgh, have demonstrated the existence of a crystallizable matter in elaterium, which will probably be found to be the purgative principle; and the elatin of Dr. Paris, to be a mixture of this substance and chlorophylle, or the green colouring matter of vegetables.* Mr. Morries has proposed for the newly discovered principle the appropriate name of *elaterin.* From the analysis of Mr. Hennel, it appears that 100 parts of elaterium contain 44 of the crystallizable substance (elaterin), 17 of a green resin, 6 of starch, 27 of woody fibre, and 6 of saline matters. But the analysis cannot be considered as complete.†

Elaterin, according to Mr. Morries, crystallizes when pure in colourless microscopic rhombic prisms, which have a silky appearance when in mass. It is extremely bitter and rather styptic to the taste, insoluble in water and alkaline solutions, soluble in alcohol, ether, and hot olive oil, and sparingly soluble in dilute acids. At a temperature between 300° and 400° it melts, and at a higher temperature is dissipated in thick, whitish, pungent vapour, having an ammoniacal odour. It has no alkaline reaction. Mr. Morries procures it by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into boiling distilled water. A copious white precipitate immediately forms, and increases as the liquor cools. This, when separated and well washed with distilled water, is the elaterin sufficiently pure for medical use. It may be rendered quite pure by dissolving in alcohol, evaporating, and precipitating as before. Mr. Hennel obtained it by treating with ether the alcoholic extract procured by the spontaneous evaporation of the tincture. This consists of elaterin and the green resin, the latter of which being much more soluble in ether than the former, is completely extracted by this fluid, leaving the elaterin pure. But as elaterin is also slightly soluble in ether, a portion of this principle is wasted by Mr. Hennel's method. By evaporating the ethereal solution, the green resin is obtained in a separate state. Mr. Hennel states that this was found to possess the purgative property of the elaterium in a concentrated state, as it acted powerfully in a dose less than one-third of a grain. But this effect was probably owing to the presence of a portion of elaterin which had been dissolved by the ether. The late Dr. Duncan of Edinburgh ascertained that the crystalline principle or elaterin, which was not tried by Mr. Hennel, produced, in the quantity of $\frac{1}{12}$th or $\frac{1}{16}$th of a grain, all the effects of a dose of elaterium. The quantity of elaterin varies exceedingly in different parcels of the drug. Mr. Morries obtained 26 per cent. from the best British elaterium, 15 per cent. from the worst, and only 5 or 6 per cent. from the French; while a portion procured according to the directions of the London College, yielded to Mr. Hennel upwards of 40 per cent. This great diversity in the strength of the elaterium renders the substitution of its purgative principle highly desirable.

---

* The substance to which Pelletier gave the name of *chlorophylle*, under the impression that it was a peculiar proximate principle, has been ascertained by that chemist to be a mixture of wax, and a green fixed oil. *Journ. de Pharm.* xix. 109.

† See a paper by Mr. Henry Hennel in the Journal of the Royal Institution of Great Britain, May 1831; also a paper by Mr. John D. Morries in the Ed. Med. and Surg. Journ. April 1831.

Medical Properties and Uses. Elaterium is a powerful hydragogue cathartic, and in the full dose generally excites nausea and vomiting. If too freely administered, it operates with great violence both upon the stomach and bowels, producing inflammation of these organs, which has in some instances eventuated fatally. It also increases the flow of urine. The fruit was employed by the ancients, and is recommended in the writings of Dioscorides as a remedy in mania and melancholy. Sydenham and his cotemporaries considered elaterium highly useful in dropsy; but, in consequence of some fatal results from its incautious employment, it fell into disrepute, and was generally neglected, till again brought into notice by Dr. Ferriar. It is now considered one of the most efficient hydragogue cathartics in the treatment of dropsical diseases, in which it has sometimes proved successful after all other remedies have failed. The full dose of the commercial elaterium is from one to two grains; but as in this quantity it generally vomits, if of ordinary strength, the best mode of administering it is in the dose of half a grain repeated every hour till it operates. The dose of Clutterbuck's elaterium is $\frac{1}{8}$th of a grain. That of elaterin is from $\frac{1}{16}$th to $\frac{1}{12}$th of a grain, and is best given in solution. One grain may be dissolved in a fluidounce of alcohol with four drops of nitric acid, and from 30 to 40 minims may be given diluted with water. W.

ELEMI. *Lond., Dub.*

Elemi.

"Amyris elemifera. *Resina.*" *Lond., Dub.*

Résine élémi, *Fr.;* Oelbaumharz, Elemi, *Germ.;* Elemi, *Ital.;* Goma de limon, *Span.*

AMYRIS. *Sex. Syst.* Octandria Monogynia.—*Nat. Ord.* Terebintaceæ, *Juss.;* Amyrideæ, *R. Brown, Lindley.*

Gen. Ch. Calyx four-toothed. *Petals* four, oblong. *Stigma* four-cornered. *Berry* drupaceous. *Willd.*

Some botanists separate from this genus the species which have their fruit in the form of a capsule instead of a nut, and associate them together in a distinct genus with the name of *Icica.* This is recognised by De Candolle.

Most of the trees belonging to these two genera yield, when wounded, a resinous juice analogous to the turpentines, and differing little as procured from the different species. It is not improbable that the drug usually known by the name of *elemi*, though referred by the Colleges to one tree, is in fact derived from several. That known to the ancients is said to have been obtained from Ethiopia, and all the elemi of commerce was originally brought from the Levant. The tree which afforded it was not accurately known, but was supposed to be a species of Amyris. Geiger states, that it was derived from the A. Zeilanica, growing in Ceylon. At present the drug is taken to Europe from Brazil, and is believed to be the product of a plant mentioned by Marcgrav under the name of *icicariba*, and considered by Linnæus as the *Amyris elemifera*. It appears, however, to be properly an *Icica*, and De Candolle denominates it *I. Icicariba*. We can find no detailed description of the tree. It has a lofty trunk, with pinnate leaves, consisting of three or five pointed, perforated leaflets, which are smooth on their upper surface, and woolly beneath. It is erroneously stated in some works to be a native of Carolina. The elemi is obtained by incisions into the tree, through which the juice flows and concretes upon the bark.

It is in masses of various consistence, sometimes solid and heavy, like wax, sometimes light and porous; unctuous to the touch; diaphanous; of diversified colours, generally greenish with intermingled points of white or yellow, sometimes greenish-white with brown stains, sometimes yellow like sulphur; fragile and friable when cold; softening by the heat of the hand; of a terebinthinate somewhat aromatic odour, diminishing with age, and said, in some varieties, to resemble that of fennel; of a warm, slightly bitter, disagreeable taste; entirely soluble, with the exception of impurities, in boiling alcohol; and affording a volatile oil by distillation. It consists, according to M. Bonastre, of 60 parts of resin, 24 of a resinous matter soluble in boiling alcohol, but deposited when the liquid cools, 12.5 of volatile oil, 2 of extractive, and 1.5 of acid and impurities. It is sometimes adulterated with colophony and turpentine.

Medical Properties and Uses. Elemi has properties analogous to those of the turpentines; but is exclusively applied to external use. In the United States it is rarely employed even in this way. In the pharmacy of Europe it enters into the composition of numerous plasters and ointments. We are told that it is occasionally brought to this country in small fragments mixed with the coarser kinds of gum Arabic from the Levant and India.

ERIGERON CANADENSE. *U.S. Secondary.*

Canada Fleabane.

"Erigeron Canadense. Planta. *The plant.*" *U.S.*

ERIGERON. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. Calyx imbricated, sub-hemispherical, in fruit often reflected. *Florets of the ray* linear, very narrow, numerous. *Receptacle* naked. *Pappus* double, exterior minute, interior pilose, of few rays. *Nuttall.*

Erigeron Canadense. Willd. *Sp. Plant.* iii. 1954. This is an indigenous annual plant, with a stem from two to six feet high, covered with stiff hairs, and divided into numerous branches. The leaves are linear lanceolate, and edged with hairs; those at the root are dentate. The flowers are very small, numerous, white, and arranged in terminal panicles. They differ from those of the other species of Erigeron in having an oblong calyx, the rays very minute and more numerous than the florets of the disk, and the seed-down simple. Hence by some botanists the plant is placed in a sub-genus with the title *Cænotus*. Another variety of the *E. Canadense*, which Mr. Nuttall makes a distinct species, with the title *E. pusilum*, is not more than from four to six inches high, and has an erect smooth stem, less branched than the preceding, with all its leaves entire, and scabrous on the margin. The panicle is simple, and the peduncles filiform, nearly naked, divaricate, each bearing two or three flowers.

The Canada fleabane is very common throughout the northern and middle sections of the United States, and has become naturalized in many parts of Europe. It abounds in neglected fields, and blooms in July and August. The plant, all parts of which are medicinal, should be collected while in flower. The leaves and flowers are said to possess its peculiar virtues in greatest perfection.

This species of Erigeron has an agreeable odour, and a bitterish, acrid, somewhat astringent taste. Among its constituents, according to Dr. De Puy, are bitter extractive, tannin, gallic acid, and volatile oil. Both alcohol and water extract its virtues. Its acrimony is diminished by decoction, probably in consequence of the escape of the oil.

Medical Properties and Uses. From the observations of Dr. De Puy, it appears to be diuretic, tonic, and astringent; and has been found useful in dropsical complaints and diarrhœa. It may be given in substance, infusion, tincture, or extract. The dose of the powder is from thirty grains to a drachm; of an infusion prepared in the proportion of an ounce of the plant to a pint of boiling water, from two to four fluidounces; of the aqueous extract from five to ten grains. In each case the dose should be repeated every two or three hours. W.

ERIGERON HETEROPHYLLUM. *U.S. Secondary.*

Various-leaved Fleabane.

"Erigeron heterophyllum. Planta. *The Plant.*" *U.S.*

ERIGERON PHILADELPHICUM. *U.S. Secondary.*

Philadelphia Fleabane.

"Erigeron Philadelphicum. Planta. *The Plant.*" *U.S.*

Erigeron. See ERIGERON CANADENSE.

1. *Erigeron heterophyllum.* Willd. *Sp. Plant.* iii. 1956; Barton, *Am. Med. Bot.* i. 231. This is a biennial herbaceous plant, belonging both to North America and Europe. It has a branching root, from which proceed several erect, roundish, striated, pubescent stems, much divided near the top, and rising two or three feet in height. The lower leaves are ovate, acute, deeply toothed, and supported upon long winged footstalks; the upper are lanceolate, acute, deeply serrate in the middle, and sessile; the floral leaves are lanceolate and entire; all, except those from the root, are ciliate at the base. The flowers are in terminal corymbs. The florets of the disk are yellow, those of the ray numerous, very slender, and of a white, pale blue, or pale purple colour. The flowering period is from June to October.

Erigeron Philadelphicum. Willd. *Sp. Plant.* iii. 1957; Barton, *Med. Bot.* i. 227. The Philadelphia fleabane is perennial and herbaceous, with a branching yellowish root, and from one to five erect stems, which rise two or three feet in height, and are much branched at top. The whole plant is pubescent. The lower leaves are ovate lanceolate, nearly obtuse, ciliate on the margin, entire or marked with a few serratures, and supported on very long footstalks; the upper are narrow, oblong, somewhat wedge-shaped, obtuse, entire, sessile, and slightly embrace the stem; the floral leaves are small and lanceolate. The flowers are numerous, radiate, and disposed in a panicled corymb, with long peduncles bearing from one to three flowers. They resemble those of the preceding species in colour, and make their appearance at about the same period.

We include these two species under one head, because they grow together, possess identical medical properties, and are indiscriminately employed. They are found in various parts of the United States, and abound in the fields about Philadelphia, where they are known and used under the common though inaccurate name of *scabious*. The whole herb is used, and should be collected while the plants are in flower. It has an aromatic odour, and a slightly bitterish taste; and imparts its properties to boiling water.

Medical Properties and Uses. Fleabane is diuretic, without being offensive to the stomach. It is a favourite remedy with some highly respectable practitioners of Philadelphia in gravel and other nephritic diseases, and has been employed with advantage in dropsy. By the late Dr. Wistar it was recommended in hydrothorax complicated with gout. When the obstinate character and long continuance of certain dropsical affections are considered, the advantage must appear obvious, of having numerous remedies calculated to mitigate the symptoms without exhausting the strength of the patient; so that when one has lost its power from repetition, we may appeal to another with some prospect of benefit. On this account it is, that fleabane is worthy the notice of the profession. It cannot be relied on for the cure of dropsy.

It is most conveniently administered in infusion or decoction, of which a pint, containing the virtues of an ounce of the herb, may be given in twenty-four hours.

W.

ERYNGIUM. *U.S. Secondary.*

Button Snakeroot.

"Eryngium aquaticum. Radix. *The root.*" *U.S.*

Eryngium. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. Flowers capitate. *Involucrum* many-leaved. Proper *Calyx* five-parted, superior, persistent. *Corolla* of five petals. *Receptacle* foliaceous, segments acute or cuspidate. *Fruit* bipartile. *Nuttall.*

Eryngium aquaticum. Willd. *Sp. Plant.* i. 1357. The *button snakeroot* or *water eryngo* is an indigenous herbaceous plant, with a perennial tuberous root, and a stem two or three feet high, sometimes, according to Pursh, six feet, generally branching by forks, but trichotomous above. The leaves are very long, linear-lanceolate on the upper part of the stem, sword-shaped below, with bristly spines at distant intervals upon their margin. The floral leaves are lanceolate and dentate. The flowers are white or pale, and disposed in globose heads, with the leaflets of the involucrum shorter than the head, and, like the scales of the receptacle, entire. This plant is found in low wet places, from Virginia to Carolina. Its period of flowering is August.

The root, which is the medicinal portion, has a bitter, pungent, aromatic taste, provoking, when chewed, a flow of saliva. It is diaphoretic, expectorant, in large doses occasionally emetic; and is used by some physicians in decoction as a substitute for seneka. (*Bigelow.*) We are told in Barton's "Collections," that it is nearly allied to the contrayerva of the shops. W.

ERYTHRONIUM. *U.S. Secondary.*

Erythronium.

"Erythronium Americanum. Planta. *The Plant.*" *U.S.*

ERYTHRONIUM. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Liliaceæ.

Gen. Ch. Calyx none. *Corolla* inferior, six-petalled; the three inner petals with a callous prominence on each edge near the base. *Bigelow.*

Erythronium Americanum. Muhl. *Catalogue* 84; Bigelow, *Am. Med. Bot.* iii. 151.—*E. lanceolatum.* Pursh, p. 230. This is an indigenous perennial bulbous plant, sometimes called, after the European species, *dog's tooth violet.* The bulb, which is brown externally, white and solid within, sends up a single naked slender flower-stem, and two smooth lanceolate nearly equal leaves, sheathing at their base, with an obtuse callous point, and of a brownish-green colour diversified by numerous irregular spots. The flower is solitary, nodding, yellow, with oblong lanceolate petals obtuse at the point, a club-shaped undivided style, and a three-lobed stigma.

The Erythronium grows in woods and other shady places throughout the Northern and Middle States. It flowers in the latter part of April or early in May. All parts of it are active.

In the dose of twenty or thirty grains, the recent bulb acts as an emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying. So far as we are at present acquainted with its virtues, it may be considered a useless addition to the Materia Medica. Having, however, been adopted in the original edition of the Pharmacopœia, it was deemed best, upon the revision of that work, not to expunge it from the catalogue till it had undergone a longer period of trial. W.

EUPATORIUM PERFOLIATUM. *U.S.*

Thoroughwort.

"Eupatorium perfoliatum. Herba. *The herb.*" *U. S.*

EUPATORIUM. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ Corymbiferæ.

Gen. Ch. Calyx simple or imbricate, oblong. *Style* long, and semi-bifid. *Receptacle* naked. *Pappus* pilose, or more commonly scabrous. *Seed* smooth and glandular, quinquestriate. *Nuttall.*

Of this numerous genus, comprising not less than thirty species within the limits of the United States, most of which probably possess analogous medical properties, three have found a place in the Pharmacopœia of the United States—the *E. perfoliatum*, *E. teucrifolium*, and *E. purpureum*—the first in the primary, the last two in the secondary list. The *E. cannabinum* of Europe, the root of which was formerly used as a purgative; and the *E. Aya-pana* of Brazil, the leaves of which at one time enjoyed a very high reputation as a remedy in numerous diseases, have fallen into entire neglect. The *Aya-pana* is an aromatic bitter, with the medical properties of the *E. perfoliatum* in an inferior degree.

Eupatorium perfoliatum. Willd. *Sp. Plant.* iii. 1761; Bigelow, *Am. Med. Bot.* i. 33; Barton, *Med. Bot.* ii. 125. The *thoroughwort*, or, as it is perhaps more frequently called, *boneset*, is an indigenous perennial plant, with numerous herbaceous stems, which are erect, round, hairy, from two to five feet high, simple below, and trichotomously branched near the summit. The character of the leaves is peculiar, and serves to distinguish the species at the first glance. They may be considered either as perforated by the stem, *perfoliate*, or as consisting each of two leaves joined at the base, *connate.* Considered in the latter point of view, they are opposite and in pairs, which decussate each other at regular distances upon the stem; in other words, the direction of each pair is at right angles with that of the pair immediately above or beneath it. They are narrow in proportion to their length, broadest at the base where they coalesce, gradually tapering to a point, serrate, much wrinkled, paler on the under than the upper surface, and beset with whitish hairs which give them a grayish-green colour. The uppermost pairs are sessile, not joined at the base. The flowers are white, numerous, supported on hairy peduncles, in dense corymbs, which form a flattened summit to the plant. The calyx, which is cylindrical and composed of imbricated, lanceolate, hairy scales, encloses from twelve to fifteen tubular florets, having their border divided into five spreading segments. The anthers are five in number, black, and united into a tube, through which the bifid filiform style projects above the flower.

This species of Eupatorium inhabits meadows, the banks of streams, and other moist places, growing generally in bunches, and abounding in almost all parts of the United States. It flowers from the middle of summer to the latter end of October. All parts of it are active; but the herb only is officinal.

It has a faint odour, and a strongly bitter somewhat peculiar taste. The bitterness and probably the medical virtues of the plant reside in an extractive matter, which is readily taken up by water or alcohol. No accurate analysis of thoroughwort has been made since the recent improvements in vegetable chemistry,

Medical Properties and Uses. Thoroughwort is tonic, diaphoretic, and in large doses emetic and aperient. It is said to have been employed by the Indians in intermittent fever, and has proved successful in the cure of the same complaint in the hands of several regular practitioners. The general experience, however, is not in its favour. We have seen it effectual in arresting intermittents when given freely in warm decoction, immediately before the expected recurrence of the paroxysm; but it operated in this instance by its emetic rather than its tonic power. The medicine has also been used as a tonic and diaphoretic in remittent and typhoid fevers, and is said to have been productive of advantage in yellow fever. Given in warm infusion, so as to produce vomiting or copious perspiration, in the commencement of catarrh, it will frequently arrest that complaint. It has even been recommended as a diaphoretic in inflammatory rheumatism; and may prove serviceable if administered in the absence of general arterial excitement. As a tonic it has been given with advantage in dyspepsia, general debility, and other cases in which the simple bitters are employed.

With a view to its tonic effect, it is best administered in substance, or in cold infusion. The dose of the powder is twenty or thirty grains, that of the infusion a fluidounce, frequently repeated. (See *Infusum Eupatorii*

Perfoliati.) When the diaphoretic operation is required in addition to the tonic, the infusion should be administered warm, and the patient remain covered in bed. As an emetic and cathartic, a strong decoction, prepared by boiling an ounce with three half pints of water to a pint, may be given in doses of one or two gills, or more.

Off. Prep. Infusum Eupatorii Perfoliati. *U.S.* W.

EUPATORIUM PURPUREUM. *U.S. Secondary.*

Gravel-root.

"Eupatorium purpureum. Radix. *The root.*" *U. S.*

Eupatorium. See EUPATORIUM PERFOLIATUM.

Eupatorium purpureum. Willd. *Sp. Plant.* iii. 1759. This species of Eupatorium is, like the preceding, a perennial herbaceous plant. Its stem is hollow, of a purple colour, five or six feet high, and furnished with ovate lanceolate, serrate, rugosely veined, slightly scabrous leaves, which are petiolate, and placed four or five together in the form of whorls. The flowers are purple, consisting of numerous florets contained in an eight-leaved calyx. It grows in swamps and other low grounds, from Canada to Virginia, and flowers in August and September. The root is the officinal portion.

This, according to Dr. Bigelow, has a bitter, aromatic, and astringent taste; and is said to operate as a diuretic. Its vulgar name of *gravel-root* indicates the popular estimation of its virtues. W.

EUPATORIUM TEUCRIFOLIUM. *U.S. Secondary.*

Wild Horehound.

"Eupatorium teucrifolium. Herba. *The Herb.*" *U.S.*

Eupatorium. See EUPATORIUM PERFOLIATUM.

Eupatorium teucrifolium. Willd. *Sp. Plant.* iii. 1753.—*E. pilosum.* Walt. *Flor. Car.* 199.—*E. verbenæfolium.* Mich. *Flor. Am.* ii. 98. The wild horehound is an indigenous perennial, with an herbaceous stem about two feet high, supporting sessile, distinct, ovate, acute, scabrous leaves, of which the lower are coarsely serrate at the base, the uppermost entire. The flowers are small, white, consisting of five florets within each calyx, and disposed in the form of a corymb. The plant grows in low wet places, from New England to Georgia, and is very abundant in the Southern States. It is in flower from August to November. The whole herb is employed.

In sensible properties it corresponds with the *E. perfoliatum,* though less bitter and disagreeable to the taste. It is said to be tonic, diaphoretic, diuretic, and aperient; and in the South is much employed as a domestic remedy in intermittents and other fevers, to which the country upon the seaboard is subject. Dr. Jones, formerly president of the Georgia Medical Society, was the first to make its properties known to the profession. It is usually administered infused in water. One quart of the infusion, containing the virtues of an ounce of the plant, may be given in divided doses during the day. W.

EUPHORBIA COROLLATA. *U.S. Secondary.*

Large Flowering Spurge.

"Euphorbia corollata. Radix. *The root.*" *U.S.*

Euphorbia. *Sex. Syst.* Dodecandria Trigynia. *Linn.;* Monœcia Monadelphia. *Michaux.*—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. *Involucrum* caliciform, eight to ten toothed, exterior alternate dentures glanduloid or petaloid. *Stamina* indefinite, twelve or more, rarely less; *filaments* articulated. *Receptacle* squamose. *Female flower* solitary stipitate, naked. *Capsule* three-grained. *Nuttall.*

In the flower of the Euphorbiæ, the stamina are arranged two or more together, in distinct parcels, which correspond in number with the inner segments of the calyx. These parcels were considered by Michaux as distinct male florets, while the central stipitate germ, with its three bifid styles, was considered as a distinct female floret, and the calyx took the name of an involucre. He accordingly placed the genus in the class and order *Monœcia Monadelphia*, and in this respect has been followed by most American botanists. The genus Euphorbia contains very numerous species, which have the common property of yielding a milky juice. They are herbaceous or shrubby, with or without leaves; and the leafless species, which are chiefly confined to the African deserts, have fleshy, naked, or spiny stems, resembling the genus Cactus. They nearly all afford products which act powerfully as emetics and cathartics, and in over-doses give rise to dangerous if not fatal prostration, with symptoms of inflamed gastro-intestinal mucous membrane. Their milky juice, which concretes on exposure to the air, usually possesses these properties in a high degree, and, in addition, that of powerfully irritating the skin when externally applied. Two species only are acknowledged in our national Pharmacopœia, the *E. corollata* and *E. Ipecacuanha*, which are both indigenous. The *E. hypericifolia*, which is also indigenous, has recently been very highly commended as a remedy in dysentery after due depletion, diarrhœa, menorrhagia, and leucorrhœa, by Dr. W. Zollickoffer of Baltimore. He infuses half an ounce of the dried leaves in a pint of boiling water, and gives half a fluidounce every hour in dysentery till the symptoms begin to yield, the same quantity after every evacuation in diarrhœa, and two fluidounces morning, noon, and night in menorrhagia and fluor albus. The herb, according to Dr. Zollickoffer, is at first sweetish, afterwards harsh and astringent to the taste, and from his experiments appears to contain tannin. Its effects upon the system are those of an astringent and feeble narcotic. It differs, therefore, considerably, both in sensible and medicinal properties, from most of the other species of Euphorbia. (*Am. Journ. of the Med. Sciences*, xi. 22.)

Euphorbia Corollata. Willd. *Sp. Plant.* ii. 916; Bigelow, *Am. Med. Bot.* iii. 119. The *blooming* or *large flowering spurge*, in common language frequently called *milk-weed*, is a tall erect plant, with a large, perennial, branching, yellowish root, which sends up several stems from two to five feet in height, round and generally simple. The leaves, which stand irregularly upon the stem, and without footstalks, are oblong, obovate, wedge-form or linear, flat or revolute at the margin, smooth in some plants, and hairy in others. The flowers are disposed upon a large terminal umbel, with a five-leaved involucrum, and five trifid and dichotomous rays, at each fork of which are two oblong bractes. The calyx is large, rotate, white, with five obtuse segments, closely resembling a corolla, from which the species has been named. At the base of these divisions are five interior smaller segments, which are described as nectaries by many systematic writers, while the larger are considered as belonging to a real corolla. The stamens are twelve, evolving gradually, with double anthers. Many flowers have only stamens. The pistil, when existing, is stipitate, nodding, rounded, with three bifid styles. The fruit is a smooth, three-celled, three-seeded capsule.

The plant grows in various parts of the United States, from Canada to Florida, and abounds in Maryland and Virginia. It prefers a dry, barren, and sandy soil, seldom growing in woods or on the borders of streams. Its flowers appear in July and August. The root is the only part used.

This, when full grown, is sometimes an inch in thickness, and two feet in length. It is without unpleasant taste, producing only a sense of heat a short time after it has been taken. The medical virtues are said to reside in the cortical portion, which is thick, and constitutes two-thirds of the whole root. They are taken up by water and alcohol, and remain in the extract formed by the evaporation of the decoction or tincture.

Medical Properties and Uses. In a full dose, the root of the *E. corollata* operates actively and with sufficient certainty as an emetic, producing ordinarily several discharges from the stomach, and not unfrequently acting with considerable energy upon the bowels. In quantities insufficient to vomit, it excites nausea, almost always followed by brisk purging. In still smaller doses it is diaphoretic and expectorant. It cannot, however, like ipecacuanha, be given largely in cases of insensibility of stomach, without endangering hypercatharsis with inflammation of the mucous coat of the stomach and bowels. It is in fact greatly inferior to this emetic in mildness, while it is no less inferior to the tartarized antimony in certainty. It is objectionable as a purge, in consequence of the nausea which it occasions, when given in cathartic doses. Dr. Zollickoffer of Baltimore was the first to introduce it to the particular notice of the medical profession. It is little prescribed, and seldom kept in the shops. The dose of the dried root as an emetic is from ten to twenty grains, as a cathartic from three to ten grains. The recent root, bruised and applied to the skin, produces vesication. W.

* * *

EUPHORBIA IPECACUANHA. *U.S. Secondary.*

Ipecacuanha Spurge.

"Euphorbia ipecacuanha. Radix. *The root.*" *U. S.*

Euphorbia. See EUPHORBIA COROLLATA.

Euphorbia Ipecacuanha. Willd. *Sp. Plant.* ii. 900; Barton, *Med. Bot.* i. 211; Bigelow, *Am. Med. Bot.* iii. 108. The *ipecacuanha spurge*, or, as it is sometimes called, *American ipecacuanha*, is a singular plant, varying so much in the shape and colour of its leaves, and in its whole aspect, that mere individual peculiarities might without care be attributed to a real specific difference. The root is perennial, of a yellowish colour, irregular, and very large, penetrating sometimes to the depth of six or seven feet in the sand, and in its thickest part measuring, when full grown, from three quarters of an inch to one inch and a half in diameter. The stems are numerous, herbaceous, erect or procumbent, smooth, dichotomous, jointed at the forks, white under the ground, red, pale-green, or yellow above, sometimes almost buried in the sand, usually forming thick low bunches upon its surface. The leaves are opposite, sessile, entire, smooth, generally oval, but sometimes round, obovate, or even lanceolate, or linear. They are small early in the spring, and increase in size with the age of the plant. Their colour varies from green to crimson. The flowers are solitary, and stand on long axillary peduncles. The calyx is spreading, with five exterior obtuse segments, and the same number of inner, smaller segments or nectaries. The fertile flowers have a roundish, drooping, pedicelled germ, crowned with six revolute stigmas. The capsule is three-celled, and contains three seeds.

The *E. Ipecacuanha* is indigenous, growing in pine barrens and other sandy places in the Middle and Southern States, especially along the seaboard, and abundant in New Jersey on the bank of the Delaware. It blooms from May to August. The root, which is the officinal portion, is, according to Dr. Barton, equally efficacious at whatever period collected.

The dried root is light and brittle, of a grayish colour externally, white within, inodorous, and of a sweetish not unpleasant taste. Its active principle has not been isolated. Dr. Bigelow inferred from his experiments, that it contained caoutchouc, resin, gum, and probably starch.

Medical Properties and Uses. It is an energetic, tolerably certain emetic, rather milder than the *E. corollata*, but, like that, disposed to act upon the bowels, and liable, if given in overdoses, to produce excessive nausea and vomiting, general prostration, and alarming hypercatharsis. It is therefore wholly unfit to supersede ipecacuanha. In small doses it is diaphoretic. The specific name of the plant indicates that the emetic property of the root has been long known. The late professor Barton alludes to it in his Collections; but it did not come into general notice till after the publication of Dr. W. P. C. Barton's Medical Botany. The dose of the powdered root is from ten to fifteen grains. W.

EUPHORBIÆ GUMMI-RESINA. *Lond.*

Euphorbium.

"Euphorbia officinarum. *Gummi-resina.*" *Lond.*

Off. Syn. EUPHORBIA CANARIENSIS. Gummi-resina. *Dub.*

Euphorbe, *Fr.;* Euphorbium, *Germ.;* Euforbio, *Ital., Span.*

Euphorbia. See EUPHORBIA COROLLATA.

Euphorbium is obtained from several species of Euphorbia, most abundantly from the *E. officinarum*, which grows in the North of Africa and at the Cape of Good Hope, the *E. Canariensis*, a native of the Canary Islands and Western Africa, and the *E. antiquorum*, inhabiting Egypt, Arabia, and the East Indies, and supposed to be the plant from which the ancients derived this resinous product. These species of Euphorbia bear a considerable resemblance in their general form to the *Cactus*, having leafless, jointed, angular stems, divided into branches of a similar structure, and furnished with double prickles at the angles. When wounded, they give out an acrid milky juice, which concretes upon the surface of the plant, and being removed, constitutes the euphorbium of commerce.

This occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical holes, produced by the prickles of the plant, around which the juice has concreted, and which sometimes remain in the holes. The masses are occasionally large and mixed with impurities. The surface is dull and smooth, bearing some resemblance to that of tragacanth; the consistence somewhat friable; the colour light yellowish or reddish; the odour scarcely perceptible; the taste at first slight, but afterwards excessively acrid and burning. The colour of the powder is yellowish. The sp. gr. of euphorbium is 1.124. Triturated with water it renders the liquid milky, and is partially dissolved. Alcohol dissolves a larger portion, forming a yellowish tincture, which becomes milky on the addition of water. Its constituents, according to Pelletier, are resin, wax, malate of lime, malate of potassa, lignin, bassorin, volatile oil, and water. Brandes found caoutchouc. Euphorbium contains no gum, and is therefore incorrectly called a gum-resin. The proportions of the ingredients are variously stated by different chemists, and probably vary in different specimens. The most abundant is resin, and the remainder consists chiefly of wax and malate of lime. The resin is excessively acrid, is soluble in alcohol, and when exposed to heat, melts, inflames, and burns with a brilliant flame, diffusing an agreeable odour. It is upon this principle that the acrimony of euphorbium chiefly depends.

Medical Properties and Uses. Euphorbium taken internally is emetic and cathartic, often acting with great violence, and in large doses producing severe gastric pain, excessive heat in the throat, and symptoms of great prostration. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended with incessant sneezing, and sometimes bloody discharges. They who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Largely diluted with wheat flour or starch, it may be used as an errhine in amaurosis, deafness, and other obstinate affections of the head. Externally applied, it inflames the skin, often producing vesication; and on the continent of Europe is sometimes used as an ingredient of epispastic preparations. It is employed in veterinary practice, with a view to its vesicating power. As an article of the materia medica, however, it may well be dispensed with, and it has been very properly omitted in the Pharmacopœia of the United States. W.

◆

EXTRACTUM GLYCYRRHIZÆ. *U.S.*

Liquorice.

"Glycyrrhiza glabra. Radicis extractum. *Extract of the root.*" *U.S.*

Off. Syn. EXTRACTUM GLYCYRRHIZÆ, *Lond.*, *Dub.*; EXTRACTUM GLYCYRRHIZÆ GLABRÆ, *Ed.*

Extrait de reglisse, *Fr.*; Süssholzsaft, *Germ.*; Sugo di liquirizia, *Ital.*; Regaliza en bollos, *Span.*

For an account of the *Glycyrrhiza glabra*, see article GLYCYRRHIZA.

The London and Dublin Colleges give directions for the preparation of this extract; but as it is never prepared in this country, it very properly occupies, in the United States Pharmacopœia, a place in the catalogue of the Materia Medica.

Liquorice is an article of export from the North of Spain, particularly

Catalonia, where it is obtained in the following manner. The roots of the *G. glabra* having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water till the liquid is saturated. The decoction is then allowed to rest, and after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract thus prepared is formed into rolls from five to six inches long, by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

Much liquorice is also prepared in Calabria, according to M. Fée, from the *G. echinata* which abounds in that country. The process is essentially the same with that just described, but conducted with greater care; and the Italian liquorice is purer and more valuable than the Spanish. We have been informed that most of the extract brought to this country comes from the ports of Leghorn and Messina.

Crude liquorice is in cylindrical rolls, somewhat flattened and covered with bay leaves. When good, it is very black, dry, brittle, breaking with a shining fracture, of a very sweet, peculiar, slightly acrid or bitterish taste, and almost entirely soluble in water. It is frequently, however, very impure, either from adulteration or improper preparation. Starch, sand, the juice of prunes, &c., are sometimes added; and carbonaceous matter, and even particles of copper are found in it, the latter arising from the boilers in which the decoction is evaporated. Four pounds of the extract have yielded two drachms and a half of metallic copper. (*Fée.*) It is rarely quite soluble in water. Neumann obtained 460 parts of watery extract from 480 of Spanish liquorice. A bitter and empyreumatic taste are signs of inferior quality. Before being used internally it generally requires to be purified.

The refined liquorice kept in the shops in small cylindrical pieces not thicker than a pipe stem, is prepared by dissolving the impure extract in water without boiling, straining the solution, and evaporating. The object of this process is to separate not only the insoluble impurities, but also the acrid oily substance, which is extracted by long boiling from the liquorice root, and is necessarily mixed with the unrefined extract. It is customary to add during the process a portion of sugar, and sometimes perhaps mucilage or glue; and flour or starch is a frequent adulteration. Excellent liquorice is prepared in some parts of England from the root cultivated in that country. The Pontefract cakes are small lozenges of liquorice of a very superior quality, made in the vicinity of Pomfret.

Medical Properties and Uses. Liquorice is a useful demulcent, much employed as an addition to cough mixtures, and frequently added to infusions or decoctions, in order to cover the taste or obtund the acrimony of the principal medicine. A piece of it held in the mouth and allowed slowly to dissolve, is often found to allay cough by sheathing the irritated membrane of the fauces. It is used in pharmacy to impart consistence to pills and troches, and to modify the taste of other medicines.

FERRUM.

Iron.

Fer, *Fr.;* Eisen, *Germ.;* Ferro, *Ital.;* Hierro, *Span.*

Iron is the most abundant and useful of the metals, and so interwoven with the wants of mankind, that the extent of its consumption by a nation may be taken as an index of its progress in civilization. It is universally diffused throughout nature, not only in the mineral kingdom, but also in vegetables and animals. There are very few minerals in which traces of it may not be found, and it is an essential constituent in many parts of animals, but particularly in the blood. It is one of the few metals which are devoid of deleterious action on the animal economy.

Iron occurs, 1. native; 2. sulphuretted, forming magnetic and cubic pyrites; 3. oxidized, embracing the magnetic, specular, red, brown, and argillaceous oxides of iron; 4. in saline combination, forming the carbonate, sulphate, phosphate, arseniate, and chromate of iron. Those minerals of iron which admit of being worked to advantage, are called iron ores. These include the different native oxides, and the carbonate (sparry iron). The best iron is obtained from those varieties of native oxide, usually called magnetic iron ore and specular iron ore. These occur very abundantly in Sweden, and furnish the superior iron of that country. As a general rule, those ores yield the best iron which occur in primitive formations.

Extraction. The mode of extracting iron from its ores varies somewhat with the nature of the ore; but the general principles of the operation are the same for all. The ore, previously roasted and coarsely pulverized, is exposed to the action of a strong heat in contact with carbonaceous matter, such as charcoal or coke, and in connexion with some flux, capable of fusing with the impurities of the ore. The flux varies with the nature of the ore, and is generally either lime or clay; lime being employed when the ore is argillaceous, clay when it is calcareous. The flux, whatever it may be, enters into fusion with the impurities, and forms what is called the slag; while the carbonaceous matter, acting on the oxide of iron, reduces it to the metallic state. The reduced metal, from its density, occupies the lower part of the furnace, and is protected from the action of the air by the melted slag which floats on its surface. When the reduction is completed, the slag is allowed to run out of a hole in the side of the furnace, and the melted metal, by an aperture at its bottom, the latter being received into oblong triangular moulds, where it solidifies in masses, known in commerce by the name of pig or cast iron. In this state the metal is brittle and far from being pure, as it is contaminated with a portion of charcoal, unreduced ore, and earthy impurities. It is purified, and thus brought to the state of malleable iron, by being fused by a strong heat, and subjected to the action of a current of air on its surface. By these means the undecomposed ore is reduced, the earthy impurities are made to rise to the surface as a slag, and the carbon is burnt out. As the metal approaches to purity, it becomes less and less fusible, and at last consolidates, though the temperature of the furnace continues the same. The metal is then taken out, and by means of ponderous hammers, or rollers, its particles are beaten or pressed together so as to form one tenacious mass. It is finally drawn out into bars of a convenient size, when it constitutes the malleable iron of commerce.

Iron mines occur in most countries, but more particularly in northern ones. In Spain the principal mines furnish sparry iron, and the red and brown oxides. The chief iron ores of France are the sparry iron, and the specular, brown, and argillaceous oxides, and of Germany, the sparry iron and brown oxide. The island of Elba is celebrated for its rich and abundant specular oxide. The ores which furnish the celebrated Swedish iron have already been indicated.

In the United States iron is abundant. The principal ores which are worked are the magnetic, brown, and argillaceous oxides. They occur in the greatest abundance in the states of New Hampshire, Massachusetts, Rhode-Island, Connecticut, New York, New Jersey, and Pennsylvania. The ores of the three last mentioned states rival the best Swedish in quality. In 1822, Cleaveland estimated the annual product of our iron mines at about 30,000 tons of bar iron, and 60,000 of cast iron.

Properties. Iron is a hard, malleable, very ductile and tenacious metal, of a grayish-white colour and fibrous texture, and having a slight styptic taste, and a sensible odour when rubbed. Its sp. gr. is about 7.7, and its fusing point very high. It possesses the magnetic and welding properties. It is combustible, and when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen gas. At a red heat, its surface is converted into black oxide, and by the combined agency of air and moisture at common temperatures, it becomes covered with a reddish matter, called *rust*, which consists of the hydrated peroxide. It combines with all the nonmetallic bodies, except hydrogen and nitrogen, and with most of the metals; its equivalent number being 28. It forms two regular oxides, a protoxide and peroxide; and these by combining together produce a third, of a black colour, formerly erroneously considered to be the protoxide. This last is called in the peculiar nomenclature of Berzelius, the *ferroso-ferric oxide;* but it is, perhaps, more convenient to designate it as the *black oxide.* The protoxide of iron is of a dark blue colour, attracted by the magnet, and spontaneously combustible in the air, being converted into peroxide. It is the base of green vitriol, and of the green salts of iron generally. It is very prone to absorb oxygen, and hence the salts which contain it are soon partially converted, when in solution, into persalts. It consists of one equivalent of iron 28, and one equiv. of oxygen 8 = 36. The peroxide is readily obtained pure by dissolving iron in nitro-muriatic acid, adding ammonia, and igniting the precipitate obtained. It is of a red colour, not attracted by the magnet, and forms salts, which for the most part have a reddish colour. It is composed of two equiv. of iron 56, and three of oxygen 24 = 80. It is, therefore, strictly speaking, a *sesquioxide.* The black oxide exists in the native magnetic oxide, and in certain ferruginous salts after they have absorbed a certain definite proportion of oxygen. It consists of one equiv. of protoxide 36, and one of peroxide 80 = 116. Iron, combined with minute portions of carbon, and perhaps of the radicals of silica and alumina, forms *steel*, a modification of iron formerly used in medicine, but now very properly laid aside. It also unites, when oxidized, with various acids, giving rise to an important class of salts, several of which, as the muriate, carbonate, sulphate, phosphate, ferrocyanate, tartrate, and acetate, are used in medicine.

Iron is readily detected, even in minute quantities, by bringing it to the state of peroxide in solution, and testing it with ferrocyanate of potassa, or tincture of galls, the former of which will strike a deep blue, the latter a black colour. The object of bringing it to the state of peroxide is readily effected by boiling the solution containing it with a little nitric acid.

Medical Properties. The preparations of iron are powerfully tonic, raising the pulse, promoting the secretions, and increasing the colouring matter of the blood. They are useful in diseases characterized by debility and relaxation of fibre, and a languid circulation, more especially when the consequence of inordinate discharges. The diseases in which they are most usually employed are chlorosis, hysteria, fluor albus, gleet, scrofula, rickets, chorea, and all passive hemorrhages. Chalybeates are also proper in palsy after the inflammatory excitement has subsided, in dyspepsia dependent upon deficient energy of the digestive functions, and in neuralgia. They are contra-indicated in all inflammatory diseases, producing, when injudiciously prescribed, heat, thirst, headach, difficulty of breathing, and other symptoms of an excited circulation. The medical effects of iron, as modified in its different combinations, will be noticed under the head of each preparation separately.

The following table embraces all the preparations of iron to be found in the United States and British Pharmacopœias, together with the synonymes.

Iron is officinal,—

FERRI FILUM. *U.S.*

Iron Wire.

FERRI RAMENTA. *U.S.*

Iron Filings.

Off. Syn. FERRUM. Ferri Ramenta et Fila, *Lond.;* FERRI FILA. FERRI LIMATURA, *Ed.;* FERRUM. Fila. Scobs, *Dub.*

Fil de fer, *Fr.;* Eisendraht, *Germ.;* Fil di ferro, *Ital.;* Hilo de hierro, *Span.*

Limailles de fer, *Fr.:* Eisenfeilicht, *Germ.;* Limatura di ferro, *Ital.;* Limadura de hierro. *Span.*

Iron, when employed in pharmaceutical operations, should be of the purest kind; and hence the different Pharmacopœias direct it, when wanted in small masses, to be in the form of iron wire, which is necessarily made from the softest and most malleable iron, and is readily cut into pieces of convenient size. The metal, however, for internal exhibition and for some preparations, requires to be finely subdivided, and hence it is officinal also in the form of filings.

Medical Properties of Iron Filings. Iron, in its uncombined state, has no action on the animal economy; and hence iron filings would prove inert, were it not that they met with acid in the stomach, or some other agent, whereby they become oxidized. That this change really takes place, is proved by the black stools to which they invariably give rise. During the solution of iron in the stomach, the oxygen furnished to the metal is derived from water, the hydrogen of which by being disengaged gives rise to unpleasant eructations. Iron filings are generally obtained from the workshops of the blacksmith; and as furnished from this source are generally very impure, and require, before exhibition, to undergo purification, for which a process is directed by the Edinburgh College. (See *Limatura Ferri Purificata.*) The other Pharmacopœias have no purified filings, and this is an omission of some importance; as the common filings are evidently too impure for internal use. The dose is from five to twenty grains, given in molasses, or made up into an electuary with honey, or into pills with some bitter extract. Upon the whole, there is reason to believe that no medical effects can be expected from iron exhibited in the metallic state, which cannot be as well obtained, and with less inconvenience to the patient, from its different combinations.

FERRUM. Oxydi Squamæ. *Dub.*

Scales of the Oxide of Iron.

Off. Syn. OXIDUM FERRI NIGRUM. *Ed.*

Batitures de fer, *Fr.;* Eisenschlag, *Germ.;* Scaglia di ferro, *Ital.;* Escamas de hierro, *Span.*

This form of oxidized iron is obtained when iron is heated to redness and subjected to the blows of a hammer on an anvil. The heat causes the iron to be covered with a thin crust of oxide, which is detached in scales during the hammering. These are formed abundantly in the operations of the blacksmith, and collect around the anvil.

Scales of iron consist of small, black, brittle masses, attracted by the magnet, and without taste or smell. When reduced to powder, they have a dull grayish-white colour. Their precise composition is not well settled; but it is certain that they do not consist of the regular *black oxide.* (See *Ferrum.*) The results of Mosander seem to show that they consist of two distinct layers; the inner, of uniform composition, consisting of six equiv. of protoxide to one of peroxide; and the outer, of a variable mixture of the two oxides, the peroxide predominating on the surface, and diminishing gradually inwards.

Medical Properties. These scales have the general medical properties of the ferruginous preparations, but are not fit for medicinal use until they have undergone preparation. The Dublin and Edinburgh Colleges give formulæ for this purpose, and designate the prepared substance by a distinct name. (See *Ferri Oxydum Nigrum,* Dub.) This is the only officinal preparation of the scales. B.

◆

FERRI FERROCYANAS. *U.S.*

Ferrocyanate of Iron.

Off. Syn. FERRI CYANURETUM. *Dub.*

Prussiate of iron, Cyanuret of iron, Prussian blue; Hydro-ferro-cyanate de peroxide de fer, Bleu de Prusse, *Fr.;* Berlinerblau, Pariserblau, *Germ.;* Azzuro di Berlino, *Ital.;* Azul de Prussia, *Span.*

Prussian blue was included in the materia medica list of the first United States Pharmacopœia, published in 1820, on account of its being connected indirectly with the preparation of hydrocyanic acid, and has been very properly retained in the revised edition of 1830. It was made officinal by the Dublin College, in their revised Pharmacopœia of 1826, for the same reason that induced its original insertion into our Pharmacopœia. The London and Edinburgh Colleges have not as yet adopted this substance, nor, indeed, any of the prussic compounds.

Prussian blue was discovered by accident in 1710, by a preparer of colours at Berlin, named Diesbach. Being desirous of precipitating a lake from a mixed solution of cochineal, alum, and sulphate of iron, by means of carbonate of potassa, he performed the experiment with an alkali which had been employed in connexion with animal matters, and unexpectedly obtained a blue precipitate. Following up the experiment, he was enabled to determine the precise ingredients necessary for its formation, and thus laid the foundation of the manufacture of this beautiful pigment, which came to be called, from the country of its discovery, Prussian blue. The mode of preparing it was kept secret until 1724, when Woodward published the process in the Philosophical Transactions of London. Since that time it has been extensively manufactured on a large scale for the purposes of the arts.

Preparation. On a small scale, Prussian blue may be obtained perfectly pure, by double decomposition between ferrocyanate of potassa, and an acid solution of persulphate or permuriate of iron. In the arts the process is as follows. A mixture made of equal parts of carbonate of potassa (pearlash of commerce), and animal matter, such as dried blood, hair, the shavings of horn, &c., is calcined at a red heat in an iron vessel, until it becomes pasty. The mass, when cold, is thrown by portions at a time into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter; and the clear solution obtained is precipitated by a mixed solution of two parts of alum and one of the sulphate of the protoxide of iron. An effervescence occurs, due principally to carbonic acid; and a very abundant precipitate takes place, of a blackish-brown colour. This precipitate is washed by decantation, by means of a large quantity of water, which is renewed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes, successively, greenish-brown, blueish-brown, and finally deep blue. When of the latter colour, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses, dried, and thrown into commerce.

Properties. Prussian blue is an insipid, inodorous substance, generally in the form of oblong rectangular cakes, of a rich deep blue colour. It is heavier than water, and its fracture has an appearance resembling bronze, which is distinguished from the similar appearance of indigo by its being removed when rubbed with the nail, whereas in indigo, it is increased by friction. It is completely insoluble in water or alcohol, as also in the mineral acids, except the sulphuric. In this acid in a concentrated state it dissolves, forming a white compound, from which the Prussian blue is precipitated unchanged by water. Nitric acid decomposes it, and strong muriatic acid takes up a part of the iron, and gives rise to the formation of ferrocyanic acid. Boiled with peroxide of mercury it generates bicyanuret of mercury. (See *Hydrargyri Cyanuretum.*) Exposed to destructive distillation, it furnishes at first a little water and hydrocyanate of ammonia, and afterwards carbonate of ammonia; and there remains in the retort a black carbonaceous residue of tritocarburet of iron.

Composition. Prussian blue, when pure, is, according to Berzelius, a double cyanuret, consisting of three eq. of the protocyanuret of iron, united with two eq. of the sesquicyanuret of the same metal. Its entire composition is represented by nine eq. of cyanogen, combined with seven eq. of iron. The theory of its formation is complicated. By the calcination of the animal matters with pearlash, cyanuret of potassium is formed. This, by double decomposition with the protoxide of iron of the sulphate of iron, gives rise to the protocyanuret of iron, and potassa, the latter of which unites with the sulphuric acid, so as to form sulphate of potassa. Six eq. of protocyanuret of iron, thus formed, are acted on by the oxygen of the air, with the effect of detaching two eq. of iron, which by uniting with three eq. of oxygen, become peroxide of iron. The six eq. of protocyanuret, by undergoing this change, are converted into a compound of six eq. of cyanogen and four eq. of iron, corresponding with two eq. of the sesquicyanuret of iron. The two eq. of sesquicyanuret, thus generated, combine with three eq. of protocyanuret of iron, to form the pure Prussian blue. The sulphate of potassa formed is washed away; but the peroxide of iron remains in the Prussian blue of commerce as an impurity. Another impurity in the commercial pigment is alumina, which is precipitated from the alum, employed conjointly with the protosulphate of iron as a precipitant. This earth serves to give the pigment a body, which renders it useful in the arts. For an account of the properties and composition of *cyanogen*, see *Acidum Hydrocyanicum. U. S.*

Medical Properties, &c. Prussian blue is supposed to act as a tonic, febrifuge, and alterative. Dr. Zollickoffer of Maryland has recommended it as a remedy in intermittent and remittent fevers, and deems it to be particularly adapted to such cases occurring in children, on account of the smallness of the dose and its want of taste. He considers it more certain, prompt, and efficacious than the bark; while it has the advantage of being admissible in the state of pyrexia, and of not disagreeing with the most irritable stomach.* It has also been used by Dr. Kirchoff of Ghent in epilepsy with good success. Dr. Bridges of Philadelphia exhibited it in a case of severe and protracted neuralgia of the face, with very considerable relief, after all the more usual remedies in this complaint had been tried with little or no benefit. In the course of two days, the violence of the disease was subdued, and in a short period afterwards a greater freedom from pain was occasioned than had been experienced for many years. The medicine, in this case, produced no perceptible effect, besides relieving the disease, except that of a very mild tonic.

The dose of Prussian blue for an adult is about five grains, repeated three times a day, and gradually increased according to its effects. It must be here recollected, however, that we allude to the commercial substance, which contains a considerable quantity of alumina and peroxide of iron, and not to the chemically pure cyanuret, of which the dose is necessarily smaller. It is sometimes employed as an application to ill-conditioned ulcers, in the proportion of a drachm to an ounce of some simple ointment. Its only pharmaceutical use is to form bicyanuret of mercury, as a preliminary step to the preparation of hydrocyanic acid.

* See "A Treatise on the Use of Prussian Blue in Intermitting and Remitting Fevers, by William Zollickoffer, M. D." Frederick, Maryland, 1822.

Ficus Carica. Willd. *Sp. Plant.* iv. 1131; Woodv. *Med. Bot.* p. 714. t. 244. The fig-tree, though usually not more than twelve feet in height, sometimes rises in warm climates to twenty-five or even thirty feet. Its trunk, which seldom exceeds seven inches in diameter, is divided into numerous spreading branches, covered with a brown or ash-coloured bark. Its large, palmate leaves, usually divided into five obtuse lobes, are deep green and shining upon their upper surface, pale green and downy beneath, and stand alternately on strong round footstalks. The flowers are situated within a common receptacle, placed solitarily upon a short peduncle in the axils of the upper leaves. This receptacle, the walls of which become thick and fleshy, constitutes what is commonly called the fruit; though this term is, strictly speaking, applicable to the small seeds found in great numbers on the internal surface of the receptacle, to which they are attached by fleshy pedicels. Cultivation has produced in the fig, as in the apple and peach, an almost infinite diversity in shape, size, colour, and taste. It is usually, however, turbinate or top-shaped, umbilicate at the large extremity, of the size of a small pear, of a whitish, yellowish, or reddish colour, and of a mild, mucilaginous, saccharine flavour.

The fig-tree is supposed to have come originally from the Levant. It was introduced at a very early period into various parts of the South of Europe, and is now very common throughout the whole basin of the Mediterranean, particularly in Italy and France. To hasten the maturation of the fruit, it is customary to puncture it with a sharp pointed instrument covered with olive oil. The ancient process of *caprification* is still practised in the Levant. It consists in attaching branches of the wild fig-tree to the cultivated plant. The fruit of the former contains great numbers of the eggs of an insect of the genus Cynips, the larvæ of which, as soon as they are hatched, spread themselves over the cultivated fruit, and by conveying the pollen of the male organs over which they pass to the female florets, hasten the impregnation of the latter, and cause the fig to come quickly to perfection, which might otherwise ripen very slowly, or wither and drop off before maturity. Some authors attribute the effect to the piercing of the fruit by the young insects.

The figs, when perfectly ripe, are dried by the heat of the sun or in ovens. Those brought to the United States come chiefly from Smyrna, packed in drums or boxes. They are more or less compressed, and are usually covered in cold weather with a whitish saccharine efflorescence, which melts in the middle of summer and renders them moist. The best are yellowish or brownish, somewhat translucent when held to the light, and filled with a sweet viscid pulp, in which are lodged numerous small yellow seeds. They are much more saccharine than the fresh fruit. Their chief constituents are mucilage and sugar.

Medical Properties and Uses. Figs are nutritious, laxative, and demulcent. In the fresh state, they are considered in the countries where they grow a wholesome and agreeable aliment. As we obtain them, they are apt when eaten freely, to produce flatulence, pain in the bowels, and diarrhœa. Their chief medical use is as a laxative article of diet in cases of constipation. They occasionally enter into demulcent decoctions; and when roasted or boiled, and split open, may be applied as a suppurative cataplasm to parts upon which an ordinary poultice cannot be conveniently retained.

Gen. Ch. Fructification in roundish points, scattered, not marginal. *Involucre* umbilicated, open almost on every side. *Smith.*

Aspidium Filix Mas. Willd. *Sp. Plant.* v. 259; Smith, *Flor. Britan.*—*Polypodium Filix Mas.* Linn.; Woodv. *Med. Bot.* p. 795. t. 267. The male fern has a perennial, horizontal root, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe or footstalk, and midrib, are thickly beset with brown, tough, transparent scales; the frond itself is oval lanceolate, acute, pinnate, and of a bright green colour. The pinnæ or leaflets are remote below, approach more nearly as they ascend, and run together at the summit of the leaf. They are deeply divided into lobes, which are of an oval shape, crenate at the edges, and gradually diminish from the base of the pinna to the apex. The fructification is in small dots on the back of each lobe, placed in two rows near the base, and distant from the edges.

The male fern is indigenous, growing in shady pine forests from New Jersey to Virginia. (*Pursh.*) It is a native also of Europe, Asia, and the North of Africa. In the American plant, the leaflets are said by Pursh to be more obtuse, and oftener doubly serrated than in the European.

The proper period for collecting the root is during the summer, when, according to M. Peschier of Geneva, it abounds more in the active principle than at any other season. The same gentleman informs us that it deteriorates rapidly when kept, and in about two years becomes entirely inert. The roots of other species of fern are frequently substituted for the officinal; and in the dried state it is difficult to distinguish them.

Properties, &c. As taken from the ground, the root consists of a long cylindrical caudex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes, which are an inch or two in length, from two to four lines thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the root with thin silky scales, of a light brown colour. From between these remains of the footstalks emerge numerous small radical fibres. The whole root thus constituted, presents a somewhat flexible, cylindrical mass, one or two inches thick, and a foot or more in length. In this form, however, it is not usually found in our shops. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leaf stalks before described, with a small portion of the substance of the root attached to their base, where they are surrounded by the silky scales. These fragments ordinarily present the appearance of having been long kept, and are probably, as a general rule, much deteriorated by time. The male fern root is brought to us from Europe, but might perhaps be more advantageously collected in this country. The following observations are made by Geiger in relation to its collection and preservation. The inner parts of the fresh root and of the portions of stalk attached to it, are fleshy and of a light yellowish-green colour. In collecting them, all the black discoloured portions should be cut away, the fibres and scales separated, and only the sound green parts preserved. These should be immediately but carefully dried, and then reduced to powder; and the powder should be kept in small well stopped glass bottles. The powder thus prepared has a pale yellowish colour with a greenish tinge.

Dried fern root is externally of a brown colour, internally yellowish-white or reddish, with a peculiar but feeble odour, which is most obvious in the powder and decoction, and a sweetish, bitter, astringent, nauseous taste. From the analysis of M. Morin, an apothecary of Rouen, it appears to contain a volatile oil, a fixed oil, gallic and acetic acids, uncrystallizable sugar, tannin, starch, a gelatinous matter insoluble in water and alcohol, lignin, and various earthy and saline substances. M. Peschier found its active principle soluble in ether. According to this chemist, its constituents are adipocire, an aromatic volatile oil, an aromatic and virose fixed oil, a brown resin, a green colouring principle, a reddish-brown colouring principle, extractive, acetic acid, and muriate of potassa. Ether extracts the adipocire along with the active ingredient, but deposites the former on standing.

In powdering the root the internal parenchymatous portion only should be preserved.

Medical Properties and Uses. Male fern is slightly tonic and astringent; but produces, when taken internally, no very obvious effects upon the system. It was used by the ancients as a vermifuge; and is mentioned in the works of Dioscorides, Theophrastus, Galen, and Pliny. Its anthelmintic powers were also noticed by some of the earlier modern writers, among whom was Hoffmann. But it does not appear to have been generally known to the profession, till attention was attracted to it, about the year 1775, by the publication of the mode of treating tænia employed by Madame Nouffer. This lady, who was the widow of a surgeon in Switzerland, had acquired great celebrity in the cure of tape-worm by a secret remedy. Her success was such as to attract the attention of the medical profession at Paris; and some of the most eminent physicians of that city, who were deputed to examine into the subject, having reported favourably of the remedy, the secret was purchased by the king of France, and published by his order. The outlines of her plan were to give a dose of the powdered root of the male fern, and two hours afterwards a powerful cathartic, to be followed, if it should not operate in due time, by some purging salt; and this process was to be repeated with proper intervals, till the worm should be evacuated. A German physician by the name of Herrenschwand, had used the male fern in a manner somewhat similar before Madame Nouffer's secret was known. The remedy became very popular for a time, and was found successful in numerous instances; but the profession has now generally settled down in the opinion that the good which resulted was owing more to the purgatives than to the fern. Instances, however, are recorded, in which cures were effected by the root without the use of cathartics; and amid the general scepticism on the subject, physicians are still found who warmly advocate the anthelmintic powers of the medicine. Dr. Peschier assures us that, in the course of nine months, one hundred and fifty tape-worms had been expelled by the ethereal extract of the male fern root. Dr. Ebers has found the same preparation completely successful in curing eight cases of tænia. (*Journ. de Chimie Médicale, Fev.* 1829.) He states that the medicine acts specifically against the worm, which it speedily destroys, and thus favours its expulsion from the body, without producing any severe or unpleasant symptoms. The testimony of Brera is also strongly in favour of the remedy, which he has found effectual even against the armed tænia. Perhaps the different results obtained by different practitioners may in part be ascribed to the variable strength and character of the root, dependent upon the season at which it was collected, and the length of time it has been kept.

The medicine may be given in powder, or, as recommended by Dr. Peschier, in ethereal extract. The dose of the powder is from one to three drachms, to be given in the form of electuary or emulsion, and repeated morning and evening for one or two days successively. The dose of the extract is from twelve to twenty-four grains. The decoction has also been employed in the proportion of an ounce of the root to a pint of water. It is customary to follow the medicine by some brisk cathartic, though Dr. Peschier does not consider this essential. Dr. Mayor of Geneva recommends very highly the oil of fern, in the dose of from thirty to fifty drops, one half to be taken at night, the other half in the morning, and followed at the interval of an hour, by an ounce and a half of castor oil. W.

FŒNICULUM. *U.S.*

Fennel Seed.

"Anethum fœniculum. Semina. *The seeds.*" *U. S.*

Off. Syn. FŒNICULI SEMINA. Anethum Fœniculum. Semina. *Lond.:* ANETHI FŒNICULI SEMINA. *Ed.;* FŒNICULUM. ANETHUM FŒNICULUM. Semina. *Dub.*

Fenouil, *Fr.;* Fenchel, *Germ.;* Finnocchio, *Ital.;* Hinojo, *Span.*

Anethum. See ANETHI SEMINA.

Anethum Fœniculum. Willd. *Sp. Plant.* i. 1469; Woodv. *Med. Bot.* p. 127. t. 49. Fennel has a perennial, tapering root, and an annual, erect, round, striated, smooth, green, and branching stem, which usually rises three or four feet in height. The leaves, which stand alternately at the joints of the stem, upon membranous striated sheathes, are many times pinnate, with long, linear, pointed, smooth, deep green, leaflets. The flowers are yellow, and form large, many-rayed umbels, destitute both of general and partial involucres. The corolla consists of five ovate, pointed leaflets, with their extremities turned inwards. The flower is succeeded by two ovate seeds.

There are several varieties of this plant; but the sweet fennel, derived originally from the South of Europe, and cultivated in our gardens, is the one which furnishes the seeds of the shops. The whole plant has an aromatic odour and taste, dependent on a volatile oil by which it is pervaded. The roots were formerly employed in medicine, but are greatly inferior in virtue to the seeds, which are now the only officinal portion. These are sometimes imported; but those produced in our own gardens are perhaps preferable on account of their greater freshness.

Fennel seeds are oblong oval, from one to three or four lines in length, flat on one side, convex on the other, not unfrequently connected by their flat surfaces, straight or slightly curved, of a grayish-green colour, with longitudinal yellowish ridges on the convex surface. Their odour is fragrant, their taste warm, sweet, and agreeably aromatic. The seeds of domestic growth are usually smaller and darker, but sweeter than the imported. They impart their virtues to hot water, but more abundantly to alcohol. Their essential oil may be separated by distillation with water. (See *Oleum Fœniculi.*) They contain also fixed oil. Neumann obtained 20 parts of the former, and 120 of the latter, from 960 parts of the seeds.

Medical Properties and Uses. Fennel-seed is among our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicines, particularly senna and rhubarb. It is recommended for these purposes by the absence of any very highly excitant property. The infusion, prepared by introducing two or three drachms of the seeds into a pint of boiling water, is the form usually preferred. The dose of the bruised or powdered seeds is from a scruple to half a drachm. In infantile cases, the infusion is frequently employed as an enema to produce the expulsion of flatus.

FRASERA. *U.S. Secondary.*

American Columbo.

"Frasera Walteri. Radix. *The root.*" *U. S.*

Frasera. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Gentianeæ.

Gen. Ch. *Calyx* deeply four-parted. *Corolla* four-parted, spreading; segments oval, with a bearded, orbicular gland in the middle of each. *Capsule* compressed, partly marginated, one-celled. *Seeds* few, imbricated, large, elliptical, with a membranaceous margin. *Nuttall.*

Frasera Walteri. Michaux, *Flor. Bor. Americ.* i. 96; *Med. Bot.* ii. 103. —*F. Carolinensis.* Walter. This is one of our most elegant indigenous plants, and the only one of its genus hitherto discovered. From the root, which is triennial, long, spindleshaped, horizontal, fleshy, and of a yellow colour, a strong, succulent, solid, smooth stem rises, from five to ten feet in height. The leaves are sessile, entire, glabrous, of a deep green colour, and disposed in whorls, which commence at the root, and ascend to the summit with successively diminishing intervals. The radical leaves, from five to twelve in number, are elliptical, obtuse, a foot or more in length by about four inches in breadth, and lie upon the ground in the form of a star. Those constituting the whorls upon the stem are successively smaller as they ascend—the lowest oblong lanceolate, the upper lanceolate and pointed. The flowers are numerous, large, of a yellowish-white colour, and disposed in a beautiful terminal pyramidal panicle, from one to five feet long, the branches of which spring from the axils of the upper leaves. The segments of the calyx are lanceolate, acute, and somewhat shorter than those of the corolla. The filaments are inserted into the base of the corolla between its segments, which they do not equal in length. The anthers are oblong and notched at the base. The germ is oblong ovate, compressed, and gradually tapers into the style, which terminates in a bifid stigma. The fruit is an oval, acuminate, compressed, two-valved, one-celled, yellow capsule, containing from eight to twelve flat, elliptical seeds.

The Frasera flourishes in the southern and western portions of the United States, and in many situations is very abundant, especially in Arkansas and Missouri. It prefers rich woodlands and moist meadows. The period of flowering is from May to July; but the stem and flowers are produced only in the third year, the radical leaves being the only part of the plant which previously appears above ground. From this manner of growth it is inferred, that the root should be collected in the autumn of the second or the spring of the third year. Before being dried, it should be cut into transverse slices.

As usually found in the market, frasera is in pieces irregularly circular, an eighth of an inch or more in thickness, about an inch in diameter, somewhat shrunk in the middle, consisting of a central medullary matter and an exterior cortical portion, of a yellowish colour on the cut surfaces, with a light reddish-brown epidermis. In appearance these pieces bear some resemblance to columbo, but may be easily distinguished by the greater uniformity of their internal structure, the absence of concentric and radiating lines, and their purer yellow colour without a greenish tinge. Their taste is bitter and sweetish. Water and diluted alcohol extract their virtues, and the tincture throws down a precipitate upon the addition of water, but is not disturbed by tincture of galls; thus affording additional means of distinguishing the root from columbo.

Medical Properties and Uses. Frasera is a mild tonic, calculated to meet the same indications with the other simple bitters. It has been thought to resemble columbo in medical properties as well as in appearance, and hence has received the popular name of *American columbo;* but experience has not confirmed the high estimate which was at one time formed of its virtues; and though occasionally employed in some parts of the country, it has failed to supplant the tonic of Mozambique. It may be given in powder or infusion. The dose of the former is from thirty grains to a drachm, that of an infusion, made in the proportion of an ounce of the bruised root to a pint of boiling water, is one or two fluidounces, to be repeated several times a day.

The fresh root is said to operate as an emetic and cathartic, and is sometimes given with a view to the latter effect. W.

◆

FUCUS. *Lond.*

Sea-wrack. Bladder-wrack.

"Fucus vesiculosus." *Lond.*

Off. Syn. FUCUS VESICULOSUS. Herba cum fructu. *Dub.*

Fucus. *Sex. Syst.* Cryptogamia Algæ.—*Nat. Ord.* Algæ.

Gen. Ch. Male. *Vesicles* smooth, hollow, with villose hairs within, interwoven. Female. *Vesicles* smooth, filled with jelly, sprinkled with immersed grains, prominent at the tip. *Seeds* solitary. *Thomson's Dispensatory.*

Fucus Vesiculosus. Turner's *Fuci.* ii. 44. This sea-weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet high, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green colour. Small spherical vesicles, filled with air, are immersed in the frond near the midrib. The fruit consists of roundish, compressed receptacles, at the ends of the branches, filled with a clear tasteless mucus. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coast of Scotland and of France, it is much used in the preparation of kelp. It is also employed as a manure, and is mixed with the fodder of cattle.

It has a peculiar odour, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are by no means satisfactory. It contains a large quantity of soda in saline combination, and iodine according to Gaultier de Claubry, in the state of hydriodate of potassa. These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels.

Medical Properties, &c. The charcoal of this plant has long had the reputation of a deobstruent, and been given in goitre and scrofulous swellings. Its virtues were formerly ascribed chiefly to the carbonate of soda, in which it abounds; but since the discovery of the medical properties of iodine, this has been considered as its most active ingredient. The mucus contained in the vesicles was applied externally, with advantage, by Dr. Russel, as a resolvent in scrofulous tumours.

Other species of Fucus are in all probability possessed of similar properties. Many of them contain a gelatinous matter, and a saccharine principle analogous to mannite; and some are used as aliment in times of scarcity by the wretched inhabitants of the coasts where they are collected. The *F. Helminthocorton* has some reputation in Europe as an anthelmintic. It is used in the form of decoction. W.

GALBANUM. *U.S.*

Galbanum.

"Bubon galbanum. Succus concretus. *The concrete juice.*" *U.S.*

Off. Syn. GALBANI GUMMI-RESINA. Bubon Galbanum. Gummi-resina. *Lond.;* BUBONIS GALBANI GUMMI-RESINA. *Ed.;* GALBANUM. BUBON GALBANUM. Gummi-resina. *Dub.*

Galbanum, *Fr.;* Mutterharz, *Germ.;* Galbano, *Ital., Span.*

GALBANUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Fruit* ovate, striated, villose. *Willd.*

Bubon Galbanum. Willd. *Sp. Plant.* i. 1439; Woodv. *Med. Bot.* p. 98. t. 40.—*Selinum Galbanum.* Sprengel. This species of Bubon is an undershrub, several feet in height, with a stem which is ligneous towards the base, but in the upper part, jointed, branching, leafy, and covered with a glaucous exudation. The lower leaves are nearly tripinnate, and stand upon footstalks which embrace the stem; the uppermost are almost simple, three-lobed, irregularly serrated, but entire near the base, thickish, and of a sea-green colour. The flowers are yellow and arranged in terminal umbels, of which the principal is plano-convex, and surmounts the main stem. The involucres and involucels are composed of numerous simple, narrow, lance-shaped leaflets. Each flower is followed by two brownish, oval, striated seeds with membranous borders. The plant grows on the eastern coast of Africa, from Nubia to the Cape of Good Hope, and is said also to be a native of Syria. It is at present, however, denied that this is the true galbanum plant, which is considered by Mr. Don as forming a new genus allied to Siler, and for which he proposes the name of *Galbanum officinale.* (*Trans. Lin. Soc.* xvi. 603.) Galbanum is obtained from it by making incisions into the stem, or cutting it off a short distance above the root. A cream-coloured juice exudes, which concretes upon exposure to the air. A small portion of juice also exudes spontaneously from the joints, and hardens in the shape of tears. The drug is brought from the Levant.

Properties. The form in which galbanum usually appears is that of masses, composed of whitish, reddish, or yellowish tears, irregularly agglutinated by a darker coloured substance, more or less translucent, and generally mixed with pieces of stalk, seeds, or other foreign matters. It is also found, though very rarely if at all in our markets, in the state of separate tears, of a yellowish-white colour, shining externally as if varnished, and of an oily aspect. Galbanum has in cool weather the consistence of firm wax; but softens in summer, and by the heat of the hand is rendered ductile and adhesive. At the temperature of boiling water it is sufficiently liquid to admit of being strained. A dark brown or blackish colour, a consistence always soft, the absence of whitish grains, and the intermixture of earthy impurities, are signs of inferiority.

The odour of galbanum is peculiar and disagreeable, but not alliaceous like that of sagapenum. Its taste is bitterish, warm, and acrid. Its specific gravity is 1.212. When triturated with water it forms an imperfect milky solution, which upon standing deposites the greater portion of what was taken up. Wine and vinegar act upon it in a similar manner. Alcohol dissolves a considerable proportion, forming a yellow tincture, which has the smell and taste of galbanum, and becomes milky by the addition of water, but affords no precipitate. In dilute alcohol it is wholly soluble, with the exception of impurities. One hundred parts of it yielded to M. Pelletier, 66.86 parts of resin, 19.28 of gum, 6.34 of volatile oil including the loss, 7.52 of wood and impurities, with traces of the supermalate of lime. It is, therefore, entitled to rank with the *gum-resins.* By distillation at the temperature of about 250° F., the essential oil is obtained of a fine indigo blue colour which it imparts to alcohol. Procured by distillation with water, it is colourless, and becomes yellowish by age. It is lighter than water.

Medical Properties and Uses. Galbanum is stimulant, expectorant, and antispasmodic; and may be considered as intermediate in power between ammoniac and assafetida. It is, however, much less employed than either of these gum-resins, and in the United States is seldom or never prescribed internally. The complaints to which it was formerly thought applicable, were chiefly chronic affections of the bronchial mucous membrane, amenorrhœa, and chronic rheumatism. It is occasionally applied externally in the shape of plaster to indolent swellings, with the view of promoting resolution or suppuration. Galbanum was known to the ancients. The dose is from ten to twenty grains, and may be given in pill, or triturated with gum Arabic, sugar, and water, so as to form an emulsion.

GALLA. *U.S.*

Galls.

"Quercus infectoria. Cyniphis nidus." *The nest of the Cynips quercûs folii." U.S.*

Off. Syn. GALLÆ. Cynips quercûs folii. Nidus. *Lond.;* GALLA. *Ex variis quercûs speciebus. Ed.;* GALLÆ. QUERCUS INFECTORIA. *Dub.*

Noix de galle, *Fr.;* Galläpfel, *Germ.;* Galla, *Ital.;* Agallas de Levante, *Span.*

Many vegetables, when pierced by certain insects, particularly those of the genus *Cynips,* are affected at the points of puncture with a morbid action, resulting in the production of excrescences, which, as they are derived from the proper juices of the plant, partake more or less of its predominant chemical character. Most species of oak are susceptible of this kind of action; and the resulting excrescences, having in a high degree the astringency of the plant on which they grow, have been employed for various practical purposes. They are known by the name of *galls*, a term which, as well as their employment in medicine, has been handed down to us from the ancients. The *Quercus infectoria*, *Q. Ægilops*, *Q. excelsa*, *Q. Ilex*, *Q. Cerris*, and *Q. Robur*, have all been particularized as occasionally affording this product; but it is now generally admitted, upon the authority of Olivier, that the officinal galls are derived chiefly, if not exclusively, from the *Q. infectoria*, and this is recognised as their source in the Pharmacopœias of the United States and of Dublin.

QUERCUS. See QUERCUS ALBA.

Q. infectoria. Willd. *Sp. Plant.* iv. 436; Olivier, *Voy, Or.* t. 14 *et* 15. The *dyers' oak* is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are obtusely toothed, smooth, of a bright green colour on both sides, and stand on short footstalks. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy, and scaly. This species of Quercus grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. Captain M. Kinneir found it also in Armenia and Kurdistan; General Hardwicke observed it growing in the neighbourhood of Adwanie; and it probably pervades the middle latitudes of Asia.

The gall originates from the puncture of the *Cynips quercûsfolii* of Linnæus, the *Dioplepsis gallæ tinctoriæ* of Geoffroy, a hymenopterous insect or fly, with a fawn-coloured body, dark antennæ, and upper part of its abdomen shining brown. The insect pierces the shoots of the young boughs, and deposites its egg in the wound. This irritates the vessels of the part, and a small tumour very speedily rises, which appears to be the result of a morbid secretion, and upon examination by the microscope exhibits no signs of proper vegetable fibre. The egg grows with the gall, and is soon converted into a larva, which feeds upon the vegetable matter by which it is surrounded, and thus forms a cavity in the centre of the tumour. The insect at length assumes the form of a fly, and escapes by eating its way out of the nut. The galls are in perfection when they have attained their full size, and before the egg has been hatched, or the fly has escaped. Collected at this period, they are called, from their dark colour, *blue*, or *green*, or *black galls*, and are most highly esteemed. Those which are gathered later, and which have been injured by the insect, are called *white galls*. They are usually larger, less heavy and compact, and of a lighter colour than the former; and are considered much inferior.

The galls collected in Syria and Asia Minor are brought to this country chiefly from the ports of Smyrna and Trieste. As they are produced abundantly in the vicinity of Aleppo, it has been customary to designate them by the name of that city; though the designation, however correct it may formerly have been, is now wholly inapplicable, as they are obtained from many other places; and the produce of different parts of Asiatic Turkey is not capable of being discriminated, at least in our markets. We have been informed, that, within a few years, great quantities of galls very closely resembling those from the Mediterranean have been brought to the United States from Calcutta. Whether they are the product of Hindostan, or taken thither from other countries, we are unable to decide with certainty. Ainslie is inclined to think that most of the galls found in the markets of India are imported from Persia by the Arab merchants. We are, nevertheless, informed that they are among the products of Moultan; and it is highly probable that they grow upon some of the other astringent vegetables, besides the oak, which flourish in Hindostan.

The galls of France and other southern countries of Europe have a smooth, shining, reddish surface, are little esteemed, and are seldom brought to the United States.

A species of nut was not many years since commonly sold in our markets, and is still found in some of the shops, under the name of *white galls*, to which, however, it bears not the slightest resemblance either in appearance or structure. It consists of an outer shell enclosing a hard kernel, is an inch or more in length, thick in the middle, somewhat pointed at both extremities, of a dull white or brownish colour, and is probably a species of *myrobalans*. To the taste it is powerfully astringent.

Properties. Galls are nearly round, from the size of a pea to that of a very large cherry, with a surface usually studded with small tuberosities, in the intervals of which it is smooth. The best are externally of a bluish or lead colour, internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the centre, indicating the presence of the undeveloped or decayed insect. Their powder has some shade of gray. Those of an inferior quality are of a lighter colour, sometimes reddish or nearly white, of a loose texture, with a large cavity in the centre, communicating externally by a small hole through which the fly has escaped. Galls are inodorous, and have a bitter very astringent taste. From 500 parts Sir H. Davy obtained 185 parts of matter soluble in water, of which, according to his analysis, 130 were tannin, 31 gallic acid with a little extractive, 12 mucilage and matter rendered insoluble by evaporation, and 12 saline matter and calcareous earth. Other chemists have found a larger proportion of tannin and gallic acid. Braconnot discovered the presence of a small quantity of another acid, to which he gave the name *ellagic*, derived from *galle*, the French name for galls, by reversing the order of the letters. According to M. Pelouse, however, neither gallic nor ellagic acid preexists in galls, being formed by the reaction of the atmospheric oxygen upon their tannin. (*Journ. de Pharm.* xx. 359.) Galls also yielded to Professor Branchi, by distillation with water, a concrete volatile oil. All their soluble matter is taken up by forty times their weight of boiling water, and the residue is tasteless: alcohol dissolves seven parts in ten, ether five parts. (*Thomson's Dispensatory.*) A saturated decoction of galls deposites upon cooling a copious pale yellow precipitate. The infusion or tincture affords precipitates with sulphuric and muriatic acids, lime-water, carbonate of ammonia, and carbonate of potassa; with solutions of acetate and sub-acetate of lead, the sulphates of copper and iron, the nitrates of silver and mercury, and tartrate of antimony and potassa; with the infusions of Peruvian bark, columbo, opium, and many other vegetables, especially those containing proximate alkaline principles, with most of which gallic acid or tannin forms insoluble compounds. The solution of gelatin also produces a precipitate. The infusion of galls reddens litmus paper, is rendered orange by nitric acid, milky by the corrosive chloride of mercury, and has its own colour deepened by ammonia; but throws down no precipitate with either of these reagents. Sulphate of zinc is said by Dr. A. T. Thomson to occasion a slow precipitate, but this result was not obtained by Dr. Duncan.

Medical Properties and Uses. As might be inferred from the quantity of tannin they contain, galls are powerfully astringent. They are little employed as an internal remedy, though occasionally prescribed in chronic diarrhœa. In the form of infusion or decoction they may be advantageously used as an astringent gargle, lotion, or injection; and, mixed with simple ointment, in the proportion of one part of galls, in very fine powder, to eight parts of the unguent, they are frequently applied to the anus and rectum in hemorrhoidal affections. The dose of powdered galls is from ten to twenty grains, to be repeated several times a day.

GAMBOGIA. *U.S.*

Gamboge.

"Stalagmitis cambogioides. Succus concretus. *The concrete juice.*" *U.S.*

Off. Syn. CAMBOGIA. Stalagmitis Cambogioides. Gummi-resina. *Lond.;* GAMBOGIA. Gummi resina ex Stalagmitide Cambogioide et quibusdam aliis, *Ed.;* GAMBOGIA. STALAGMITIS CAMBOGIA. *Dub.*

Gomme gutte, *Fr.;* Gummigutt, *Germ.;* Gomma-gotta, *Ital.;* Guta gamba, *Span.*

Several plants belonging to the natural family of the *Guttiferæ*, growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure to the air, and bears a close resemblance to gamboge; but it is not certainly known from which of these plants the officinal gum-resin is procured. Persoon, De Candolle, Richard, and others, refer it to the *Garcinia Cambogia*—the *Cambogia Gutta* of Linnæus—while the majority of writers agree with Kœnig, in considering it the product of the *Stalagmitis Cambogioides* of Murray; and the latter is recognised by the American and all the British Pharmacopœias. Dr. White, who was well acquainted with the *Garcinia Cambogia*, asserts that its concrete juice is not the gamboge of commerce; and we are informed by Dr. Duncan, that a specimen of the yellow juice of the *Stalagmitis* which he received from India has not the properties of that drug. Ainslie states that a forest tree has been found in Malabar and Canara, which yields a juice in all respects identical with gamboge; but it has not been botanically described; and its product has not been brought into the market. On the whole, it must be admitted that we are uncertain, not only as to the precise tree which affords the officinal gamboge, but also whether it is derived from any one tree exclusively, or from several. In this uncertainty, it seems hardly necessary to crowd our pages with botanical descriptions, which may possibly have no relation to the subject.

Gamboge is collected in Siam and Cochin-china. It is said also to be produced in Ceylon, where the *Stalagmitis Cambogioides* grows; but it is doubtful whether any of the drug, as found in commerce, is derived from this island. Milburn does not mention it among the exports. The tree from which it is obtained in Siam has not been examined by any botanist. The mode of procuring it is to break off the leaves and young shoots, from which the juice issues in drops, and being received in suitable vessels gradually thickens, and at length becomes solid. When it has attained the requisite consistence it is rolled into cylinders, and wrapped in leaves. The juice is sometimes received into the hollow joints of the bamboo, which give it a cylindrical form; and as it contracts during the process of solidification, the cylinder is often hollow in the centre. The name *gummi gutta*, by which it is generally known on the continent of Europe, probably originated from the circumstance that the juice escapes from the plant by drops. The officinal title was undoubtedly derived from the province of Cambodia, in which the gum-resin is collected. It was first brought to Europe by the Dutch about the middle of the seventeenth century.

We import gamboge from Canton and Calcutta, whither it is carried by the native or resident merchants. There is no difference in the appearance or character of the drug as brought from these two ports—an evidence that it is originally derived from the same place.

Properties. It is usually in cylindrical rolls, from one to two inches in diameter, sometimes hollow in the centre, often folded double, or agglutinated in masses in which the original form is not always readily distinguishable. The pieces are sometimes flattened. They are externally striated, and of a dull orange colour, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, which slightly adheres to the surface. Gamboge is brittle, with a smooth, conchoidal, shining fracture; and the fragments are slightly translucent at their edges. The colour of the mass when broken is a uniform deep orange-yellow, which becomes a beautiful bright yellow in the powder, or when the surface is rubbed with water. From the brilliance of its colour, gamboge is highly esteemed as a pigment. In the inferior kinds the tint is duller and less uniform. It has no smell, and little taste; but after remaining a short time in the mouth produces an acrid sensation in the fauces. Its sp. gr. is 1.221. Exposed to heat it burns with a white flame, emitting much smoke, and leaving a light spongy charcoal. It is a gum-resin, and, unlike most other substances of the same class, contains no essential oil. In 100 parts of it Braconnot found 19.5 parts of gum, 0.5 of impurities, and 80 of a red, insipid, transparent resinous substance, becoming yellow by pulverization, and supposed to consist of resin united with a yellow colouring principle. John obtained 10.5 per cent. of gum, 89 of resin, and 0.5 of impurities. Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resinous matter is very slowly deposited. It is almost entirely dissolved by alcohol; and a golden yellow tincture results, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; but the solution when diluted with water deposites a yellow precipitate.

Medical Properties and Uses. Gamboge is a powerful, drastic, hydragogue cathartic, very apt to produce nausea and vomiting when given in the full dose. It is much employed in the treatment of dropsy attended with torpid bowels, generally in combination with the supertartrate of potassa or jalap. It is also prescribed in cases of obstinate constipation, and has frequently been found effectual in the expulsion of the tapeworm. It is often combined with other and milder cathartics, the action of which it promotes and accelerates, while its own is moderated. The full dose is from two to six grains, which in cases of tænia has been raised to ten or fifteen grains. As it is apt to occasion much sickness and griping, the best plan, under ordinary circumstances, is to give it in small doses repeated at short intervals till it operates. It may be given in pill or emulsion, or dissolved in an alkaline solution. The last method of administration has been recommended in dropsical complaints.

GAULTHERIA. *U. S.*

Partridge-berry.

"Gaultheria procumbens. Folia. *The leaves.*" *U. S.*

GAULTHERIA. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Ericeæ.

Gen. Ch. Calyx five-cleft, bibracteate at the base. *Corolla* ovate. *Capsule* five-celled, invested with the berried calyx. *Pursh.*

Gaultheria procumbens. Willd. *Sp. Plant.* ii. 616; Bigelow, *Am. Med. Bot.* ii. 27; Barton, *Med. Bot.* i. 171. This is a small, indigenous, shrubby, evergreen plant, with a long, creeping, horizontal root, which sends up at intervals one and sometimes two erect, slender, round, reddish stems. These are naked below, leafy at the summit, and usually less than a span in height. The leaves are ovate or obovate, acute, revolute at the edges with a few mucronate serratures, coriaceous, shining, bright green upon the upper surface, paler beneath, of unequal size, and supported irregularly on short red petioles. The flowers, of which not more than from three to five are usually found upon each stem, stand on curved, drooping, axillary peduncles. The calyx is white, five-toothed, and furnished at its base with two concave cordate bractes, which are by some authors described as an outer calyx. The corolla is white, ovate or urceolate, contracted at its mouth, and divided at its border into five small acute segments. The stamens consist of curved, plumose filaments, and oblong orange-coloured anthers, opening on the outside. The germ, which rests upon a ring having ten teeth alternating with the ten stamens, is roundish, depressed, and surmounted by an erect filiform style, terminating in an obtuse stigma. The fruit is a small, five-celled, many-seeded capsule, enclosed in a fleshy covering, formed by the enlarged calyx, and presenting the appearance of a bright scarlet berry.

The plant extends from Canada to Georgia, growing in large beds in mountainous tracts, or in dry barrens and sandy plains, beneath the shade of shrubs and trees, particularly of other evergreens, as the Kalmiæ and Rhododendra. It is abundant in the pine barrens of New Jersey. In different parts of the country it is known by the various names of *partridge-berry*, *deer-berry*, *tea-berry*, and *mountain tea.* The flowers appear from May to September, and the fruit ripens at corresponding periods. Though the leaves only are officinal, all parts of the plant are endowed with the peculiar flavour for which these are employed, and which is found in several other plants, particularly in the bark of the *Betula lenta* or sweet birch. The fruit possesses it in a high degree, and being at the same time sweetish, is much relished by some persons, and forms a favourite article of food with partridges, deer, and other wild animals.

To the very peculiar and agreeably aromatic odour and taste which belong to the whole plant, the leaves add a marked astringency, dependent on the presence of tannin. The aromatic properties reside in a volatile oil, which may be separated by distillation. (See *Oleum Gaultheriæ.*)

Medical Properties and Uses. Gaultheria has the usual stimulant operation of the aromatics, united with astringency; and may, therefore, be used with advantage in some forms of chronic diarrhœa. Like other substances of the same class, it has been employed as an emmenagogue, and with the view of increasing the secretion of milk; but its chief use is to impart an agreeable flavour to mixtures and other preparations. It may be conveniently administered in the form of infusion, which in some parts of the country is not unfrequently used at the table as a substitute for common tea. The oil, however, is more used in regular practice than the leaves. Instances of death are on record, resulting from the use of the oil, by mistake, in the quantity of about a fluidounce. On examination after death, strong marks of inflammation of the stomach were discovered. (*Journ. of Phil. Col. of Pharm.* vi. 290.)

GENTIANA. *U.S.*

Gentian.

"Gentiana lutea. Radix. *The root.*" *U. S.*

Off. Syn. GENTIANÆ RADIX. Gentiana lutea. Radix. *Lond.*; GENTIANÆ LUTEÆ RADIX. *Ed.*; GENTIANA LUTEA. Radix. *Dub.*

Gentiane jaune, *Fr.*; Rother Enzian, *Germ.*; Genziana, *Ital.*; Genciana, *Span.*

Gentiana. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Gentianeæ.

Gen. Ch. *Corolla* one-petalled. *Capsule* two-valved, one-celled, with two longitudinal receptacles. *Willd.*

This genus is not constant in the number of the stamens. Some species have five stamens and a five-cleft corolla; others have only four stamens and a four-cleft corolla; others again have more than five. But the plants have so strong an affinity in their general characters, and are so uniform in the structure of the fruit, that they continue to be associated together by botanists, notwithstanding the discrepancies alluded to.

Gentiana lutea. Willd. *Sp. Plant.* i. 1331; *Woodv. Med. Bot.* p. 273. t. 95. Yellow gentian is among the most remarkable of the species which compose this genus, both for its beauty, and its great comparative size. From its thick, long, branching, perennial root, an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, oval, acute, five-nerved leaves, of a bright green colour, and somewhate glaucous. The lower leaves, which spring from the root, are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow colour, peduncled, and placed in whorls at the axils of the upper leaves. The calyx is a membranous deciduous spathe; the corolla is rotate, and deeply divided into five lanceolate, acute segments.

This plant grows among the Appenines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe. Its root is the only part used in medicine.

Several other species of the genus possess analogous medicinal properties, and are used for similar purposes. The roots of the *G. biloba* of De Candolle, and *G. punctata* of Linnæus, are said to be frequently mingled with the officinal gentian, from which they are scarcely distinguishable. The *G. purpurea* of Linnæus is much used in Norway and Germany, where it grows, and is considered quite equal to the *G. lutea.* The *G. macrophylla* of Pallas is used in Siberia; the *G. Chirayita* of Roxburgh in Bengal; and one indigenous species, the *G. Catesbæi*, has found a place in the secondary catalogue of the U. S. Pharmacopœia.

Gentian is imported from Germany.

Properties. As found in our shops, it is in pieces of various dimensions and shape, usually of considerable length, consisting sometimes of longitudinal slices, sometimes of the root cut transversely, twisted, wrinkled externally, of a grayish-brown colour on the outside, yellowish or reddish within, and of a soft spongy texture. The odour is feeble, but decided and peculiar. The taste is slightly sweetish, and intensely bitter, without being nauseous. The powder is of a yellowish colour. Water and alcohol extract the taste and medical virtues of the root. Examined by MM. Henry and Caventou, it was found to contain, 1. a peculiar principle called *gentianin*, 2. a volatile odorous principle, 3. a substance identical with bird-lime (*glu*), 4. a greenish fixed oil, 5. a free organic acid, 6. uncrystallizable sugar, 7. gum, 8. yellow colouring matter, and 9. lignin. *Gentianin*, which is probably the chief active ingredient of the root, is a yellow, crystallizable, neutral principle, without smell, with the bitterness of gentian, very soluble in ether and alcohol, slightly soluble in cold water, more so in hot water, partly volatilizable by heat, partly decomposed, with the evolution of products which indicate the presence of nitrogen in its composition. It is obtained by macerating the root in ether, decanting and evaporating the ethereal tincture, treating the residue with alcohol of 0.83 which leaves behind a viscid substance dissolved by the ether (*glu*), evaporating the alcoholic solution, and treating the residue with dilute alcohol, which, leaving a green fixed oil, dissolves the gentianin, and upon evaporation yields it in a crystalline state, though still impure. To procure it pure, the alcoholic solution is to be evaporated to dryness, and the residue boiled with a little water and recently calcined magnesia, which neutralizes some free acid present, while the volatile odorous principle is driven off by the heat. If the mass be now dried and submitted to the action of ether, perfectly pure gentianin is dissolved, and is obtained in needle-shaped crystals upon the evaporation of the ether. When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence, probably, of the presence of its saccharine and mucilaginous principles. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter, and unpleasant to the smell, is much relished by the Swiss and Tyrolese.

Medical Properties and Uses. Gentian possesses, in a high degree, the tonic powers which characterize the simple bitters. It excites the appetite, invigorates the powers of digestion, moderately increases the temperature of the body and the force of the circulation, and acts in fact as a general corroborant of the system. In very large doses, however, it is apt to load and oppress the stomach, to irritate the bowels, and even to occasion nausea and vomiting. It has been known as a medicine from the highest antiquity, and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients; and it enters into most of the stomachic combinations employed in modern practice. It may be used in all cases of disease dependent on pure debility of the digestive organs, or requiring a general tonic impression. Dyspepsia, gout, amenorrhœa, hysteria, scrofula, intermittent fever, diarrhœa, worms, are among the many forms of disease in which it has proved useful; but it is the condition of the stomach and of the system generally, not the name of the disease, which must be taken into consideration in prescribing it, and there is scarcely a single complaint in which it can be advantageously administered under all circumstances. Its powder has been applied externally to malignant and sloughing ulcers. It is usually given in the form of infusion or tincture. The dose of the powder is from ten to forty grains.

Off. Prep. Extractum Gentianæ, *U.S., Lond., Ed., Dub.;* Infusum Gentianæ Compositum, *U.S., Lond., Ed., Dub.;* Tinctura Gentianæ, *U.S., Lond., Ed., Dub.;* Tinctura Rhei et Gentianæ, *U.S.;* Vinum Gentianæ Compositum, *U.S., Ed.* W.

GENTIANA CATESBÆI. *U.S. Secondary.*

Blue Gentian.

"Gentiana Catesbæi. Radix. *The root.*" *U.S.*

Gentiana. See GENTIANA.

Several indigenous species of gentian approach more or less nearly to the *Gentiana lutea* in the bitterness and medicinal virtues of their roots; but the *G. Catesbæi*, which resembles it most closely in these respects, is the only one which has attracted the particular attention of the medical profession.

Gentiana Catesbæi. Walter, *Flor. Car.* 109; Bigelow, *Med. Bot.* ii. 137; Nuttall, *Gen. of Am. Plants*, i. 172. The blue gentian has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite leaves, which are ovate lanceolate, acute, and rough on their margin. The flowers, which are of a palish-blue colour, are crowded, nearly sessile, axillary and terminal. The divisions of the calyx are linear lanceolate, and longer than the tube. The corolla is large, ventricose, plaited, and divided at its border into ten segments, of which the five outer are more or less acute, the five inner bifid and fringed. The number of stamens is five, and the two stigmas are seated on the germ. The capsule is oblong, acuminate, with two valves, and a single cell.

The *G. Catesbæi* grows in the grassy swamps of North and South Carolina, where it flowers from September to December. It was named by Walter and Elliott in honour of Catesby, by whom it was imperfectly delineated upwards of seventy years ago. Pursh confounds it with the *G. saponaria*, to which it is nearly allied.

Properties. By Dr. Bigelow we are told that the dried root of this plant has at first a mucilaginous and sweetish taste, which is soon succeeded by an intense bitterness, approaching nearly to that of the officinal gentian. Alcohol and boiling water extract its virtues, and the tincture and decoction are even more bitter than the root in substance. Blue gentian has not been satisfactorily analyzed.

Medical Properties. As a medicine it is little inferior to the European gentian, and may be employed for similar purposes. In the Northern and Middle States it is not used; but it is said to be occasionally prescribed by the practitioners of the South in dyspepsia, and other cases of stomachic and general debility. It may be given in powder in the dose of fifteen or thirty grains, and may be substituted for the foreign gentian in the preparation of the officinal extract, infusion, wine, and tincture. W.

GEOFFRÆÆ INERMIS CORTEX. *Ed.*

Cabbage-tree Bark.

Off. Syn. GEOFFROYA INERMIS. Cortex. *Dub.*

Geoffroya de Jamaique, *Fr.;* Jamaicanische Wurmrinde, *Germ.;* Geoffrœa, *Ital.*

GEOFFROYA. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ.

Gen. Ch. *Calyx* five-cleft. *Drupe* ovate. *Nucleus* compressed. *Willd.*

Several species have by some botanists been separated from the Geoffroya, and erected into a new genus with the title *Andira.* The distinctive character of the latter is a papilionaceous corolla and leguminous fruit, while in the true Geoffroya the corolla is not papilionaceous, and the fruit is a kind of drupe. The cabbage-tree is ranked among the *Andiræ.*

Geoffroya inermis. Willd. *Sp. Plant.* iii. 1130; Woodv. *Med. Bot.* p. 416. t. 151.—*Andira inermis*, Humb. and Bonp. *Nov. Gen. Amer.* The stem of this tree, which rises to a considerable height, is branched towards the top, and covered with a smooth gray bark. The leaves are pinnate, consisting of several pairs of lanceolate, pointed, veined, smooth, petiolate leaflets, with an odd one at the end. The flowers are rose-coloured, and appear in clusters upon large branched spikes. The cabbage-tree is a native of Jamaica and other West India islands. The bark is the part used.

On the continent of Europe the bark of the *G. Surinamensis*, the *Andira retusa* of Humb. and Bonp., which grows in Surinam, is also officinal. It is considered more powerfully vermifuge, without being equally liable to produce injurious effects.

Cabbage-tree bark is in long pieces, thick, fibrous, externally of a brownish-ash colour, scaly and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable smell, a sweetish, mucilaginous, bitterish taste, and affording a powder resembling that of jalap.

The bark of the *G. Surinamensis* has a grayish epidermis, beneath which it is reddish-brown, laminated, compact, very tenacious, and when cut transversely exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale cinnamon colour.

Medical Properties and Uses. Cabbage-tree bark is cathartic, and in large doses is apt to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water is drank during its operation, and are relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies the bark is esteemed a powerful vermifuge, and is much employed for expelling lumbrici; but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country, and does not enter into our officinal catalogues. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The dose of the powder is from a scruple to half a drachm, of the extract three grains, of the decoction two fluidounces.

GERANIUM. *U.S.*

Cranesbill.

"Geranium maculatum. Radix. *The root.*" *U.S.*

Geranium. *Sex. Syst.* Monadelphia Decandria.—*Nat. Ord.* Geraniaceæ.

Gen. Ch. *Calyx* five-leaved. *Corolla* five-petalled, regular. *Nectary* five melliferous glands united to the base of the longer filaments. *Arilli* five, one-seeded, awned, at the base of a beaked receptacle; awns simple, naked, neither spiral nor bearded. *Willd.*

Geranium maculatum. Willd. *Sp. Plant.* iii. 705; Bigelow, *Am. Med. Bot.* i. 84; Barton, *Med. Bot.* i. 149. This plant has a perennial, horizontal, fleshy root, which is furnished with short fibres, and sends up annually an herbaceous stem, with several radical leaves. The stem is erect, round, dichotomously branched, from one to two feet high, of a grayish-green colour, and thickly covered, in common with the petioles and peduncles, with reflexed hairs. The leaves are deeply divided into three, five, or seven lobes, which are variously incised at their extremities, hairy, and of a pale green colour, mottled with still paler spots. Those which rise immediately from the root are supported on footstalks eight or ten inches long; those of the stem are opposite, the lower petiolate, the upper nearly sessile, with lanceolate or linear stipules. The flowers are large, and usually of a purple colour. The peduncles spring from the forks of the stem, and severally support two flowers upon short pedicels. The calyx is composed of five oblong, ribbed, cuspidate leaves; the petals are five, obovate, and entire; the stamens ten, with oblong deciduous anthers, the five alternate filaments being longer than the others, and having glands at their base; the germ is ovate, supporting a straight style as long as the stamens, and surmounted by five stigmas. The fruit consists of five aggregate, one-seeded capsules, attached by a beak to the persistent style, curling up and scattering the seeds when ripe.

The cranesbill is indigenous, growing throughout the United States, in moist woods, thickets and hedges, and generally in low grounds. It flowers from May to July. The root should be collected in autumn.

This, when dried, is in pieces from one to three inches long, from a quarter to half an inch in thickness, somewhat flattened, contorted, wrinkled, tuberculated, and beset with slender fibres. It is externally of an umber-brown colour, internally reddish-gray, compact, inodorous, and of an astringent taste, without bitterness or other unpleasant flavour. Water and alcohol extract its virtues. Tannin is an abundant constituent.

Medical Properties and Uses. Geranium is one of our most powerful indigenous astringents, and may be employed for all the purposes to which these medicines are applicable. The absence of unpleasant taste and all other offensive qualities, renders it peculiarly serviceable in the cases of infants, or of persons with very delicate stomachs. Diarrhœa, chronic dysentery, cholera infantum in the latter stages, and the various hemorrhages, are the forms of disease in which it is most commonly used and with greatest advantage; but care should be taken, before it is administered, that the condition of the system and of the part affected is such as not to contra-indicate the use of astringents. As an application to indolent ulcers, an injection in gleet and leucorrhœa, a gargle in relaxation of the uvula and aphthous ulcerations of the throat, it answers the same purpose with kino, catechu, and other foreign remedies of similar character. It is a popular domestic remedy in various parts of the United States, and is said to be employed by the Indians in numerous disorders. It may be given in substance, decoction, tincture, or extract. The dose of the powder is twenty or thirty grains, that of a decoction made by boiling an ounce of the root in a pint and a half of water to a pint, from one to two fluidounces. The medicine is sometimes given to children boiled in milk. W.

GEUM. *U. S. Secondary.*

Water Avens.

"Geum rivale. Radix. *The root.*" *U. S.*

Benoite aquatique, *Fr.;* Wiesen-Benediktenwurzel, *Germ.*

GEUM. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx ten-cleft. *Petals* five. *Seeds* with a bent awn. *Willd.*

Several species belonging to this genus have been medicinally employed; but two only are deserving of particular notice, the *Geum rivale,* which has a place in the secondary list of the United States Pharmacopœia, and the *G. urbanum,* recognised by the Dublin College.

Geum rivale. Willd. *Sp. Plant.* ii. 1115; *Engl. Bot.* 106. The water avens has a perennial, horizontal, jointed, scaly, tapering root, about six inches long, of a reddish-brown colour externally, white internally, and furnished with numerous descending yellowish fibres. Sometimes one, sometimes several stems rise from the same root, which also sends up numerous leaves. The stems are about a foot and a half high, simple, erect, pubescent, and of a purplish colour. The radical leaves are interruptedly pinnate, with large terminal leaflets, and stand on long, hairy footstalks; those of the stem are petiolate, and divided into three serrate, pointed segments. The flowers are few, solitary, nodding, yellowish-purple, and supported on axillary and terminal peduncles. The colour of the stems and flowers has given rise to the name of *purple avens,* by which the plant is sometimes called. The calyx is inferior, with ten lanceolate pointed segments, of which the five alternate are smaller than the others. The petals are five, and of the same length as the calyx. The seeds are oval, and furnished with plumose awns, minutely uncinate, and nearly naked at the summit.

This species of Geum is common to Europe and the United States, though the plant of this country has smaller flowers, with petals more rounded on the top, and leaves more deeply incised than the European. It delights in wet boggy meadows, and extends from Canada into New England, New York, and Pennsylvania. Its flowers appear in June and July.

The dried root is hard, brittle, easily pulverized, of a reddish or purplish colour, without smell, and of an astringent, bitterish taste. Boiling water extracts its virtues.

Medical Properties and Uses. Water avens is tonic and powerfully astringent. It may be used with advantage in chronic or passive hemorrhages, leucorrhœa, and diarrhœa; and is said to be beneficially employed, in the Eastern States, as a popular remedy in the debility of phthisis pulmonalis, in simple dyspepsia, and in visceral diseases consequent on disorder of the stomach. In Europe it is sometimes substituted for the root of the *common avens,* or Geum urbanum, but is less esteemed. The dose of the powdered root is from a scruple to a drachm, to be repeated three times a day. The decoction, which is usually preferred, may be made by boiling an ounce of the root in a pint of water, and given in the quantity of one or two fluidounces. A weak decoction is sometimes used by invalids in New England as a substitute for tea and coffee. W.

GEUM URBANUM. Radix. *Dub.*

Root of Avens.

Benoite, *Fr.;* Benediktenwurzel, *Germ.;* Cariofillata, *Ital.;* Cariofilata, *Span.*

GEUM. See GEUM.

Geum urbanum. Willd. *Sp. Plant.* ii. 1113; Woodv. *Med. Bot.* p. 502. t. 181. Avens is an herbaceous perennial plant, with slender, erect, branching, hairy stems, about two feet in height. The leaves are petiolate, serrate, hairy; those on the upper part of the stem, simple, trifid, and pointed; those nearest the root, pinnate and lyrate, with two pairs of unequal leaflets, and a larger terminal leaflet, which is usually three-lobed. The flowers are small, of a bright yellow colour, and solitary upon erect terminal peduncles. The seeds, which are hairy and collected in a roundish head, have at their summit a naked awn, bent like a hook at the apex.

This species of Geum is a native of Europe, where it grows in woods and shady uncultivated places. The flowers appear in June and July. The root, which is the part employed, should be dug up in March, when its sensible properties are in greatest perfection, and should be dried by a moderate heat. The large roots are preferred to those which are very small, and the cultivated to the wild.

The avens root consists of a short oblong body or caudex, from a quarter to half an inch in thickness, externally brown, internally white towards the circumference and reddish at the centre, and sending forth numerous long brown descending fibres. When quite dry it is nearly inodorous, but in the recent state has a smell resembling that of cloves, whence it is sometimes called *radix caryophyllatæ.* Its taste is bitterish and astringent. It imparts its medicinal virtues to water and alcohol, which it tinges red. Distilled with water it yields a thick, greenish-yellow volatile oil, and gives a pleasant flavour to the liquid. Tannin is an abundant constituent. It contains, moreover, according to Trommsdorff, an insipid resin, gum, bassorin, and lignin.

Medical Properties and Uses. This root has been largely used on the continent of Europe as a tonic and astringent in numerous diseases. Among these are chronic and passive hemorrhages, chronic dysentery and diarrhœa, leucorrhœa, congestions of the abdominal viscera, and intermittent fever. The dose of the powdered root is from thirty grains to a drachm three or four times a day, and the same quantity may be given at a dose in the form of decoction. The medicine is scarcely used in the United States.

W

GILLENIA. *U.S.*

Gillenia.

"Gillenia trifoliata, *Bigelow* and *Barton.* Spiræa trifoliata, *Willd.* Radix. *The root.*" *U.S.*

Indian physic, American ipecacuanha.

Gillenia. *Sex. Syst.* Icosandria Pentagynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx tubular campanulate, border five-toothed. *Corolla* partly unequal. *Petals* five, lanceolate, attenuated at the base. *Stamens* few, included. *Styles* five. *Capsules* five, connate at the base, opening on the inner side, each two-seeded. *Torrey.*

This genus was separated by Moench from the *Spiræa*, but was not generally acknowledged till after the publication of Barton's Medical Botany. It is exclusively North American, and includes only two discovered species—the *G. trifoliata* and *G. stipulacea*—of which the former only has been adopted in our Pharmacopœia, though the two are identical in medical character.

1. *Gillenia trifoliata.* Bigelow, *Am. Med. Bot.* iii. 10; Barton, *Med. Bot.* i. 65. This is an herbaceous plant with a perennial root, consisting of numerous long, slender, brown branches, proceeding from a thick tuber-like head or caudex. The stems, several of which usually rise from the same root, are two or three feet in height, erect, slender, smooth, flexuose, branched, and commonly of a reddish colour. The leaves are ternate, with very short petioles, and small linear lanceolate stipules. The leaflets are ovate lanceolate, sharply serrate, and acuminate. The flowers grow in a loose terminal nodding panicle, with long peduncles. The calyx is tubular campanulate, ventricose, and terminates in five pointed segments. The corolla is composed of five linear lanceolate, recurved petals, the two upper separated from the three lower, white, with a reddish tinge on their border, and of three times the length of the calyx. The stamens are twenty, the filaments short, the anthers small and yellow. Each flower is succeeded by five capsules, connate at their base, oblong, acuminate, gibbous without, acute within, two-valved, one-celled, opening inward, and containing each one or two oblong seeds.

This species of Gillenia grows throughout the United States, east of the Alleghany ridge. Pursh found it in Florida, and it extends as far north as Canada. It frequents light soils, in shady and moist situations, and flowers in June and July. The root should be gathered in September.

2. *G. stipulacea.* Barton, *Med. Bot.* i. 71. This species is also herbaceous and perennial, though much taller, and more bushy than the preceding. The stems are brownish and branched. The upper leaves are ternate, lanceolate, serrate; the lower more deeply incised, becoming towards the root pinnatifid, and of a reddish-brown colour at the margin. The stipules are ovate, acuminate, deeply serrate, resembling leaves, and marking the species at the first glance. The flowers are smaller than those of the *G. trifoliata*, and grow on long slender peduncles in a lax corymb.

In the valley of the Mississippi this plant occupies the place of the G. trifoliata, which is not found beyond the Muskingum. It grows as far north as the state of New York, extends through Ohio, Indiana, Illinois, and Missouri, and probably into the states south of the Ohio, as it has been found in Western Virginia. Its root is precisely similar to that of the eastern species, and is reputed to possess the same properties.

The dried root of gillenia is not thicker than a small quill, wrinkled longitudinally, with occasional transverse fissures, and in the thicker pieces presenting in some places an irregular undulated somewhat knotty appearance, arising from indentations on one side corresponding with prominences on the other. It is externally of a light brown colour, and consists of a thick, somewhat reddish, brittle, cortical portion, with an interior slender, tougher, whitish ligneous cord. The bark, which is easily separable, has a bitter, not disagreeable taste; the wood is nearly insipid and comparatively inert, and should be rejected. The powder is of a light brownish colour, and possesses a feeble odour which is scarcely perceptible in the root. The bitterness is extracted by boiling water, which acquires the red colour of wine. The root has not been accurately analyzed.

Medical Properties and Uses. Gillenia is a mild and efficient emetic, and, like most other substances belonging to the same class, occasionally acts upon the bowels. In very small doses it has been thought to exert a tonic influence. It is much used by some practitioners in the country, as a substitute for ipecacuanha, which it is said to resemble in its mode of operation. It was employed by the Indians, and became known as an emetic to the colonists at an early period. Linnæus was aware of its reputed virtues. The dose of the powdered root is from twenty to thirty grains, repeated at intervals of twenty minutes till it vomits. W.

GLYCYRRHIZA. *U.S.*

Liquorice Root.

"Glycyrrhiza glabra. Radix. *The root.*" *U.S.*

Off. Syn. GLYCYRRHIZÆ RADIX. Glycyrrhiza glabra. Radix. *Lond.;* GLYCYRRHIZÆ GLABRÆ RADIX. *Ed.;* GLYCYRRHIZA GLABRA. Radix. *Dub.*

Bois de reglisse, *Fr.;* Süssholzwurzel, *Germ.;* Liquirizia, *Ital.;* Regaliza, *Span.*

GLYCYRRHIZA. *Sex. Syst.* Diadelphia Decandria.—*Nat. Ord.* Leguminosæ.

Gen. Ch. Calyx bilabiate; upper lip three-cleft, lower undivided. *Legume* ovate, compressed. *Willd.*

Glycyrrhiza glabra. Willd. *Sp. Plant.* iii. 1144; Woodv. *Med. Bot.* p. 420. t. 152. The liquorice plant has a perennial root, which is round, succulent, tough, and pliable, furnished with sparse fibres, rapid in its growth, and in a sandy soil penetrates deeply into the ground. The stems are herbaceous, erect, and usually four or five feet in height; have few branches; and are garnished with alternate, pinnate leaves, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale green colour, and clammy on their under surface. The flowers are violet or purple, formed like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to four small kidney-shaped seeds.

The plant is a native of the South of Europe, Barbary, Syria, and Persia; and is cultivated in England, the North of France, and Germany. Much of the root imported into this country comes from the ports of Messina and Palermo in Sicily. It is also largely produced in the northern provinces of Spain, where it forms an important article of commerce. It is not improbable that a portion of the liquorice root from Italy and Sicily is the product of the *G. echinata*, which grows wild in Apulia. This species is also abundantly produced in the South of Russia, where, according to Hayne, sufficient extract is prepared from it to supply the whole Russian empire.

A species of Glycyrrhiza, the *G. lepidota*, grows abundantly about St. Louis, in the state of Missouri, and flourishes along the banks of the Missouri river to its source in the mountains. It is probably the same with the liquorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Mr. Nuttall states that its root possesses in no inconsiderable degree the taste of liquorice; and it is not improbable that it may be found a fit substitute for that of the G. glabra.

Properties. The liquorice root of the shops is in long pieces, varying in thickness from a few lines to more than an inch, fibrous, externally grayish-brown and wrinkled by desiccation, internally yellowish, without smell, and of a sweet mucilaginous taste, which is sometimes mingled with a slight degree of acrimony. It is often worm-eaten and more or less decayed. The best pieces are those which have the brightest yellow colour internally, and of which the layers are distinct. The powder is of a grayish-yellow colour when the root is pulverized without being deprived of its epidermis, of a pale sulphur yellow, when the epidermis has been removed. Robiquet found the following ingredients in liquorice root:—1. A peculiar transparent yellow substance, called *glycyrrhizin*, of a sweet saccharine taste, scarcely soluble in cold water, very soluble in boiling water with which it gelatinizes on cooling, thrown down from its aqueous solution by acids, readily soluble in cold alcohol, insusceptible of the vinous fermentation, yielding no oxalic acid by the action of the nitric, and therefore wholly distinct from sugar; 2. a crystallizable principle, named *agedoïte* by Robiquet, but subsequently proved to be identical with *asparagin;* 3. starch; 4. albumen; 5. a brown, acrid resin; 6. a brown, azotized, extractive matter; 7. lignin; 8. salts of lime and magnesia with phosphoric, sulphuric, and malic acids. Robiquet prepared *glycyrrhizin* by subjecting a strong cold infusion of the root to ebullition, in order to separate the albumen; then filtering, precipitating with acetic acid, and washing the precipitate with cold water to remove any adhering acid. Berzelius considers the matter thus obtained as a compound of glycyrrhizin with acetic acid. He procures the principle in a pure state by precipitating with sulphuric acid an infusion of the root previously concentrated by a gentle heat, washing the precipitated sulphate to remove the free acid which adheres to it, then dissolving it in alcohol, which leaves the albumen, and adding carbonate of potassa to the alcoholic solution to perfect neutralization. The sulphate of potassa is precipitated, and the glycyrrhizin is obtained by evaporating the alcohol. The sweetness of this principle is retained in the compounds which it forms both with acids and alkalies.

An extract of liquorice root is brought from Spain and Italy, and much used under the name of liquorice. (See *Extractum Glycyrrhizæ.*)

Medical Properties and Uses. Liquorice root is an excellent demulcent, well adapted to catarrhal affections, and to irritations of the mucous membrane of the bowels and urinary passages. It is best given in the form of decoction, either alone, or combined with other demulcents. It is frequently employed as an addition to the decoctions of acrid or irritating vegetable substances, such for example as seneka and mezereon, the acrimony of which it covers and conceals, while it renders them more acceptable to the stomach. Before being used, it should always be deprived of its epidermis, which is somewhat acrid, without possessing any of the virtues of the root. The decoction may be prepared by boiling an ounce of the bruised root for a few minutes in a pint of water. By long boiling, the acrid principle is extracted.

The powder is used in the preparation of pills, either to give them due consistence, or to cover their surface and prevent them from adhering together.

GRANATUM. *U.S.*

Pomegranate.

"Punica granatum. Fructûs cortex. *The rind of the fruit.*" *U.S.*

Off. Syn. GRANATI CORTEX. Punica Granatum. Pomorum cortex. *Lond.;* PUNICA GRANATUM. Baccæ tunica exterior. Radicis cortex. Flores. *Dub.*

Ecorce de grenade, *Fr.;* Granatäpfel-Echalin, *Germ.;* Malicorio, Scorza del melogranati, *Ital.;* Corteza de granada, *Span.*

Punica. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. *Calyx* five-cleft, superior. *Petals* five. *Pome* many-celled, many-seeded. *Willd.*

Punica Granatum. Willd. *Sp. Plant.* ii. 981; Woodv. *Med. Bot.* p. 531. t. 190. The pomegranate is a small shrubby tree, attaining in favourable situations the height of twenty feet, with a very unequal trunk, and numerous branches, which sometimes bear thorns. The leaves are opposite, entire, oblong or lance-shaped, pointed at each end, smooth, shining, of a bright green colour, and placed on short footstalks. The flowers are large, of a rich scarlet colour, and stand at the end of the young branches. The petals are roundish and wrinkled, and are inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular berry, about the size of an orange, crowned with the calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many cells, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia, Persia, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher latitudes, where it does not bear fruit, it is raised in gardens and hot-houses for the beauty of its flowers, which become double, and acquire increased splendour of colouring by cultivation. Doubts have been entertained as to its original country. The name of "Punicum malum," applied by the ancients to its fruit, implies that it was abundant at an early age in the neighbourhood of Carthage. The fruit of the pomegranate, for which the plant is cultivated in tropical climates, varies much in size and flavour. It is said to attain greater perfection in both these respects in the West Indies, than in its native country. The pulp is red, succulent, pleasantly acid, and sweetish; and is used for the same purpose as the orange, though not officinal. It is the rind of the fruit which is indicated in the United States Pharmacopœia. Other parts of the plant, however, are used in medicine. The flowers, and the bark of the root have been adopted by the Dublin College, and the seeds are officinal in France.

Rind of the Fruit. This, which is the GRANATUM or *Pomegranate* of our Pharmacopœia, is presented in commerce under the form of irregular fragments, hard, dry, brittle, of a yellowish-brown colour, without smell, and of an astringent slightly bitter taste. It contains a large proportion of tannin, and in countries where the tree abounds, has been employed for tanning leather.

Flowers. The flowers, which are sometimes called *balaustines*, are inodorous, have a bitterish strongly astringent taste, and impart a violet-red colour to the saliva. They contain tannin and gallic acid, and were used by the ancients in dyeing.

Bark of the Root. The roots of the pomegranate are hard, heavy, knotty, ligneous, and covered with a bark which is yellowish-gray or ash-gray on the outer surface, and yellow on the inner. It has no smell, when chewed colours the saliva yellow, and leaves in the mouth an astringent taste, without any disagreeable bitterness. It contains, according to M. Mitouart, tannin, gallic acid, a substance analogous to wax, and a sweet substance of which one portion is soluble in alcohol and crystallizable, and another soluble in water with the characters of mannite. When used it should be entirely separated from the ligneous portion of the root, as the latter is inert.

Medical Properties and Uses. The rind of the fruit is astringent, and in the form of decoction may be given in diarrhœa from weakness of the secreting vessels, and in the colliquative sweats of hectic fever or simple debility. But the decoction is more frequently used as an injection in leucorrhœa, and as a gargle in sorethroat in the earliest stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in intermittent fever. The flowers have the same medical properties, and are used for the same purposes as the rind. The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna; but it was unknown in modern practice till brought into notice by Dr. F. Buchanan, who obtained his knowledge of its powers in India. The Mahometan physicians of Hindostan consider it a perfect specific in cases of tape-worm. One of these practitioners having speedily relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. Numerous cures have been subsequently effected in Europe; and there can be no doubt of the occasional efficacy of the remedy. The French medical writers prefer the bark of the root of the wild pomegranate, or that which grows on the borders of the Mediterranean, to the product of the imperfect tree cultivated for ornamental purposes in the gardens of colder countries. It may be administered in powder or decoction; but the latter form is usually preferred. M. Chevallier recommends the following mode of employing it. The patient is prepared by a dose of castor oil and a very strict regimen on the day preceding that on which the remedy is administered. A decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling down to a pint. Of this, one third is given every half hour. The first and second doses generally vomit; but the third remains. Within an hour after the administration of the last dose, the patient usually has three or four stools, in which the tænia is discharged. Should the bowels not be opened, an injection should be administered. Mr. Breton, who had great success with the remedy, administered it in a similar manner, and if he did not succeed on the first day, repeated the plan for four or five days successively, taking care, however, to omit the medicine when it produced vertigo, or pain in the bowels. He followed the decoction with a dose of castor oil. The remedy appears to have been used by the negroes of St. Domingo before it was introduced into Europe. Tænia is comparatively rare in this country; and the pomegranate root has been little used.

The dose of the rind and flowers in powder is from twenty to thirty grains. A decoction may be prepared in the proportion of one ounce of the medicine to a pint of water, and given in the dose of a fluidounce.

W.

GRATIOLÆ OFFICINALIS HERBA. *Ed.*

Hedge-hyssop.

Gratiole, *Fr.;* Wilder Aurin, *Germ.;* Graziola, *Ital.;* Graciola, *Span.*

Gratiola. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Scrophularineæ.

Gen. Ch. Corolla irregular, reversed. *Stamens*, two sterile. *Capsule* two-celled. *Calyx* seven-leaved; the two exterior leaves spreading. *Willd.*

Gratiola officinalis. Willd. *Sp. Plant.* i. 102; Woodv. *Med. Bot.* p. 360. t. 131. The hedge-hyssop is a perennial herb, with an erect quadrangular stem, about a foot in height, furnished with opposite, sessile, lanceolate, somewhat serrate leaves, and solitary, peduncled, axillary flowers. It is a native of the South of Europe, where it flourishes in meadows and other moist grounds. The whole herb is used.

It is nearly inodorous, but has a bitter nauseous taste. Both water and alcohol extract its active properties.

Medical Properties and Uses. Hedge-hyssop is a drastic cathartic and emetic, possessing also diuretic properties, and employed on the continent of Europe in dropsy, jaundice, worms, chronic hepatic affections, scrofula, and various other complaints. With us it is almost unknown as a remedy. The dose of the powdered herb is from fifteen to thirty grains; of the infusion, made in the proportion of half an ounce to the pint of boiling water, half a fluidounce. W.

GUAIACI LIGNUM. *U.S.*

Guaiacum Wood.

"Guaiacum officinale. Lignum. *The wood.*" *U.S.*

Off. Syn. GUAIACI LIGNUM. Guaiacum officinale. Lignum. *Lond.;* GUAIACI OFFICINALIS LIGNUM. *Ed.;* GUAIACUM OFFICINALE. Lignum. *Dub.*

Bois de gayac, *Fr.;* Pockenholz, *Germ.;* Legno guaiaco, *Ital.;* Guayaco, *Span.*

GUAIACUM. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Rutaceæ, *Juss.;* Zygophylleæ, *R. Brown, Lindley.*

Gen. Ch. Calyx five-cleft, unequal. *Petals* five, inserted into the calyx. *Capsule* angular, three or five-celled. *Willd.*

Guaiacum officinale. Willd. *Sp. Plant.* ii. 538; Woodv. *Med. Bot.* p. 557. t. 200. This is a large tree of very slow growth. When of full size it is from forty to sixty feet high, with a trunk four or five feet in circumference. The branches are knotted, and covered with an ash-coloured striated bark. That of the stem is of a dark gray colour, variegated with greenish or purplish spots. The leaves are opposite, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are obovate, veined, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue colour, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

The *G. officinale* grows in the West Indies, particularly in Hayti and Jamaica, and is found also in the warmer parts of the neighbouring continent. All parts of the tree are possessed of medicinal properties, but the wood and the concrete juice only are officinal. The bark, though much more efficacious than the wood, is not kept in the shops. It is said that other species of Guaiacum contribute to the supplies brought into the market. The *G. sanctum* of Linnæus, and the *G. arboreum* of De Candolle, are particularly specified. The former, however, is said by Woodville not to be sufficiently characterized as a distinct species from the *G. officinale.* Fée states that the wood of the *G. sanctum* is paler, less heavy and hard than the officinal.

Guaiacum wood is imported from Hayti and other West India islands, in the shape of logs or billets, covered with a thick gray bark, which presents on its inner surface, and upon its edges when broken, numerous shining crystalline points. These are supposed by M. Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant. These billets are used by the turners for the fabrication of various instruments and utensils, for which the wood is well adapted by its extreme hardness and density. It is kept by the druggists and apothecaries only in the state of shavings or raspings, which they obtain from the turners. It is commonly called *lignum vitæ*, a name which obviously originated from the supposition that the wood was possessed of extraordinary remedial powers.

Properties. The colour of the alburnum or sap-wood is yellow, that of the older and central layers greenish-brown, that of the shavings a mixture of the two. It is said that when the wood is brought into a state of minute division, the colour is rendered green by exposure to the air, (*Richard,*) and blueish-green by the action of nitric acid fumes; and the latter change may be considered as a test of the genuineness of the drug. (*Duncan.*) Guaiacum wood is almost without smell unless rubbed or heated, when it becomes odorous. When burnt it emits an agreeable aromatic odour. It is bitterish and slightly pungent; but requires to be chewed for some time before the taste is developed. Its medicinal properties are probably dependent on the guaiac with which it is impregnated. (See *Guaiacum.*) It yields its virtues but partially to water. One pound of the wood afforded to Geiger two ounces of extract.

Medical Properties and Uses. Guaiacum wood ranks among the stimulant diaphoretics. It is said to have been introduced to the notice of European practitioners by the natives of Hispaniola soon after the discovery of

America. It was used in Europe so early as 1508, and attained great celebrity as a remedy for lues venerea, in which it was long considered a specific. More extended experience, however, has proved it to be wholly inadequate to the cure of that disease; and it is now employed simply to palliate the secondary symptoms, to assist the operation of other and more efficient remedies, or to obviate the unpleasant effects sometimes resulting from a mercurial course in syphilitic cases. It is thought to be useful also in chronic rheumatism, scrofulous affections, certain cutaneous eruptions, ozæna, and other protracted diseases dependent on a depraved or vitiated condition of the system. It is always exhibited in decoction, and generally in combination with other medicines, as in the compound decoction of sarsaparilla. As but a small proportion of the guaiac which it contains is soluble in water, the probability is that its virtues have been greatly overrated; and that the good which has in many instances followed its employment, resulted rather from the more active medicines with which it was associated, or from the attendant regimen, than from the wood itself. The simple decoction may be prepared by boiling an ounce in a pint and a half of water down to a pint, the whole of which may be administered in divided doses during the twenty-four hours.

GUAIACUM. *U.S.*

Guaiac.

"Guaiacum officinale. Succus concretus. *The concrete juice.*" *U.S.*

Off. Syn. GUAIACI RESINA. Guaiacum officinale. Resina. *Lond.;* GUAIACI OFFICINALIS RESINA. *Ed.;* GUAIACUM OFFICINALE. Resina. *Dub.*

Résine de gayac, *Fr.;* Guajakharz, *Germ.;* Resina de guajaco, *Ital.;* Resina de guayaco, *Span.*

For a description of the *Guaiacum officinale*, see GUAIACI LIGNUM.

Guaiac is the concrete juice of this tree, obtained either by spontaneous exudation, or by incisions made into the trunk. It is also procured by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet in the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. Another mode, occasionally practised, is to boil the wood in the state of chips or saw-dust, in a solution of common salt, and skim off the matter which rises to the surface. Guaiac is brought to this market from the West Indies. It is usually in large irregular pieces of various size, in which small fragments of bark, sand, and other earthy impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes we find it in small roundish portions, separate, or agglutinated together, and evidently the result of exudation; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac, obtained from the billets of wood in the manner above described, is also of uniform consistence.

Properties. The pieces are of a deep greenish-brown or dark olive colour on their external surface, and internally wherever the air has been able to penetrate. The predominant hue of those parts not exposed to the air is reddish-brown or hyacynthine, diversified, however, with shades of various colours. The odour is feeble but fragrant, and is rendered stronger by heat. The taste which is at first scarcely perceptible, becomes acrid after a short period, and a permanent sense of heat and pungency is left in the mouth and fauces. Guaiac is brittle, and when broken presents a shining glass-like surface, conchoidal or splintery, with the smaller fragments more or less translucent. It is readily pulverized; and the powder, which is at first of a light gray colour, becomes green on exposure to the light. Its specific gravity varies from 1.2 to 1.23. It softens in the mouth, and melts with a moderate heat. Though commonly called *gum guaiac*, and till recently considered a gum-resin, it has been ascertained by Mr. Brande to be a substance sui generis, neither containing nor consisting of gum nor resin. In the Pharmacopœia of the United States, therefore, it is very properly designated by the simple title *Guaiacum.* Water dissolves 9 parts in 100, forming an infusion of a greenish-brown colour and sweetish taste, which upon evaporation yields a brown substance soluble in hot water and alcohol, but scarcely so in ether. Alcohol takes up 95 parts out of 100, leaving only impurities. The tincture is of a deep brown colour, is decomposed by water, and affords blue, green, and brown precipitates with the acids. Guaiac is soluble also in ether, in alkaline solutions, and in sulphuric acid. The solution in sulphuric acid is of a rich claret colour, deposites, when diluted with water, a lilac precipitate, and when heated evolves charcoal. Nitric acid converts it into oxalic acid. Exposed to air and light it absorbs oxygen and becomes green, and the change of colour takes place rapidly in the sunshine. It imparts a blue colour to gluten and substances containing it, to mucilage of gum Arabic, and to milk. It has been stated that *guaiac* is a substance *sui generis*; but as a part of it is soluble in water, and another part insoluble, it must consist of at least two proximate principles. The portion soluble in water, amounting to about one-tenth of the whole, is a kind of extractive; the remainder is a peculiar principle, which, though analogous to the resins, differs from this class of bodies in several particulars. It yields thirty per cent. of carbon, while the true resins yield only fifteen per cent.; is converted into oxalic acid, instead of artificial tannin, by nitric acid; and by the action of the same acid is made to pass through shades of green, blue, and brown, in this respect resembling indigo. These changes of colour are supposed to be owing to the absorption of different proportions of oxygen. The term *guaiacin*, which is applied by some writers to the whole concrete juice, and is therefore synonymous with the officinal title *Guaiacum*, should be restricted to the peculiar resin-like principle which constitutes by far the largest portion.

It will be inferred from what has been said, that the mineral acids are incompatible with the solutions of guaiac.

This drug is sometimes adulterated with the resin of the pine. The fraud may be detected by the terebinthinate odour exhaled when the sophisticated guaiac is thrown upon burning coals, as well as by its partial solubility in hot oil of turpentine. This liquid dissolves resin, but leaves pure guaiac untouched. Amber is said to be another adulteration. Nitric acid affords an excellent test of guaiac. If paper moistened with the tincture be exposed to the fumes of this acid, it speedily becomes blue.

Medical Properties and Uses. Guaiac is stimulant and alterative, producing, when swallowed, a sense of warmth in the stomach, with dryness of the mouth and thirst, and promoting various secretions. If given to a patient when covered warm in bed, especially if accompanied with opium and ipecacuanha or the antimonials, and assisted by warm drinks, it often excites profuse perspiration; and hence has been usually ranked among the diaphoretics. If the patient be kept cool during its administration, it is sometimes directed to the kidneys, the action of which it promotes. In large doses it purges; and it is thought by some practitioners to be possessed of emmenagogue powers. The complaint in which it has been found most beneficial is rheumatism. In the declining stages of the acute form of this disease, after due depletion, it is very often given in combination with opium, ipecacuanha, nitre, and the antimonials; and in the chronic form is frequently useful without accompaniment. It is also advantageously prescribed in gouty affections; and is occasionally used in secondary syphilis, scrofulous diseases, and cutaneous eruptions, though the guaiacum wood is more frequently resorted to in these latter complaints. Dr. Dewees places very great reliance upon it in the cure of amenorrhœa.

It is given in substance or tincture. The dose of the powder is from ten to thirty grains, which may be exhibited in pill or bolus, or in the shape of an emulsion formed with gum Arabic, sugar, and water. An objection to the form of powder is that it quickly aggregates. Guaiac is sometimes administered in combination with alkalies, with which it readily unites. Several of the European Pharmacopœias direct a soap of guaiac, under the name of *sapo guaiacinus*, to be prepared by diluting the Liquor Potassæ with twice its weight of water, boiling lightly, then adding guaiac gradually, with continued agitation, so long as it continues to be dissolved, and finally filtering, and evaporating to the pilular consistence. Of this preparation one scruple may be taken daily in divided doses.

Gen. Ch. *Calyx* five-parted. *Petals* five. *Capsule* lanceolate, one-celled, two-valved, with the valves boat-form. *Willd.*

Hæmatoxylon Campechianum. Willd. *Sp. Plant.* ii. 547; Woodv. *Med. Bot.* p. 455. t. 163. This is a tree of middle size, usually not more than twenty-four feet high, though under favourable circumstances it sometimes attains an elevation of forty or fifty feet. The trunk, which seldom exceeds twenty inches in diameter, is often very crooked, and is covered with a dark rough bark. The branches are also crooked, with numerous smaller ramifications, which are beset with sharp spines. The sap-wood is yellowish; but the interior layers are of a deep red colour. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obcordate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx, and lemon-yellow petals. They exhale an agreeable odour, said to resemble that of the jonquil.

The tree is a native of Campeachy, the shores of Honduras Bay, and other parts of tropical America; and has been introduced into Jamaica, where it has become naturalized. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs, deprived of the sapwood, and having a blackish-brown colour externally. For medical use it is cut into chips, or rasped into coarse powder, and in these states is kept in the shops.

Properties. Logwood is hard, compact, heavy, of a deep red colour becoming dark by exposure, of a slight peculiar odour, and a sweet somewhat astringent taste. It imparts its colour to water and to alcohol. The infusion made with cold water, though red, is less so than that with boiling water. It affords precipitates with sulphuric, muriatic, and acetic acids, with alum, sulphate of copper, acetate of lead, and sulphate of iron, striking a bluish-black colour with the last mentioned salt. (*Thomson's Dispensatory.*) Gelatin throws down a precipitate, which is redissolved by an excess of that principle. (*Duncan.*) Among the constituents of logwood, according to Chevreul, are a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin, another brown substance soluble in alcohol but insoluble in water or ether, an azotized substance resembling gluten, free acetic acid, various saline matters, and a peculiar azotized principle, called *hematin*, on which the colouring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture till it becomes thick, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hematin is deposited in the state of crystals, which may be purified by washing with alcohol and drying. They are shining, of a yellowish rose colour, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. Acids added gradually to the infusion render it at first yellow and afterwards red. Alkalies render it purple-red, but in great excess produce a violet-blue colour. Hematin unites with various metallic oxides, forming blueish compounds, and yields a flocculent reddish precipitate with a strong solution of glue.

Medical Properties and Uses. Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed cholera infantum. In this disease it is much used in the United States, and is also occasionally employed with advantage in ordinary chronic diarrhœa, and in chronic dysentery. It may be given in decoction or extract, both of which are officinal.

* * *

HEDEOMA. *U.S.*

Pennyroyal.

"Hedeoma pulegioides. Herba. *The herb.*" *U.S.*

This herb, first attached to the genus *Melissa*, and afterwards to *Cunila*, is at present universally considered by botanists as belonging to the *Hedeoma* of Persoon. It has been very erroneously confounded by some with the *Mentha Pulegium*, or European pennyroyal.

HEDEOMA. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Calyx* bilabiate, gibbous at the base, upper lip three toothed, lower two; dentures all subulate. *Corolla* ringent. *Stamens*, two sterile; the two fertile stamens about the length of the corolla. *Nuttall.*

Hedeoma Pulegioides. Barton, *Med. Bot.* ii. 165.—*Cunila Pulegioides.* Willd. *Sp. Plant.* i. 122. This is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent stem, which sends off numerous slender erect branches. The leaves are opposite, oblong lanceolate or oval, nearly acute, attenuated at the base, remotely serrate, rough or pubescent, and prominently veined on the under surface. The flowers are very small, of a pale blue colour, supported on short peduncles, and arranged in axillary whorls, along the whole length of the branches.

The plant is common in all parts of the United States, preferring dry grounds and pastures, and, where it is abundant, scenting the air for a considerable distance with its grateful odour.

Both in the recent and dried state it has a pleasant aromatic smell, and a warm, pungent, mint-like taste. It readily imparts its virtues to boiling water. The volatile oil upon which they depend may be separated by distillation, and employed instead of the herb itself.

Medical Properties and Uses. Pennyroyal is a gently stimulant aromatic, and may be given in flatulent colic and sick stomach, or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and of exciting the menstrual flux when the system is predisposed to the effort. Hence it is much used as an emmenagogue in popular practice, and frequently with success. A large draught of the warm tea is given at bed-time, in recent cases of suppression of the menses, the feet having been previously bathed in warm water.

HELLEBORUS FŒTIDUS. *U.S. Secondary.*

Bears'-foot.

"Helleborus fœtidus. Folia. *The leaves.*" *U.S.*

Off. Syn. HELLEBORI FŒTIDI FOLIA. *Lond.*

Ellébore fœtide, Pied de griffon, *Fr.;* Stinkende Niesswurzel, *Germ.;* Elleboro fetido, *Ital.;* Heleboro hediondo, *Span.*

HELLEBORUS. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* none. *Petals* five or more. *Nectaries* bilabiate, tubular. *Capsules* many-seeded, nearly erect. *Willd.*

Helleborus fœtidus. Willd. *Sp. Plant.* ii. 1337; Woodv. *Med. Bot.* p. 477. t. 170. This is a perennial European plant, with a stem about eighteen inches in height, naked and attenuated below, dividing into branches near the summit, and surrounded in the middle by numerous pedate leaves of a lurid green colour. Each leaf stands on a long footstalk, and usually consists of nine lance-shaped, serrated leaflets, four on each side joined together at their base, and one terminal. At each division of the flower-stem is a scaly leaf, three-cleft at the first ramification, then bifid, and at the last subdivisions, entire and pointed. The flowers are numerous, terminal, peduncled, and pendent; of a roundish form; with five pale green petals, tinged with purple at their margins. The whole plant, with the exception of the larger leaves, has a pale yellowish-green colour by which it may be distinguished at a distance.

The bear's foot grows in England under hedges and in shady places, and flowers in March and April. It derived its botanical designation from the offensive odour which it exhales. The leaves are the part used. Their taste is bitterish, pungent, and acrid; and when chewed they excoriate the mouth. The footstalks are even more acrid than the leaves themselves. The plant has not been analyzed.

Medical Properties and Uses. This species of hellebore is said by Allioni to be the most acrid and energetic of all the plants belonging to the genus. It is powerfully emetic and cathartic, and in very large doses produces dangerous effects. It has long been used in Great Britain as a domestic remedy for worms, and was brought before the notice of the profession by Dr. Bisset. This gentleman found it a very efficacious anthelmintic, and prescibed it also in asthma, hysteria, and hypochondriasis. M. Decerfs has known it to cause the expulsion of tænia. It is given in powder or decoction. The dose for a child from two to six years old is from five grains to a scruple of the dried leaves, or a fluidounce of the decoction made by boiling a drachm of the dried leaves in half a pint of water. This quantity should be repeated morning and night for two or three days in succession. A syrup made from the juice of the green leaves is also used in England. The remedy is scarcely known in the United States. W.

HELLEBORUS NIGER. *U.S.*

Black Hellebore.

"Helleborus niger. Radix. *The root.*" *U.S.*

Off. Syn. HELLEBORI NIGRI RADIX. *Lond.;* RADIX HELLEBORI NIGRI. *Ed.;* HELLEBORUS NIGER. Radix. *Dub.*

Ellébore noire, *Fr.;* Schwarze Niesswurzel, *Germ.;* Elleboro nero, *Ital.;* Heleboro negro, *Span.*

Helleborus. See HELLEBORUS FŒTIDUS.

Helleborus niger. Willd. *Sp. Plant.* ii. 1336; Woodv. *Med. Bot.* p. 473. t. 169. The root of the black hellebore is perennial, knotted, blackish on the outside, white within, and sends off numerous long, simple, depending fibres, which are brownish-yellow when fresh, but become dark brown upon drying. The leaves are pedate, of a deep green colour, and stand on long footstalks which spring immediately from the root. Each leaf is composed of five or more leaflets, one terminal, and two, three, or four on each side supported on a single partial petiole. The leaflets are ovate lanceolate, smooth, shining, coriaceous, and serrated in their upper portion. The flower-stem, which also rises from the root, is six or eight inches high, round, tapering, reddish towards the base, and bears one or two large, pendent, rose-like flowers, accompanied with floral leaves, which supply the place of the calyx. The petals, five in number, are large, roundish, concave, spreading, and of a white or pale rose colour, with occasionally a greenish tinge. There are two varieties of the plant—the *Helleborus* *niger humilifolius*, and *Helleborus niger altifolius*—in the former of which the leaves are shorter than the flower stem, in the latter longer.

This plant is a native of the mountainous regions of southern and temperate Europe. It is found in Greece, Austria, Italy, Switzerland, France, and Spain. It is cultivated in gardens for the beauty of its flowers, which expand in the middle of winter, and have, from this circumstance, given rise to the name of *Christmas rose*, by which the black hellebore is sometimes called.

Till the publication of Tournefort's travels in the Levant, this species of hellebore was regarded as identical with that so well known, under the same title, to the ancient Greeks and Romans. But in the island of Anticyra, and various parts of continental Greece, in which it appears from the testimony of ancient writers that the hellebore abounded, this traveller discovered a species entirely distinct from those before described, and particularly from the *H. niger*. He called it *H. orientalis*, and reasonably inferred that it was the true hellebore of the ancients: and botanists at present generally coincide with this opinion. But as the *H. niger* is also found in some parts of Greece, it is not impossible that the two species were indiscriminately employed. It is, indeed, highly probable that they possess similar properties; and a third—the *H. viridis*—which grows in the west of Europe, is said to be frequently substituted for the *H. niger*, which it closely resembles, if it does not equal in medicinal power. All three are recognised as officinal in the French Codex. The roots of various other plants not belonging to the same genus are said to be frequently substituted for the black hellebore. They may usually be readily distinguished by attending to the characters of the genuine root.*

The medicine of which we are treating is sometimes called *melampodium*, in honour of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of king Prætus by giving them the milk of goats which had been fed on hellebore.

Properties. Though the whole root is kept in the shops, the fibres are the portion usually recommended. They are about as thick as a straw, when not broken from four inches to a foot in length, smooth, brittle, externally black or deep brown, internally white or yellowish-white, with little smell, and a bitterish, nauseous, acrid taste. In their recent state they are extremely acrimonious, producing on the tongue a burning and benumbing impression like that which results from taking hot liquids into the mouth. This acrimony is diminished by drying, and still further impaired by age.

---

* The following minute description of the root, which we copy from Geiger's *Handbuch der Pharmacie*, may perhaps be useful in enabling the druggist to distinguish this from other analogous roots mingled with or substituted for it in commerce. "It is usually a many-headed root, with a caudex or body half an inch thick or less, seldom thicker, and several inches long, horizontal, sometimes variously contorted, uneven, knotty, with transverse ridges, slightly striated longitudinally, presenting on its upper surface the short remains of the leaf and flower-stalks, and thickly beset upon the sides and under surface with fibres of the thickness of a straw and from six to twelve inches long. These are undivided above, but at the distance of from two to six inches from their origin, are furnished with small, slender branches. The colour of the root is dark-brown, sometimes rather light-brown, dull, and for the most part exhibiting a gray, earthy tinge. Internally, it is whitish, with a somewhat darker pith, which, when cut transversely, shows lighter converging rays. Sometimes it is porous. It has a medullary or fleshy not a ligneous consistence. The fibres, when dried, are wrinkled, very brittle, sometimes grayish internally, horny, with a white point in the centre. The odour of the dried root is feeble, somewhat like that of seneka but more nauseous, especially when the root is rubbed with water. The taste is at first sweetish, then nauseously acrid and biting, but not very durable, and slightly bitterish." *Band.* ii. *s.* 1181.

MM. Feneulle and Capron obtained from black Hellebore, a volatile oil, an acrid fixed oil, a resinous substance, wax, a volatile acid, bitter extractive, gum, albumen, gallate of potassa, supergallate of lime, a salt of ammonia, and woody fibre. Water and alcohol extract its virtues, which are impaired by long boiling.

Medical Properties and Uses. Black hellebore is a drastic hydragogue cathartic, possessed also of emmenagogue powers, which by some are ascribed to a specific tendency to the uterus, by others are supposed to depend solely on the purgative property. In overdoses it produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The medicine was very highly esteemed by the ancients, who employed it in mania, melancholy, amenorrhœa, dropsy, epilepsy, various cutaneous affections, and verminose diseases. By the earlier modern physicians it was also much used. Bacher's pills, celebrated for the cure of dropsy, consisted chiefly of black hellebore. It is at present little employed, except as an emmenagogue, in which capacity it is very highly esteemed by some practitioners. Dr. Mead considered it superior to all other medicines belonging to this class. It may be given in substance, extract, decoction, or tincture. The dose of the powdered root is from ten to twenty grains as a drastic purge, two or three grains as an alterative. The decoction is prepared by boiling two drachms in a pint of water, of which a fluidounce may be given every four hours till it operates. The extract and tincture are officinal.

◆

HEPATICA. *U.S. Secondary.*

Liverwort.

"Hepatica Americana. Planta. *The plant.*" *U.S.*

HEPATICA. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ. *Gen. Ch. Calyx* three-leaved. *Petals* six to nine. *Seeds* naked. *Nuttall.*

Hepatica Americana. De Cand.; Eaton, *Man. of Bot.* p. 241.—*H. triloba.* Willd. *Enum.*; Figured in Rafinesque's *Med. Flor.* i. 238. Botanists generally admit but one species of Hepatica, the *H. triloba;* and consider as accidental the differences of structure and colour observable in the plant. Pursh speaks of two varieties, one with the lobes of the leaf oval and acute, the other with the lobes rounded and obtuse. These are considered as distinct species by De Candolle, and the latter is the one which has been adopted by the Pharmacopœia, and is popularly employed as a medicine in this country, under the name of *liverwort.* Both have a perennial fibrous root, with three-lobed leaves, cordate at their base, coriaceous, nearly smooth, of a green colour, sometimes mottled with purple on their upper surface, glaucous and purplish beneath, and supported upon hairy footstalks from four to eight inches long, which spring directly from the root. The scapes or flower-stems are several in number, of the same length with the petioles, round, hairy, and terminating in a single white, bluish, or purplish flower. The calyx is at a little distance below the corolla, and is considered by some an involucre, while the corolla takes the name of the calyx. In the *H. acutiloba* the leaves are cordate, with from three to five entire, acute lobes; and the leaflets of the calyx are acute. In the *H. Americana* the leaves are cordate-reniform, with three entire, roundish, obtuse lobes; and the leaflets of the calyx are obtuse. Both are indigenous, growing in woods upon the sides of hills and mountains, the former, according to Eaton, preferring the northern, the latter the southern exposure. The leaves resist the cold of the winter, and the flowers make their appearance early in spring. The whole plant is used.

It is without smell, and has a mucilaginous, somewhat astringent, slightly bitterish taste. Water extracts all its active properties.

Medical Properties and Uses. Liverwort is a very mild, demulcent tonic and astringent, supposed by some to possess diuretic and deobstruent virtues. It was formerly used to some extent in Europe in various complaints, especially in chronic hepatic affections; but has fallen into entire neglect. In this country, some years since, it attracted much attention as a remedy in hæmoptysis and chronic coughs, and acquired for a time great popular confidence. Its credit, however, has already begun to decline, and it will probably ere long be forgotten. It may be used in infusion and taken ad libitum. The term *liverwort* properly belongs to the cryptogamous genus *Marchantia.* W.

◆

HERACLEUM. *U.S. Secondary.*

Masterwort.

"Heracleum lanatum. Radix. *The root.*" *U.S.*

HERACLEUM. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. *Fruit* elliptical, emarginate, compressed, striated, margined. *Corolla* difform, inflexed, emarginate. *Involucre* caducous. *Willd.*

Heracleum lanatum. Michaux, *Flor. Boreal. Am.* i. 166. This is one of our largest indigenous umbelliferous plants. The root is perennial, sending up annually a hollow pubescent stem, from three to five feet high, and often more than an inch in thickness. The leaves are ternate, downy on their under surface, and supported on downy footstalks; the leaflets petiolate, roundish, cordate, and lobed. The flowers are white, in large umbels, and followed by orbicular seeds.

Like the European species this is sometimes called cow-parsnip. It grows in meadows and along fences or hedges, from Canada to Pennsylvania, and flowers in June.

The root, which is the officinal part, bears some resemblance to that of common parsley in appearance. It has a strong disagreeable odour, and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Dr. Bigelow considers the plant poisonous, and advises caution in its use, especially when it is gathered from a damp situation.

Medical Properties, &c. Masterwort appears to be somewhat stimulant and carminative, and was used successfully by Dr. Orne of Salem, Massachusetts, in cases of epilepsy, attended with flatulence and gastric disorder. He directed two or three drachms of the pulverized root to be taken daily, for a long time, and a strong infusion of the leaves to be drank at bed-time. (*Thatcher's Dispensatory.*) W.

Gen. Ch. *Calyx* five-cleft. *Petals* five, small. *Capsule* bi-rostrate, bilocular, many-seeded. *Nuttall.*

Heuchera Americana. Willd. *Sp. Plant.* i. 1328; Barton, *Med. Bot.* ii. 159.—*H. cortusa,* Michaux, *Flor. Boreal. Am.* i. 171.—*H. viscida,* Pursh, *Flor. Am. Sept.* p. 187. The *alum-root* or *American sanicle* is a perennial, herbaceous plant, the leaves of which are all radical, petiolate, cordate, with rounded lobes, furnished with obtuse mucronate teeth. There is no proper stem; but numerous scapes or flower-stems are sent up by the same root, from one to three feet in height, very hairy in their upper part, and terminating in long, loose, pyramidal, dichotomous panicles. The calyx is small, with obtuse segments; the petals lanceolate, rose-coloured, and of the same length with the calyx; the filaments much longer, yellowish, and surmounted by small, red, globose anthers. The whole plant is covered with a viscid pubescence.

It is found in shady, rocky situations, from New England to Carolina, and flowers in June and July. The root is the medicinal portion. It is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste.

Medical Properties. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. It has hitherto, however, been little used. We are informed in Dr. Barton's "Collections," that it is applied by the Indians to wounds and obstinate ulcers, and that it is the basis of a powder which, when the author wrote, enjoyed some reputation as a cure for cancer. W.

HIRUDO MEDICINALIS. *Dub.*

The Leech.

Sangsue, *Fr.;* Blutegel, *Germ.;* Mignatta, *Ital.;* Sanguijuela, *Span.*

Hirudo. *Class* 1, Annelides. *Order* 3, Abranchiatæ. *Family* 2, Asetigeræ. *Cuvier.*

The leech belongs to that class of invertebrated articulated animals called *Annelides.* This class contains the worms with red blood, having soft retractile bodies composed of numerous segments or rings, breathing generally by means of branchiæ, with a nervous system consisting in a double knotted cord, destitute of feet, and supplying their place by the contractile power of their segments or rings. The third order of this class—*Abranchiatæ*—comprehends those worms which have no apparent external organ of respiration. This order is again divided into two families, to the second of which—the *Asetigeræ*, or those not having setæ to enable them to crawl—the leech belongs.

It is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened discs, the hinder one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these discs or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the centre of the anterior disc, and is furnished with three cartilaginous lens-shaped jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine sharp teeth, and meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the inferior surface. The nervous system consists of a cord extending the whole length, furnished with numerous ganglions. The intestinal canal is straight and terminates in the anus, near the posterior disc. Although hermaphrodite, leeches mutually impregnate each other. They are oviparous, and the eggs, varying from six to fifteen, are contained in a sort of spongy, slimy coccoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnous moss, or in moistened earth, and is frequently transported in this manner to great distances by the dealers.

Savigny has divided the genus Hirudo of Linnæus into several genera. The true leech is the Sanguisuga of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points.

Several species are used for medicinal purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus; and the *Hirudo decora* of this country.

1. *Hirudo medicinalis*. Linn. *ed. Gmel.* I. 3095.—*Sanguisuga officinalis*. Savigny, *Mon. Hir. p.* 112, *t.* 5. *f.* 1. *The green leech.*—*Sanguisuga medicinalis*. Savigny, *Mon. Hir. p.* 114, *t.* 5. *f.* 2. *The gray leech.* Many of the best zoologists regard the *Sanguisuga officinalis and S. medicinalis* of Savigny as mere varieties. They are both marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tesselated with black spots. The colour of the back varies from a blackish to a grayish-green. The belly in the first variety is of a yellowish-green colour, free from spots, and bordered with longitudinal black stripes. In the second it is of a green colour, bordered and maculated with black. This leech varies from two to three or four inches in length. It inhabits marshes and running streams, and is found abundantly throughout Europe.

The great use made of leeches in the modern practice of medicine has occasioned them to become a considerable article of commerce. They are collected in Spain, France, Italy, and Germany, and carried in large numbers to London and Paris. They are also frequently brought to this country, as the practitioners in some of our large cities use only the foreign leech, although our own waters furnish an inexhaustible supply of this useful worm.

2. *Hirudo decora*. Say, *Major Long's Second Expedition*, ii. 268. The medicinal leech of America has been described by Say under the name of *Hirudo decora*, in the appendix to the Second Expedition of Major Long. Its back is of a deep pistachio green colour, with three longitudinal rows of

square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range of a light brownish-orange colour. The belly is of the same colour, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood.

The use of the indigenous leech is nearly restricted to the city of Philadelphia. The practitioners of New York and Boston depend for their supplies upon foreign countries, and leeching is seldom resorted to in the southern or western states. Those which are used in Philadelphia are generally brought from Bucks and Berks county in Pennsylvania, and occasionally from other parts of the state. It is estimated that from 200,000 to 250,000 are annually consumed.

The proper preservation of leeches is an object of importance to the practitioner, as they are liable to great and sudden mortality. They are usually kept in jars in clear water, which should be changed twice or three times a week. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time, and continue active and healthy, without any other attention than that of frequently changing the water in which they are kept. M. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed six or seven inches deep, of a mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them too much, or preventing the water from freely penetrating them. At one end of the trough, and about mid-way of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin, and is a principal cause of its disease and death.

Medical Uses. Leeches afford the least painful, and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation, or their great tenderness when inflamed, do not admit of the use of cups; and in the cases of infants, are, under all circumstances, preferable to this instrument They are indeed a powerful therapeutic agent, and give to the physician, in many instances, a control over disease which he could obtain in no other way. Their use is in great measure restricted to the treatment of local inflammations; and, as a general rule, they should not be resorted to until the force of the circulation has been diminished by bleeding from the arm, or in the natural progress of the complaint.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech does not bite readily, the skin should be moistened with a little blood, or milk and water. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. Leeches continue to draw blood until they are gorged, when they drop off. The quantity of blood which they will draw varies according to the part to which they are applied, and the degree of inflammation existing in it. In the loose and vascular textures they will abstract more than in those which are firm and compact, and more from an inflamed than a healthy part. As a general rule, our leechers apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. Leeches will continue to suck after their tails are cut off, which is sometimes done, although it is a barbarous practice. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off the same application will make them disgorge the blood they have swallowed. Some leechers draw the leeches from the tail to the head through their fingers, and thus squeeze out the blood, after which all that is necessary is to put them in clean water and change it frequently. Leeches which are gorged with blood should be kept in a vessel by themselves, as they are more subject to disease, and often occasion a great mortality among the others. They should not be again used until they have recovered their activity.

In cases where the bleeding from leech-bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, or by touching the wounds with lunar caustic.* It may sometimes be necessary, in the case of a deep bite, to sew the wound, which is readily done with a single stitch of the needle that need not penetrate deeper than the cutis. HORDEUM. *U.S.*

Barley.

"Hordeum distichon. Semina decorticata. *The seeds decorticated.*" *U.S.*

Off. Syn. HORDEI SEMINA. Hordeum distichon. Semina, tunicis nudata. *Lond.*; HORDEI DISTICHI SEMINA. Semina decorticata. *Ed.*; HORDEUM DISTICHON. Semina decorticata. *Dub.*

Orge, *Fr.*; Gerstengraupen, *Germ.*; Orzo, *Ital.*; Cebada, *Span.*

HORDEUM. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Gramineæ.

Gen. Ch. *Calyx* lateral, two valved, one-flowered, three-fold. *Willd.*

Several species of Hordeum are cultivated in different parts of the world. The most common are the *H. vulgare*, and the *H. distichon*, both of which have been introduced into the United States.

1. *Hordeum vulgare.* Willd. *Sp. Plant.* i. 472; Loudon's *Encyc. of Plants.* p. 73. The culm or stalk of common barley is from two to four feet in height, fistular, and furnished with alternate, sheathing, lanceolate, roughish, and pointed leaves. The flowers are all perfect, and arranged in a close terminal spike, the axis of which is dentate, and on each tooth supports three sessile flowers. The calyx or outer chaff has two valves. The corolla or inner chaff is also composed of two valves, of which the exterior is larger than the other, and terminates in a long rough, serrated awn or beard. The seeds are arranged in four rows.

2. *H. distichon.* Willd. *Sp. Plant.* i. 473; Loudon's *Encyc. of Plants*, p. 73. This species is distinguished by its flat spike or ear, which on each flat side has a double row of imperfect or male florets without beards, and on each edge, a single row of bearded perfect or hermaphrodite florets.

---

* A little cotton, impregnated with a saturated solution of alum, will sometimes be found an effectual application.

The seeds therefore are in two rows, as indicated by the specific name of the plant.

The original country of the cultivated barley is unknown. The plant has been found growing wild in Sicily, and various parts of the interior of Asia; but it may have been introduced into these places. The *H. vulgare* is said by Pursh to grow in some parts of the United States, apparently in a wild state. The seeds are used in various forms.

1. In their natural state they are oval, oblong, pointed at one end, obtuse at the other, marked with a longitudinal furrow, of a yellowish colour externally, white within, having a faint odour when in mass, and a mild sweetish taste. They contain, according to Proust, in 100 parts, 32 of starch, 3 of gluten, 5 of sugar, 4 of gum, 1 of yellow resin, and 55 of *hordein*, a principle closely analogous to lignin. Berzelius suggests that hordein may be an intimate mixture of vegetable fibre with gluten and starch, which are very difficultly separable as they exist in this grain. Einhoff found in 100 parts, 67.18 of starch, 5.21 of uncrystallizable sugar, 4.62 of gum, 3.52 of gluten, 1.15 of albumen, 0.24 of phosphate of lime, and 7.29 of vegetable fibre; the remainder being water and loss.

2. *Malt* consists of the seeds made to germinate by warmth and moisture, and then baked so as to deprive them of vitality. By this process the sugar, starch, and gum are increased at the expense of the *hordein*, as shown by the analysis of Proust, who found in 100 parts of malt, 56 of starch, 1 of gluten, 15 of sugar, 15 of gum, 1 of yellow resin, and only 12 of *hordein*. Berzelius attributes the diminution of the hordein to the separation, during germination, of the gluten or starch from the fibrous matter with which he supposes them to be associated in that substance. It is in the form of malt that barley is so largely consumed in the manufacture of malt liquors.

An interesting substance called *diastase* has recently been discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, and in the potato. It is found, however, only after these have undergone germination, of which process it appears to be a product. Germinated barley seldom contains it in larger proportion than two parts in a thousand. It is obtained by bruising freshly germinated barley, adding about half its weight of water, expressing strongly, treating the viscid liquid thus obtained with sufficient alcohol to destroy its viscidity, then separating the coagulated albumen, and adding a fresh portion of alcohol, which precipitates the diastase in an impure state. To render it pure, it must be redissolved as often as three times in water, and precipitated by alcohol. It is solid, white, tasteless, soluble in water and weak alcohol, but insoluble in the latter fluid in a concentrated state. Though without action upon gum and sugar, it has the extraordinary property, when mixed, in the proportion of only one part to 200, with starch suspended in water, and maintained at a temperature of about 160°, of converting this principle into dextrine and the sugar of grapes. The whole of the starch undergoes this change, with the exception of the teguments of the granules, amounting to about 4 parts in 1000.—(Thénard, *Traité de Chim.* 6me ed. iv. 603.)

3. *Hulled barley* is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18.75 parts in the hundred.

4. *Barley meal* is formed by grinding the seeds previously deprived of their husk. It has a grayish-white colour, and contains, according to Fourcroy and Vauquelin, an oleaginous substance, sugar, starch, azotized matter, acetic acid, phosphate of lime and magnesia, silica, and iron. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

5. *Pearl barley—hordeum perlatum*—is the seed deprived of all its investments, and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper officinal form of barley, and is kept in the shops almost to the exclusion of the others.

Medical Properties. Barley is one of the mildest and least irritating of farinaceous substances; and, though not medically used in its solid state, forms by decoction with water, a drink admirably adapted to febrile and inflammatory complaints, and much employed from the times of Hippocrates and Galen to the present. Pearl barley is the form usually preferred for the preparation of the decoction, though the hulled grain is sometimes used, and malt affords a liquor more demulcent and nutritious, and therefore better adapted to cases of disease which require a supporting treatment. (See *Decoctum Hordei.*) The decoction of malt may be prepared by boiling from two to four ounces in a quart of water and straining the liquor. When hops are added, the decoction takes the name of wort, and acquires tonic properties, which render it useful in debilitated conditions of the system, especially those which attend the suppurative process.

Gen.Ch. MALE. *Calyx* five-leaved. *Corolla* none. FEMALE. *Calyx* one-leafed, obliquely spreading, entire. *Corolla* none. *Styles* two. *Seed* one, within a leafy calyx. *Willd.*

Humulus Lupulus. Willd. *Sp. Plant.* iv. 769; Bigelow, *Am. Med. Bot.* iii. 163. The root of the hop is perennial, and sends up numerous annual, angular, rough, flexible stems, which twine around neighbouring objects in a spiral direction, from left to right, and climb to a great height. The leaves are opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green colour on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two or four smooth, ovate, reflexed stipules. The flowers are numerous, axillary, and furnished with bractes. The male flowers are yellowish-white, and arranged in panicles; the female, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears near its base, on its inner surface, two flowers, consisting of a roundish compressed germ, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain each at their base two small seeds, surrounded by a yellow, granular, resinous powder.

The hop is a native of North America and Europe. It is occasionally found growing wild in the Eastern States, and, according to Mr. Nuttall, is abundant on the banks of the Mississippi and Missouri. In New England it is extensively cultivated, and most of the hops consumed in the United States, are supplied by that district of country. The part of the plant used, as well in the preparation of malt liquors as in medicine, is the fruit or strobiles. These when fully ripe are picked from the vine, dried by artificial heat, packed in bales, and sent into the market, under the name of hops.

They consist of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow colour, and contain near their base two small, round, black seeds. Though brittle when quite dry, they are pulverized with great difficulty. Their odour is strong, peculiar, somewhat narcotic and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction; but the first mentioned property is dissipated by long boiling. The most active part of hops is a substance secreted by the scales, and in the dried fruit existing upon their surface in the form of a fine powder. This substance was called *lupulin* by Dr. A. W. Ives, of New York, by whom its properties were first investigated, and made generally known; though it appears to have been previously noticed by Sir J. E. Smith of England, and M. Planche of France. It enters into the officinal catalogue of the United States Pharmacopœia. The scales themselves, however, are not destitute of virtues, and contain, as shown by MM. Payen and Chevallier, the same active principles as the powder upon their surface, though in smaller proportion.

LUPULINA. *Lupulin, U.S.* This is obtained separate by rubbing or threshing and sifting the strobiles, of which it constitutes from one sixth to one-tenth by weight. It is in the state of a fine yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavour of hops, and appeared to MM. Lebaillif and Raspail, when examined by the microscope, to consist of globules filled with a yellow matter, resembling in this respect the pollen of vegetables. It is inflammable, and when moderately heated becomes somewhat adhesive. MM. Chevallier and Payen obtained from 200 parts, 105 of resin, and 25 of a peculiar bitter principle, besides volatile oil, gum, traces of fixed oil, a small quantity of an azotized substance, and various salts. Dr. Ives found in 120 grains, 5 of tannin, 10 of extractive, 11 of bitter principle, 12 of wax, 36 of resin, and 46 of lignin. The virtues of the powder probably reside in the volatile oil and bitter principle, and are readily imparted to alcohol. By boiling in water the bitterness is extracted, but the aroma is partially driven off.

It has been proposed, with reason, to restrict the name *lupulin* to the bitter substance discovered both in the powder and the scales, as this is in all probability the peculiar active principle of the plant. In a state of purity, it is yellowish or orange-yellow, inodorous at common temperatures, but of the smell of hops when heated, of the peculiar bitter taste of hops, slightly soluble in water which takes up five per cent. of its weight, readily soluble in alcohol, almost insoluble in ether, neither acid nor alkaline in its reaction, and without nitrogen in its composition. It is scarcely affected by the weak acids or alkaline solutions, or by the metallic salts.

Medical Properties and Uses. Hops are tonic and moderately narcotic, and have been highly recommended in diseases of general or local debility, associated with morbid vigilance, or other nervous derangement. They have some tendency to produce sleep and relieve pain, and may be used for these purposes in cases where opiates, from their tendency to constipate, or other cause, are inadmissible. Diuretic properties have also been ascribed to them, but are by no means very obvious. The complaints in which they have been found most useful are dyspepsia, and the nervous tremors, wakefulness, and delirium of drunkards. Dr. Maton found the extract advantageous in allaying the pain of articular rheumatism.

The medicine may be given in substance, infusion, tincture, or extract. From three to twenty grains are mentioned as the dose of the powder; but the quantity is too small to produce any decided effect; and this mode of administration is in fact scarcely ever resorted to. An infusion prepared from half an ounce of hops and a pint of boiling water, may be given in the dose of two fluidounces three or four times a day. The extract and tincture are officinal. (See *Extractum Humuli* and *Tinctura Humuli.*) A pillow of hops has been found useful in allaying restlessness and producing sleep, in cases of nervous derangement. They should be moistened with some spirituous liquor previously to being placed under the head of the patient, in order to prevent their rustling noise. Fomentations with hops, and cataplasms made by mixing them with some emollient adhesive substance, are often beneficial in local pains and tumefaction. An ointment of the powder with lard is recommended by Mr. Freake as an application to cancerous sores, the pain of which it has relieved when other means have failed.

All the effects of the preparations of hops may be obtained with greater certainty and convenience by the use of *lupulin.* The dose of this in substance is from six to twelve grains, given in the form of pills, which may be made by simply rubbing the powder in a warm mortar till it acquires the consistence of a ductile mass, and then moulding it into the proper shape. A tincture is directed by the United States Pharmacopœia. (See *Tinctura Lupulinæ.*) Lupulin may be incorporated with poultices, or formed into an ointment with lard, and used externally for the same purposes as the hops themselves.

HYDRARGYRUM. *U.S., Lond., Dub.*

Mercury.

Off. Syn. HYDRARGYRUS. *Ed.*

Quicksilver; Mercurius, *Lat.;* Mercure, Vif argent, *Fr.;* Quecksilber, *Germ.;* Mercurio, *Ital.;* Azógue, *Span.* and *Port.*

This metal is found native, combined with sulphur, united with silver, and in the form of chloride; but of all its combinations, the most abundant is the sulphuret, or native cinnabar. Its most important mines are found at Almaden in Spain, at Idria in Austria, in the Duchy of Deux Ponts, at Durasno in Mexico, near Azogue in New Granada, and near Huancavelica in Peru. It also occurs in the Philippine Islands and China. The most ancient and productive mine of mercury is that of Almaden, which is estimated to furnish six thousand quintals annually to commerce. Mercury in small quantities is said to have been found in the United States, in Ohio and Michigan Territory. (*Cleveland.*)

Extraction. Nearly all the mercury consumed in medicine and the arts, is obtained from the sulphuret or native cinnabar. It is extracted by two principal processes. According to one process the mineral is picked, pounded, and mixed with slaked lime. The mixture is then introduced into cast iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers, one-third full of water. Heat being applied, the lime combines with the sulphur, forming sulphuret of calcium and sulphate of lime, while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace underneath. At the upper and lateral part of the furnace, holes are made, which communicate with several rows of *aludels*,* which terminate in a small chamber that serves both as condenser and receiver. The mineral having been picked by hand and pulverized, is kneaded with clay and formed into small masses which are placed on the floor of the furnace. The heat being applied, the sulphur undergoes combustion, while the mercury, being volatilized, passes through the aludels to be condensed in the chamber. This process economizes fuel, but is wasteful of the mercury. A quintal of mineral yields from six to ten ounces of the metal.

Commercial History. Mercury is imported into this country generally in cylindrical iron bottles, called flasks, each containing 76½ pounds, and comes principally from the Atlantic ports of Spain, particularly Cadiz. A considerable portion also is received from the Austrian port of Trieste, from which it generally comes tied up in whole skins of white leather, forming bags, each containing 31 pounds, and four of which are usually packed together with straw in a rough flattened keg. In both Spain and Austria, the produce of the quicksilver mines is a government monopoly. In Spain all the metal is brought from the mines to Seville, whence, after paying an export duty, it is carried by small vessels down the river Guadalquivir to Cadiz and Gibraltar, which are the chief places of its depot for foreign commerce. The quantity imported into the United States varies in different years; but it appears by the Treasury returns that its value for the year ending in Sep. 1832, exceeded two hundred and sixty-three thousand dollars. A small portion of this only is consumed with us, the rest being exported principally to Mexico, Chili, and China. Its principal consumption is caused by its employment in the extraction of silver and gold from its ores, and in the preparation of vermilion. In the United States it is consumed for making thermometers and barometers, for silvering looking-glasses, and for preparing various pharmaceutical compounds. Of late the home consumption has increased in consequence of its employment in the mining operations of the gold region of the Southern States.

Properties. Mercury is a very brilliant liquid, of a silver-white colour, and without taste or smell. When perfectly pure it undergoes no alteration by the action of air or water, but, in its ordinary state, suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and becomes converted into peroxide; but at the temperature of ebullition, it parts with the oxygen which it had absorbed, and is reduced again to the metallic state. Its sp. gr. is 13.5, and its equivalent number 202. Liquid at ordinary temperatures, it freezes at 39° below zero, and boils at 656°. When frozen, it forms a soft malleable solid. It is a good conductor of caloric and its specific heat is small. It is not attacked by muriatic acid, nor by cold sulphuric acid; but boiling sulphuric acid, or cold nitric acid dissolves it, generating either a persulphate or pernitrate, with the extrication, in the former case, of sulphurous acid, in the latter of nitric oxide becoming nitrous acid red fumes. Its combinations are numerous, and several of them constitute important medicines. It forms two oxides, two sulphurets, two chlorides, and one cyanuret, all of which are used in medicine or pharmacy, and will be noticed elsewhere under separate heads. Both the oxides are capable of uniting with acids so as to form salts, of which the nitrate, sulphate, bisulphate, and acetate of the peroxide are officinal, or enter into officinal combinations.

---

* Aludels are a kind of pot, open at both ends, and which admit of being adjusted to one another, so as to form a sort of tube.

Mercury, as it occurs in commerce, is generally very pure; though occasionally it contains foreign metals, such as lead, bismuth, and tin. Mr. Brande informs us that in examining large quantities of this metal in the London market, he found it only in one instance intentionally adulterated. That which comes to the United States is also very pure. When impure, the metal has a dull appearance, easily tarnishes, is deficient in due fluidity and mobility, and when shaken in a phial soils or adheres to the glass. If agitated with dilute sulphuric acid, the adulterating metals become rapidly oxidized, and in this manner the mercury may in part be purified. Lead is detected by shaking the suspected metal with equal parts of acetic acid and water, and then testing the acid by sulphate of soda, or iodide of potassium. The former will produce a white, the latter a yellow precipitate, if lead be present. Bismuth is discovered by dropping a nitric solution of the mercury, prepared without heat, into distilled water, when the subnitrate of bismuth will precipitate; and the presence of tin is shown by adding to the nitric solution, diluted with water, a few drops of muriate of gold, which will cause a purple precipitate, the purple powder of Cassius.

Mercury may be purified, according to Berzelius, by digesting it with a small portion of nitric acid, or with a solution of bichloride of mercury (corrosive sublimate); whereby all the ordinary contaminating metals will be removed. This metal, however, is usually purified by distillation; and it is directed in the Pharmacopœias to be distilled for pharmaceutical use. (See *Hydrargyrum Purificatum.*)

Medical Properties. Mercury, in its uncombined state, is deemed inert; but in a state of combination, it acts on the living system as a peculiar and universal stimulant. Its combinations exhibit certain general medical properties and effects, which belong to the whole as a class; while each individual preparation is characterized by some peculiarity in its operation. Our business, in the present place, is to consider generally the physiological action of mercury, and the principles by which its administration should be regulated; while its effects, as modified in its different combinations, will more properly be noticed under the head of each preparation individually.

Of the modus operandi of mercury, we know nothing except that it probably acts through the medium of the circulation, and that it possesses a peculiar alterative power over the vital functions, which enables it in many cases to subvert diseased actions by substituting its own in their stead. This alterative power is sometimes exerted, without being attended with any other vital phenomenon than the removal of the disease; while at other times it is attended with certain obvious effects, indicative of the agency of a potent stimulus. In the latter case, its operation is marked by a quickened circulation, with a frequent, jerking pulse; by an increased activity imparted to all the secretory functions, particularly those of the salivary glands and the liver; by an exaltation of nervous sensibility; and, in short, by a general excitement of the organic actions of the system. When its effects are no otherwise obvious than in the subversion of disease, its operation, though so slight and imperceptible as altogether to escape notice, may be presumed to be the same as when it produces obviously stimulating effects.

When mercury acts insensibly as an alterative, there is not the least apparent disturbance of the circulation; but when it operates decidedly and obviously, it is very prone to let the brunt of its action fall upon the salivary glands, causing, in many instances, an immoderate flow of saliva, and constituting the condition denominated ptyalism or salivation. Under these circumstances, to the alterative effects of the mineral, are added those of depletion and revulsion. Occasionally its depletory action is exhibited in an increased secretion of urine, or an immoderate flow of the bile; and where ptyalism cannot be induced, and either of these secretions becomes considerably augmented, the circumstance may be held as equally conclusive of the constitutional impression of the mercury, as if the mouth had been affected.

Mercury has been used in almost all diseases, but too often empyrically, and without the guidance of any recognised therapeutic principle. Nevertheless, its efficacy in certain classes of diseases is universally acknowledged. In functional derangement of the digestive organs, mercurials in minute doses exert a salutary operation, subverting the morbid action, and that too by its insensible alterative effect, without affecting the mouth. In these cases no decided disturbance of the vital functions takes place; but the alvine discharges, if clay-coloured, are generally restored to their natural hue, a certain proof that the remedy is stimulating the liver, and promoting the secretion of the bile. Indeed there is no fact better established in medicine, than that of the influence of the mercurial preparations over the hepatic system; and whether the liver be torpid and obstructed as in jaundice, or pouring out a redundancy of morbid bile as in melæna, its judicious use seems equally efficacious in unloading the viscus, and restoring its secretion to a healthy state. In the acute and chronic hepatitis of India it is considered almost a specific; but here its use must be generally preceded by bleeding, and carried to the extent of exciting ptyalism. In chronic inflammation of the mucous and serous membranes, when accompanied by a feeble condition of the system, the alterative effects of mercury, are sometimes attended with much benefit. In many of these cases effusion has taken place; and under these circumstances the mercury often proves useful, by promoting the absorption of the effused fluid, as well as by removing the chronic inflammation on which its effusion depends. Hence it is that the remedy is often given with advantage in chronic forms of meningitis, bronchitis, pleuritis, pneumonia, dysentery, rheumatism, &c., and in hydrocephalus, hydrothorax, ascites, and general dropsy.

Mercury may also be advantageously resorted to in certain states of febrile disease. In some forms of the remittent fever of our own country, a particular stage of its course is marked by a dry tongue, torpor of the bowels, scanty urine, and an arid state of the surface. Here depletion by the lancet or leeches is often inadmissible, and the remedial measure most to be depended on is the judicious employment of mercury. It acts in such cases by increasing the secretions, and promoting the action of the exhalent capillaries, and, perhaps, by producing a new impression, incompatible with the action of the disease.

In syphilitic affections, mercury has been held to be, until of late years, an indispensable specific. Of its mode of action in these affections we know nothing, except that it operates by substituting its own peculiar action for that of the disease. Without entering upon the question of the necessity or non-necessity of mercury in venereal complaints, as out of place in this work, we are free to admit that the discussion which has grown out of it has shown that this remedy has sometimes been unnecessarily resorted to in affections resembling syphilis, though of a different character; and that the disease in question ought to be treated less empyrically, and more on the general principles of combating morbid action occurring in other parts. Mercury also appears to exert a peculiar control over the morbid effects of lead; and hence in colica pictonum, it is accounted by most writers to act almost as a specific.

For inducing the specific effects of mercury on the constitution, blue pill or calomel is generally resorted to. For producing what we have called the insensible alterative effects of the metal, a grain or two of blue pill may be given in the twenty-four hours, or from a sixth to a fourth of a grain of calomel; or if a gentle ptyalism be our object, from three to five grains of the former, or a grain of the latter, two or three times a day. Where the bowels are peculiarly irritable, it is often necessary to introduce the metal by means of frictions with mercurial ointment; and where a speedy effect is desired, the internal and external use of the remedy may be simultaneously resorted to.

The first observable effects of mercury in inducing ptyalism are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable smell, called the mercurial fetor. The saliva at the same time begins to flow; and if the affection proceeds, the gums, tongue, throat, and face are much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur; and the saliva flows in streams from the mouth. It occasionally happens, that the affection thus induced in the mouth proceeds to a dangerous extent, inducing extensive ulceration, gangrene, and even hemorrhage; when it will demand the attention of the practitioner. The best remedies are the various astringent and detergent gargles, used sufficiently weak, as the parts are in a state of extreme susceptibility. In cases attended with swelling and protrusion of the tongue, the wash is best applied by injection, by means of a large syringe. We have found lead-water among the best local applications in these cases; and dilute solutions of chloride of soda or of lime, while they correct the fetor and add to the comfort of the patient, will be found to exert a curative influence on the ulcerated surfaces.

In the foregoing observations we have described the ordinary effects of mercury; but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions. Mr. Pearson of London has given a detailed account of this occasional peculiarity in the operation of mercury in his work on the venereal disease. The symptoms which characterize it are a small frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming general debility. Their appearance is the signal for discontinuing the mercury; as a further perseverance with it might be attended with fatal consequences. Mercury is also productive of a peculiar eruption on the skin, which will be found described by the systematic writers under the various names of *hydrargyria*, *eczema mercuriale*, and *lepra mercurialis*.

Pharmaceutical Preparations. We shall close our account of mercury by presenting a tabular view of all the preparations containing this metal, to be found in the United States and British Pharmacopœias. Mercury is officinal,—

HYOSCYAMUS. *U. S.*

Henbane.

"Hyoscyamus niger. Folia. *The leaves.*" *U.S.*

Off. Syn. HYOSCYAMI FOLIA ET SEMINA. Hyoscyamus niger. Folia et semina. *Lond.;* HYOSCYAMI NIGRI HERBA. *Ed.*; HYOSCYAMUS NIGER. Folia. *Dub.*

Jusquiame noire, *Fr.;* Schwarzes Bilsenkraut, *Germ.;* Giusquiamo nero, *Ital.;* Beleno, *Span.*

Hyoscyamus. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solaneæ. *Gen. Ch.* *Corolla* funnel-form, obtuse. *Stamens* inclined. *Capsules* covered with a lid, two-celled. *Willd.*

Hyoscyamus niger. Willd. *Sp. Plant.* i. 1010; Woodv. *Med. Bot.* p. 204. t. 76; Bigelow, *Am. Med. Bot.* i. 161. Henbane is a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, bearing considerable resemblance to that of parsley, for which it has been eaten by mistake. The stem is erect, round, branching, from one to three feet in height, and thickly furnished with leaves. These are large, oblong ovate, deeply sinuated, with pointed segments, undulated, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green colour. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downwards. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. Their colour is an obscure yellow, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx, and containing numerous small, irregular, brown or ash-coloured seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank offensive smell.

This species of Hyoscyamus is found in the northern and eastern sections of the United States, occupying waste grounds in the vicinity of the older settlements, particularly graveyards, old gardens, and the foundations of ruined houses. We have seen a specimen brought from the ruins of Ticonderoga. It is rare, however, in this country, of which it is not a native, having been introduced from Europe. In Great Britain, France, Germany, and other parts of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. It flowers in June and July.

The *H. albus*, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, which it resembles exactly in medicinal properties.

All parts of the *Hyoscyamus niger* are possessed of activity. The leaves only are considered officinal in the Pharmacopœias of the United States and Dublin; the leaves and seed have been adopted by the London College; and the whole herb by the College of Edinburgh. Much of the efficacy of henbane, depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. Those of the second year are asserted by Mr. Houlton to be greatly preferable to those of the first. The latter, he informs us, are less clammy and fetid, yield less extractive matter, and are medicinally much less efficient. As the plant is sometimes destroyed by the severe winters in England, no leaves of the second year's growth are obtainable, and the market is on these occasions supplied with the medicine of inferior quality. This is, perhaps, one of the causes of its great inequality of strength, and uncertainty of operation. (See *N. Am. Med. and Surg. Jour.* vol. ii. p. 484.) The root also is said to be much more poisonous in the second year than the first.

Properties. The recent leaves have, when bruised, a strong, disagreeable, narcotic odour, somewhat like that of tobacco. Their taste is mucilaginous, and very slightly acrid. When dried, they have little smell or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odour. Their virtues are completely extracted by diluted alcohol. The watery infusion is of a pale yellow colour, insipid, with the narcotic odour of the plant. The leaves have been analyzed by Lindbergsen, who obtained from them a narcotic principle. The seeds, analyzed by Brandes, yielded 24.2 per cent. of fixed oil, 1.4 of a solid fatty substance, traces of sugar, 1.2 of gum, 2.4 of bassorin, 1.5 of starch, 3.4 of a substance soluble in water, insoluble in alcohol, and precipitated by infusion of galls (phyteumacolla, *Brandes*), 4.5 of albumen soluble or coagulated, 26.0 of vegetable fibre, 24.1 of water, and 9.7 of saline matters, including an alkaline principle called *hyoscyamin* or *hyoscyamia*, combined with malic acid. This principle is obtained, according to Brandes, by precipitating with an alkali the decoction of the seeds, washing the precipitate, and treating it with alcohol. It crystallizes in long prisms, has a very strong taste, and forms crystallizable salts with sulphuric and nitric acids. These salts are said to have the same effect upon the pupil as the henbane itself. It is proper, however, to state that M. Chevallier, a very skilful analytical chemist of Paris, was unable to procure any of this supposed new alkaline principle; and MM. Brault and Poggiale, upon repeating the process of

Brandes, obtained only a powder consisting of salts of potassa, lime, and magnesia.*

Medical Properties and Uses. Hyoscyamus ranks among the narcotics. In moderate quantities it gently accelerates the circulation, increases the general warmth, occasions a sense of heat in the throat, and after a short period induces sleep. This action is sometimes attended with vertigo, pain in the head, and dilated pupils; and the medicine occasionally acts as a diaphoretic or diuretic, or even produces a pustular eruption. It does not constipate like opium, but, on the contrary, often proves laxative. In over doses it powerfully irritates the alimentary canal and brain, giving rise to pain in the bowels, diarrhœa, delirium or stupor, convulsions, great arterial prostration, petechiæ, and other alarming symptoms, which sometimes end in death. Dissection exhibits marks of inflammation of the stomach and bowels. The poisonous effects are best counteracted by emetics, and the subsequent use of acid drinks, such as lemon-juice and vinegar. Numerous instances might be adduced from authors to prove the deleterious influence of all parts of the *H. niger*, when taken in large quantities. Upon inferior animals its effects are not always the same. While it proves fatal to birds and dogs, the leaves are eaten with entire impunity by horses, cows, sheep, goats, and swine. It is not impossible that injury has in some cases resulted from the use of milk derived from cows or goats which had been feeding on henbane.

The remedial operation of hyoscyamus is anodyne and soporific. The medicine was known to the ancients, and was employed by some of the earlier modern practitioners; but had fallen into disuse, and was almost forgotten when Baron Störck again introduced it into notice. By this celebrated physician and some of his successors it was prescribed in numerous diseases, and, if we may credit their testimony, with the happiest effects; but subsequent experience of its operation has been such as very much to narrow the extent of its application. It is at present used almost exclusively to relieve pain, procure sleep, or quiet irregular nervous action; and is not supposed to exercise any specific curative influence over particular diseases. Even for the purposes which it is calculated to answer, it is infinitely inferior to opium or its preparations; and is generally resorted to only in cases in which the latter remedy is from peculiar circumstances deemed inadmissible. Hyoscyamus has one great advantage over opium in certain cases, that it has no tendency to produce constipation. The diseases to which it is applicable it would be useless to enumerate, as there are few complaints in which circumstances might not be such as to call for its employment. Neuralgic and spasmodic affections, rheumatism, gout, hysteria, and various pectoral diseases, as catarrh, pertussis, asthma, phthisis, &c. are among those in which it is most frequently prescribed. In Europe, where the fresh leaves are readily obtained, it is often applied externally in the shape of lotion, cataplasm, or fomentation to allay pain and irritation, in scrofulous or cancerous ulcers, scirrhous, hemorrhoidal, or other painful tumours, gouty and rheumatic swellings, and nervous headach. The smoke of the leaves or seeds has also been used in toothach; but the practice is deemed hazardous. The effect of henbane in dilating the pupil, when applied to the conjunctiva, has already been noticed. For this purpose it is used by European oculists, previously to the operation for cataract. An infusion of the leaves, or a solution of the extract is dropped into the eye. The effect is usually greatest at the end of four hours from the time of application, and in twelve hours ceases entirely. Vision is not impaired during its continuance. Reisinger recommends for this purpose a solution of hyoscyamia in the proportion of one grain to twenty-four of water, of which one drop is to be applied to the eye.

---

* Geiger and Hesse have published a process by which they believe that they have succeeded in extracting an alkaline principle from the seeds of this species of Hyoscyamus. But the question of its existence may yet be considered as unsettled. For an account of the process of Geiger and Hesse, the reader is referred to the Journal of the Philadelphia College of Pharmacy, vol. vi. p. 318.

Henbane may be given in substance, extract, or tincture. The dose of the powdered leaves is from five to ten grains. The extract is exceedingly variable and precarious in its operation, being sometimes active, sometimes almost inert. The usual dose is one or two grains, repeated and gradually increased till the desired effect is obtained. Cullen rarely procured the anodyne operation of the medicine till he had carried the dose to eight, ten, or even fifteen or twenty grains. Collin pushed it to thirty-six grains; and Professor Fouquier, who experimented largely with hyoscyamus in the Hôpital de la Charité gave two hundred and fifty grains of the extract during twenty-four hours, without any specific or curative impression. (Richard, *Elem. Hist. Nat. Med.*) The extract here alluded to is the inspissated juice, prepared as directed by the Pharmacopœias. (See *Extractum Hyoscyami.*)

It is said by the French writers that the alcoholic extract, as prepared by M. Planche, is more certain and effectual. He directs one part of the plant to be macerated with four parts of alcohol for four days; three-fourths of the alcohol is then to be distilled, and the remaining fourth evaporated by a salt-water bath till the residue assumes the consistence of an extract. The preparation thus made has a fine green colour, and preserves the odour of the plant. The dose to begin with is one or two grains, which may be increased gradually to twenty or even thirty grains.

The dose of the tincture is one or two fluidrachms. A good plan in administering any of the preparations of hyoscyamus is to repeat the dose every hour or two till its influence is felt.

HYSSOPI OFFICINALIS HERBA. *Ed.*

Common Hyssop.

Hyssope, *Fr.*; Gemeiner Isop, *Germ.*; Issopo, *Ital.*; Hisopo, *Span.*

HYSSOPUS. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Corolla* lower lip three-parted, with a small intermediate subcrenate segment. *Stamens* straight, distant. *Willd.*

Hyssopus officinalis. Willd. *Sp. Plant.* iii. 47; Woodv. *Med. Bot.* p. 318. t. 113. This is a perennial plant, with numerous erect, quadrangular, somewhat branching stems, which are woody in their inferior portion, about two feet high, and furnished with opposite, sessile, lanceolate linear, pointed, punctate leaves. The flowers are violet coloured or blue, sometimes white, turned chiefly to one side, and arranged in half verticillated, terminal, leafy spikes. The upper lip of the corolla is roundish and notched at the apex, the lower is divided into three segments, of which the undermost is obovate.

Common hyssop is a native of the continent of Europe, where, as well as in this country, it is also cultivated in gardens. The flowering summits and leaves are the officinal parts.

They have an agreeable aromatic odour, and a warm, pungent, bitterish taste. These properties they owe to an essential oil, which may be obtained separate by distillation with water, and rises also with alcohol.

Medical Properties, &c. Hyssop is a warm gently stimulant aromatic, applicable to the same cases with the other labiate plants. Its infusion has been much employed in chronic catarrhs, especially in old people, and those of debilitated habit of body. It acts by facilitating the expectoration of the mucus which is too abundantly secreted. In this country, however, it is very seldom used by regular practitioners. W.

* * *

ICHTHYOCOLLA. *U.S.*

Isinglass.

"Acipenser huso, et Acipenser Ruthenus. Vesica natatoria. *The swimming bladder.*" *U.S.*

Fish-glue; Ichthyocolle, colle de poisson, *Fr.;* Hausenblase, Fischleim, *Germ.;* Colla di pesce, *Ital.;* Cola de pescado, *Span.*

Isinglass is a gelatinous substance, prepared chiefly from the sounds or swimming bladders of fishes, especially those of different species of sturgeon. Though no longer retained by any of the British Colleges in their officinal catalogues, it still has a place in the Pharmacopœia of the United States, and being universally kept in the shops, requires at least a brief notice in the present work.

In most fishes there is a membranous bag, placed in the anterior part of the abdomen, communicating frequently, though not always, by means of a duct, with the œsophagus or stomach, and containing usually a mixture of oxygen and nitrogen gases in various proportions. From the supposition that it was intended by its expansion or contraction to enable the fish to rise or sink in the water, it has been denominated *swimming bladder.* It is of different shape in different fishes, and consists of three coats, of which the two interior are thin and delicate, the outer tough and of a silvery whiteness.

The *Acipenser Huso* or *beluga* of the Russians, and the *A. Ruthenus* or sterlet, are designated by the Pharmacopœia as the species of sturgeon from which isinglass is procured; but two others, the *A. Sturio* or common sturgeon, and *A. stellatus*, or starred sturgeon, also furnish large quantities to commerce. All these fish inhabit the interior waters of Russia, especially the Wolga, and other streams which empty into the Caspian Sea. Immense quantities are annually taken and consumed as food by the Russians. The air-bags are removed from the fish, and having been slit open and washed in water in order to separate the blood, fat, and adhering extraneous membranes, are spread out, and when sufficiently stiffened, are formed into cylindrical rolls, the ends of which are brought together and secured by pegs. The shape given to the roll is that of a staple, or more accurately that of a lyre, which it firmly retains when dried. Thus prepared it is known in commerce by the name of *staple isinglass*, and is distinguished into the *long* and *short staple.* Sometimes the membranes are dried in a flat state, or simply folded, and then receive the name of *leaf* or *book isinglass.* The scraps or fragments of these varieties, with various other parts of the fish, are boiled in water, which dissolves the gelatin, and upon evaporation leaves it in a solid state. This is called *cake isinglass*, from the shape which it is made to assume. It is sometimes, however, in globular masses. Of these varieties the *long staple* is said to be the best; but the finest *book isinglass* is not surpassed by any brought to this country. That in *cakes* is brownish, of an unpleasant odour, and employed only in the arts. Inferior kinds, with the same commercial titles, are said to be prepared from the peritoneum and intestines of the fish.

Isinglass little inferior to the Russian is made in Iceland, from the sounds of the cod and ling.

We receive from Brazil the air-bladders of a large fish, prepared by drying them in their distended state. They are oblong, tapering and pointed at one end, bifid with the remains of their pneumatic duct at the other, and of a firm consistence.

Isinglass of good quality is now obtained in New York from the weak fish—*Labrus Squeteague* of Mitchell—and perhaps others caught in the neighbourhood. The sounds are dried whole, or merely slit open, and vary much in size and texture, weighing from a drachm up to an ounce.

Another kind, of inferior quality, is prepared in New England, from the intestines of the *Gadus Morrhua* or cod-fish. It is in the form of thin ribbands, several feet in length, and from an inch and a half to two inches in width. It has been used to a considerable extent in this country; but is less soluble than the Russian, and affords a dark coloured solution.*

Isinglass is sometimes kept in the shops cut into fine shreds, and is thus more easily acted on by boiling water.

In its purest form it is whitish, semi-transparent, of a shining, pearly appearance, and destitute of smell and taste. The inferior kinds are yellowish and more opaque. In cold water it softens, swells up, and becomes opalescent. Boiling water entirely dissolves it, with the exception of a minute proportion of earthy impurities, amounting, according to Mr. Hatchet, to less than two parts in the hundred. The solution on cooling assumes the form of a jelly, which consists of pure gelatin and water. Isinglass is in fact the purest form of *gelatin* with which we are acquainted, and may be used whenever this principle is required as a test. It is insoluble in alcohol, but is dissolved readily by most of the diluted acids, and by the liquid alkalies. It has a strong affinity for tannin, with which it forms an insoluble compound. Boiled with concentrated sulphuric acid, it is converted into a peculiar saccharine matter. Its aqueous solution speedily putrefies.

Medical Properties and Uses. Isinglass has no peculiar medical properties. It may be given internally, in the form of jelly, as a highly nutritious article of diet; but it has no advantages over the jelly prepared from calves-feet. Three drachms impart sufficient consistence to a pint of water. It is employed in the arts for clarifying liquors, and imparting lustre to various woven fabrics. Added in small quantity to vegetable jellies, it gives them a tremulous appearance, which they want when unmixed. As a test of tannin it is used in solution, in the proportion of a drachm to ten fluidounces of distilled water. It forms the basis of the English court-plaster.

W.

Inula Helenium. Willd. *Sp. Plant.* iii. 2089; Woodv. *Med. Bot.* p. 64. t. 26. Elecampane has a perennial root, and an annual stem which is round, furrowed, villous, leafy, from three to six feet high, and branched near the top. The leaves are large, ovate, serrate, crowded with reticular veins, smooth and deep green upon the upper surface, downy on the under, and furnished with a fleshy midrib. Those which spring directly from the root are petiolate, those of the stem sessile and embracing. The flowers are large, of a golden yellow colour, and stand singly at the ends of the stem and branches. The calyx exhibits several rows of imbricated ovate scales. The florets of the ray are numerous, spreading, linear, and tridentate at the apex. The seeds are striated, quadrangular, and furnished with a simple, somewhat chaffy pappus.

This large and handsome plant is a native of Europe, where it is also cultivated for medical use. It has been introduced into our gardens, and has become naturalized in some parts of the country, growing in low meadows, and on the road sides, from New England to Pennsylvania. It flowers in July and August. The roots, which are the officinal part, should be dug up in autumn, and in the second year of their growth. When older they are apt to be stringy and woody.

The fresh root of elecampane is very thick and branched, having whitish cylindrical ramifications which are furnished with thread-like fibres. It is externally brown, internally whitish and fleshy; and the transverse sections present radiating lines. The dried root, as found in the shops, is usually in longitudinal or transverse slices, and of a grayish colour internally. The smell is slightly camphorous, and, especially in the dried root, agreeably aromatic. The taste, at first glutinous and said to resemble that of rancid soap, becomes, upon chewing, warm, aromatic, and bitter. Its medical virtues are extracted by alcohol and water, the former becoming most strongly impregnated with its bitterness and pungency. A peculiar principle resembling starch was discovered in elecampane by Rose, a chemist of Berlin, who named it *alantin;* but the title *inulin*, proposed by Dr. Thomson has been generally adopted. It differs from starch in being precipitated unchanged from its solution in boiling water when the liquor cools, and in not affording a blue colour with iodine. It has been found in the roots of several other plants. Besides this principle, elecampane contains, according to John, a white, concrete substance, called *helenin*, intermediate in its properties between the essential oils and camphor, and separable by distillation with water; a bitter extractive, soluble in water and alcohol; a soft, acrid, bitter resin, having an aromatic odour when heated; gum; albumen; lignin; traces of volatile oil; a little wax; and various saline substances.

Medical Properties and Uses. Elecampane is tonic and gently stimulant, and has been supposed to possess diaphoretic, diuretic, expectorant, and emmenagogue properties. By the ancients it was much employed, especially in the complaints peculiar to females; and it is still occasionally resorted to in cases of retained or suppressed menstruation. In this country it is chiefly used in chronic diseases of the lungs, and is sometimes beneficial when the affection of the chest is attended with weakness of the digestive organs, or with general debility. From a belief in its deobstruent and diuretic virtues, it was formerly prescribed in chronic engorgements of the abdominal viscera, and the dropsy to which they so often give rise. It has also been highly recommended both as an internal and external remedy in tetter, psora, and other diseases of the skin. The usual modes of administration are in powder and decoction. The dose of the former is from a scruple to a drachm. The decoction may be prepared by boiling half an ounce of the root in a pint of water, and given in the dose of one or two fluidounces.

IODINUM. *U.S.*

Iodine.

Off. Syn. IODINIUM. *Dub.*

Iode, *Fr.;* Iod, *Germ.;* Iodina, *Ital.*, *Span.*

Iodine was discovered in 1812 by Courtois, a soda manufacturer of Paris. Its nature was immediately investigated by Sir H. Davy and Gay-Lussac; but particularly by the latter, who presented to the scientific world a very complete chemical history of it, pointed out its analogy to chlorine, and showed the great probability of its simple nature. Its powers as a therapeutic agent were shortly afterwards tried; and these being found valuable, it came into use with many practitioners. In 1826 it was introduced very properly into the officinal catalogue of the revised edition of the Dublin Pharmacopœia, and in 1830 into that of the United States. As yet it has not been recognised by the London or Edinburgh College.

Natural State and Preparation. Iodine exists naturally in certain marine vegetables, particularly the fuci or common sea-weeds; in the animal kingdom, in sponge, the oyster, various polypi, and other sea animals; and in the mineral kingdom, in sea water in minute quantity, in certain salt springs, and united with silver in a rare Mexican mineral. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by Dr. William Usher; and afterwards in the same water by Dr. J. H. Steel, who ascertained it to be in the state of hydriodate of soda. (See *Aqua*, p. 99.) It has also been detected in small quantity in the Kenhawa saline waters, by Professor Emmet of the University of Virginia. When in solution, it always occurs in union with hydrogen and a base as a hydriodate. In sea-weeds, according to Gaultier de Claubry, it exists in the state of hydriodate of potassa; and it is from the ashes of these that iodine is most readily obtained. Berzelius conceives the iodine to exist in these ashes as a hydriodate of soda. In both England and France, sea-weeds are burnt for the sake of the carbonate of soda contained in their ashes. In England the incinerated product is called *kelp*, in France, *vareck;* and it contains, besides carbonate of soda, the iodine which pre-existed in the weeds. The manner in which kelp is treated, in order to obtain the iodine, is to act upon it with cold water, and to concentrate the solution obtained till a pellicle is formed, when it is allowed to crystallize. By this treatment, nearly all the carbonate of soda and chloride of sodium, (common salt,) are separated, and the uncrystallizable residue consists almost exclusively of a solution of hydriodate of potassa. This is then mixed in a retort with an excess of strong sulphuric acid, and, when the effervescence has ceased, with a portion of peroxide of manganese in fine powder. A receiver is now adapted to the retort, and heat applied. The sulphuric acid unites with the potassa, and disengages the hydriodic acid, which is instantly decomposed; its hydrogen uniting with the oxygen of the peroxide, and the liberated iodine being driven over by the heat, and condensed in the receiver. The process may be conducted without the manganese, in which case, the hydriodic acid is deprived of its hydrogen by part of the sulphuric acid, which in consequence becomes converted into sulphurous acid; but the process conducted in this manner is less eligible than the other, as the hydriodic acid is less completely decomposed. The iodine as thus obtained is contaminated with some acid, and may be purified by washing it, and afterwards redistilling it from a weak solution of potassa. It may then be dried by pressing it between folds of bibulous paper, and must be kept in glass stoppered bottles, as corks are quickly corroded.

Properties. Iodine is a soft, friable, opaque, elementary solid, in the form of crystalline scales of a blueish-black colour and metallic lustre. It possesses a strong and peculiar odour, analogous to that of chlorine, and an acrid taste. Applied to the skin, it produces an evanescent yellow stain. Its sp. gr. is a little less than 5; its fusing point, 225°; and boiling point, 347°. It is a volatile substance, and evaporates even at common temperatures, provided it be in a moist state. As it occurs in commerce, it generally contains twelve per cent. of water. Its vapour has a rich purple colour, a property which suggested its name, and a sp. gr. of 8.7, being the heaviest aëriform substance known. When it comes in contact with cool surfaces, it condenses in brilliant steel-gray crystals. Iodine is soluble in 7000 times its weight of water, and in a much smaller quantity of alcohol or ether. Its solution in the former has no taste, a feeble odour, and a light brown colour; in the latter, it possesses a deep brown hue. Its solubility in water is very much increased by the addition of certain salts, as the chloride of sodium, nitrate of ammonia, or iodide of potassium. In chemical habitudes, it resembles chlorine; but its affinities are much weaker. Its equivalent number is 126.3. It combines with most of the non-metallic, and nearly all the metallic, bodies, forming, when the combination is not acid, the class of compounds called *iodides*. Some of these, as the iodides of potassium, mercury, and lead, are used in medicine. (See *Potassii Iodidum.*) It forms with oxygen, one oxide, and three acids, the *iodous*, *iodic* and *periodic acid*, and with hydrogen, a gaseous acid, analogous in properties and constitution to the muriatic, called *hydriodic acid.*

Iodine may, in most cases, be recognised by the appearance of its characteristic purple vapour; but where this cannot be made evident, it is detected unerringly by starch, which produces with it an insoluble combination of a deep blue colour. This test was discovered by Colin and Gaultier de Claubry, and, according to Stromeyer, is so delicate, that it will indicate the presence of iodine contained in 450,000 times its weight of water. In order that the test may succeed, the iodine must be in a free state, and the solutions cold. To render it free where it happens to be in saline combination, a little nitric acid must be added to the solution suspected to contain it.

Iodine has been occasionally adulterated with animal charcoal and peroxide of manganese. The presence of these substances is easily discovered by exposing the suspected iodine to heat, when they will remain behind. Of latter years, however, iodine has fallen so much in price, that the motive for these frauds is very much lessened.

Medical Properties and Uses. Iodine was first employed as a medicine, for the cure of goitre, by Dr. Coindet of Geneva. It operates as a general excitant of the living actions, but particularly of the absorbent and glandular systems; and is capable of producing very important alterative effects. It appears to act by entering into the circulation. Its most constant effect is to excite the digestive organs, as shown by its increasing the appetite; and in some instances it proves powerfully diuretic. Salivation is occasionally induced by it, and this effect is more apt to occur in males than in females. Notwithstanding, it has been recommended as a remedy in cases of severe salivation, given in doses of two grains daily increased to four, in a vehicle composed of cinnamon water and simple syrup. (*Am. Journ. of Med. Sci., from Hufeland*, xiii. 533.) When taken in an overdose it acts as an irritant poison. In doses of two drachms administered to dogs, it produced irritation of the stomach, and death in seven days; and the stomach on dissection was found studded with numerous little ulcers of a yellow colour. In a dose of from four to six grains in man, it produces a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. These facts demonstrate the activity of iodine, and show the necessity of caution in its exhibition. When given in incautious doses, or too long continued, it sometimes produces unpleasant and even dangerous symptoms; such as restlessness, palpitation, a sense of burning along the gullet, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, rapid and extreme emaciation, and frequent pulse. But these results can only take place from great and culpable negligence on the part of the practitioner; for upon the appearance of the first symptoms of fever or general nervous disturbance, the remedy ought instantly to be laid aside. Dr. Lugol of Paris, who has used iodine more extensively and methodically than any other practitioner, has never observed any alarming effects to arise from its exhibition in the small doses in which he is in the habit of giving it. He has not found it to cause emaciation, hæmoptysis, pulmonary tubercles, or the other bad effects so frequently attributed to it. On the contrary, in the hospital of Saint Louis, the theatre of his extensive experience, many of the patients gained flesh and improved in health.

Iodine has been principally employed in diseases of the absorbent and glandular systems. In ascites it has been used with success by Dr. Baron, an English practitioner. It is said not to act efficaciously while the abdomen is tense, and the absorbents consequently compressed; but operates only after this state of things is removed by tapping. It has also been recommended in ovarian dropsy. In glandular enlargements its use has proved more efficacious than perhaps in any other class of diseases. Dr. Coindet discovered its extraordinary power in promoting the absorption of the thyroid gland, in the disease called bronchocele; and it has also been used with more or less success in enlargements of the liver, spleen, mammæ, testes, and uterus. Its emmenagogue power has been noticed by several practitioners; and Dr. Lugol mentions several instances, among his scrofulous patients, in which it cured obstructed and painful menstruation. It has been recommended in leucorrhœa (*N. Am. Arch.* I. 218), and has been found useful in gonorrhœa and gleet. In certain diseases of the nervous system also, iodine has proved useful in the hands of some practitioners. Dr. Manson, of Nottingham, England, in his work, published in 1825, on the medical effects of iodine, has recorded cases of its efficacy in chorea, paralysis, and deafness. It is, however, in scrofulous diseases that the most interesting trials have been made with this remedy; and there is not wanting authentic testimony of its efficacy in these affections. Dr. Coindet and Sir Andrew Halliday have both prescribed it with benefit; and Dr. Manson reports a number of cases of scrofulous disease, in the form of enlarged glands, ulcers, and ophthalmia, occurring in his practice between 1821 and 1824, in a large proportion of which the disease was either cured or meliorated, and the general health very much improved. We are indebted, however, to Dr. Lugol for the most extended and valuable researches on the use of iodine in the different forms of scrofula. This physician began his trials with the remedy in the hospital Saint Louis in 1827, and made known his results in three Memoirs published in 1829–30 and 31. These memoirs give the details of a success which would stagger belief, were the cases not substantiated by two committees of distinguished physicians of the French Royal Academy of Sciences. The scrofulous affections in which Dr. Lugol succeeded by the administration of iodine were glandular tubercles, especially of the neck, ophthalmia, ozæna, noli me tangere (dartre rongeante scrophuleuse), and fistulous and carious ulcers. He also obtained favourable results in some cases of scrofulous syphilis by the use of the iodide of mercury. In connexion with Dr. Lugol's results in scrofulous affections, it may be proper to mention that Dr. Manson derived benefit from the use of iodine in white swelling, hip-joint disease, and distortions of the spine, diseases generally admitted to be more or less dependent on a scrofulous taint.

Iodine is employed both internally and externally. Internally it is generally used in the form of tincture, and externally in combination, in the form of iodide of potassium, or of iodide of mercury or lead. Dr. Lugol objects to the tincture as of unequal strength, and as being liable to have the iodine precipitated by water on the surface of the stomach, where it is apt to produce too irritating an action. This physician prefers a mixed solution of iodine and iodide of potassium in distilled water; the iodide being employed merely for the purpose of dissolving the iodine more completely. He employs three strengths, namely three-fourths of a grain, one grain, and a grain and a quarter of iodine to half a pint of distilled water; the quantity of iodide of potassium being in each solution double the quantity of the iodine.* These solutions are permanent, perfectly transparent, and of an orange colour. The mode of administration employed by Dr. Lugol is to give at first two-thirds of the weakest solution, or half a grain of iodine daily for the first fortnight; the weakest solution entire for another fortnight; the medium solution during the fourth and fifth fortnight; and lastly, in some cases, the strongest solution for the remainder of the treatment. In the majority of cases, however, he had not occasion to resort to the strongest solution. He gives half the daily quantity in the morning fasting, and the other half, an hour before dinner; each portion being slightly sweetened at the moment of taking it. For the convenience of making the weak iodine solution, or of administering the remedy by drops, Dr. Lugol prepares a concentrated solution, consisting of a scruple of iodine, and two scruples of iodide of potassium dissolved in seven fluidrachms of water.† Of this solution the dose is six drops twice a day (in the morning fasting, and an hour before dinner) in a glass of sweetened water, gradually increased weekly by two drops at a time, until the dose reaches to thirty or thirty-six drops. For children under seven years, the dose is two drops twice a day, gradually increased to five. It will be observed that these doses are considerably less than those usually employed on the recommendation of Dr. Coindet.

---

* In the original, the grains are French, and the quantity of water eight French ounces; but to facilitate prescription we have supposed them English grains, and have substituted half a pint for the eight French ounces of water; changes which will not make the solutions materially stronger.

† In the original it is *seven ounces;* but from the context of the author, this is evidently a misprint for *seven drachms.*

The external treatment by iodine may be divided into local and general. By its use in this way it does not create a mere topical effect on the skin; but by its absorption produces its peculiar constitutional impression. Dr. Lugol has given a number of formulæ for preparations for the local use of iodine, a short account of which will be presented in this place. His *iodine ointment* varies in strength from six to twelve grains of iodine, mixed with from two to four scruples of iodide of potassium, to the ounce of lard. It has a mahogany colour. He employs it in frictions to scrofulous tumours, and as a dressing to scrofulous ulcers. The *ointment of protiodide of mercury* which he recommends, consists of from one to two scruples of the mercurial iodide to the ounce of lard. Its proper colour is canary yellow; but occasionally it has a decided greenish tint, derived from the presence of protoxide of mercury, or an orange colour, when it contains the biniodide. This ointment, which has the advantage of producing very little pain, is used by Dr. Lugol in noli me tangere, and in all scrofulous ulcers which have a syphilitic aspect. Dr. Lugol's *iodine lotion* consists of from two to four grains of iodine to a pint of distilled water, the solution being rendered complete by the addition of double the quantity of iodide of potassium. This is used by injection principally in scrofulous ophthalmia, ozæna, and fistulous ulcers. A *rubefacient solution* may be formed by dissolving half an ounce of iodine and an ounce of iodide of potassium in six fluidounces of distilled water. This is useful for exciting scrofulous ulcers, for touching the eye-lids, and as an application to recent scrofulous cicatrices, to render them smooth and less prominent. A certain quantity of the rubefacient solution added to warm water, makes a convenient local bath for the arms, legs, feet, or hands; and mixed with linseed meal, or some similar substance, it forms a cataplasm, useful in particular cases, especially where the object is to promote the falling off of scabs. The only remaining local application to be mentioned, is what Dr. Lugol calls *iodine caustic.* It consists of iodine and iodide of potassium, each an ounce, dissolved in two ounces of distilled water, and is used to stimulate or destroy soft and fungous granulations. Its employment in this way has been attended with particularly good effect in noli me tangere.

The external application of iodine when general, consists in the use of iodine baths, a mode of applying the remedy which originated with Dr. Lugol. This mode of administration is considered very valuable by this physician, on account of the great extent of the skin, which furnishes the means of introducing a considerable quantity of iodine into the circulation, without deranging the digestive functions, an object of great importance, where the medicine produces peculiar irritation of the stomach. The iodine bath for adults, according to the formula of Dr. Lugol, should contain from two to four drachms of iodine, with double that quantity of iodide of potassium, dissolved in water, in a *wooden* bath tub, the proportion of the water being about a gallon for every three grains of iodine employed. The quantity of ingredients for the baths of children is one-third as much as for adults, but dissolved in about the same proportional quantity of water. The quantity of iodine and iodide for a bath being determined on, it is best to dissolve them in a small quantity of water, (half a pint for example,) before they are added to the water of the bath; as this mode of proceeding facilitates their thorough diffusion. In the composition of these baths, the iodide of potassium is used by Dr. Lugol, merely to promote the solubility of the iodine, and not as a medicinal agent; as upon trial, a bath containing it alone proved nearly inert.

The iodine baths, which may be directed three or four times a week, usually produce a slight rubefacient effect, but occasionally, a stronger impression, causing the epidermis to peel off, particularly of the arms and legs. The skin at the same time contracts a deep yellow tinge, which usually disappears in the interval between the baths.

Since the publication of Dr. Lugol's memoirs, detailing his success with iodine in the treatment of scrofulous affections, even of the most unpromising aspect, his practice has been imitated and extended by several practitioners, and generally with encouraging results. Dr. Bermond, of Bordeaux, has succeeded with the iodine treatment in enlarged testicle from a venereal cause, scrofulous ophthalmia of six years' duration, and scrofulous ulcers and abscesses of the cervical and submaxillary glands. In numerous other cases of scrofula under his care, the iodine treatment proved beneficial, though before its commencement, the cases underwent no improvement. The only peculiarity in Dr. Bermond's treatment, was that, in some cases, he associated opiate preparations with the iodine. In the case of ophthalmia which he treated, the collyrium employed consisted of tincture of iodine thirty drops, laudanum thirty-six drops, to four fluidounces of distilled water. When the local application of the iodine created much pain or rubefaction, he advantageously combined extract of opium with it. A plaster which he found efficacious as an application to the enlarged parotid, in one of his cases, consisted of lead plaster (diachylon) and iodide of potassium, (hydriodate of potassa,) each, four parts; iodine and extract of opium, each, three parts. In confirmation of Dr. Bermond's views, M. Lemasson, one of the house pupils of the hospital St. Louis, has published a number of cases proving the efficacy of a combination of iodine and opium, in the local treatment of scrofulous ulcerations. He concludes from his experience that the union of opiate preparations with iodine imparts to the latter, in many cases, new and valuable powers. One of the combinations which he employed consisted of iodine *fifteen grains*, iodide of potassium *a drachm*, Rousseau's laudanum, *two drachms*, mixed up into an ointment with fresh lard *two ounces*.

Besides the *protiodide* of mercury, already mentioned as used by Dr. Lugol in scrofulous syphilis, the *biniodide* of this metal has been resorted to in similar cases with apparent advantage. The latter preparation must be used with caution, on account of its comparative strength; as it contains a double proportion of iodine, and bears the same chemical relation to the protiodide as corrosive sublimate does to calomel. The average dose of the protiodide is two grains daily, carried usually to the extent of salivation; of the biniodide, from the eighth to the sixth of a grain, three times a day. The ointment of the biniodide of mercury may be made of about the same strength as that of protiodide, already mentioned.

The last preparation of iodine to be noticed in this place is the *protiodide of lead.* This compound was introduced as a remedy for scrofulous swellings and ulcerations by two Parisian physicians, MM. Cottereau and De Lisle, and has been employed at the Hôpital des Enfans, and at La Pitié by Guersent and Velpeau with striking success. The remedy was used internally, and at the same time by frictions on the tumors. The dose is from a quarter to half a grain, repeated several times a day. The ointment is formed by rubbing up a drachm of the iodide with an ounce of lard.

As the iodine compounds last mentioned are not officinal, it may be useful to give an outline of the mode in which they are prepared. The *protiodide of mercury* is formed by precipitation, by adding a solution of hydriodate of potassa (iodide of potassium dissolved in water) to a solution of the *proto*nitrate of mercury; and the *biniodide*, in a similar manner, by the addition of the hydriodate to a solution of corrosive sublimate. Both cases are instances of double decomposition; and the difference in the precipitate depends entirely on the state of oxidation of the metal in the mercurial salt employed. The protiodide is canary yellow, the biniodide, of a beautiful carmine red tint. In preparing the latter, it is necessary to add the hydriodate drop by drop, as the precipitate is soluble in an excess of either of the salts employed in its formation. The *protiodide of lead* is formed by adding a solution of iodide of potassium to a solution of nitrate of lead. Protiodide of lead precipitates, and nitrate of potassa remains in solution. This iodide is of a fine yellow colour, soluble in 1235 parts of cold, and in 194 parts of boiling water, from which latter upon cooling it crystallizes in brilliant yellow hexagonal plates. It is capable of uniting in three proportions with the protoxide of lead, forming pulverulent *insoluble* oxy-iodides which must not be confounded with the pure iodide, which alone has been used for medicinal purposes. Its freedom from the oxy-iodides is readily ascertained by the action of boiling water, which takes up the whole of it when pure, and deposites it again, on cooling, in crystals, having the characteristic appearance above mentioned. The oxy-iodides, if present, will be left as an insoluble residue. (See the paper of M. Denot on the iodides of lead, *Journ. de Pharm.* xx. 1.)

The results obtained by Dr. Lugol and others in the treatment of scrofulous diseases by the iodine preparations are now so diversified, as to leave no doubt of their superiority over all the remedies heretofore used in the same class of affections. A considerable number of practitioners in the United States have employed them in the same diseases with encouraging success; but at the same time, there have been, as was to be expected in the treatment of so obstinate a disease, a number of failures. To judge fairly, however, of Dr. Lugol's remarkable results, it is not sufficient for our practitioners to use iodine; but they should use it in the peculiar manner, and with the observance of all the rules, which are so fully laid down in the published memoirs of this physician. Reasoning on the subject, we can readily conceive that a dilute aqueous solution of iodine may act differently from the tincture; and that a therapeutical agent may be introduced gradually and imperceptibly into the current of the circulation in one form of administration, and thus be capable of producing important alterative effects; while in another, it may create irritation and even ulceration of the stomach, and fail to be absorbed. A case in point is furnished by mineral waters, which, though generally containing a minute portion of saline matter, often produce remedial effects which cannot be obtained by their constituents given in larger doses.*

IPECACUANHA. *U.S.*

Ipecacuanha.

"Cephaëlis ipecacuanha. *Richard.* Callicocca ipecacuanha. *Brotero.* Radix. *The root.*" *U.S.*

Off. Syn. IPECACUANHÆ RADIX. Callicocca Ipecacuanha. Radix. *Lond.;* IPECACUANHÆ RADIX. *Ed.;* CEPHAELIS IPECACUANHA. Radix. *Dub.*

Ipecacuanha, *Fr.;* Brechwurzel, Ipecacuanha, *Germ.;* Ipecacuana, *Ital., Span.*

The term *ipecacuanha*, derived from the language of the South American Indians, has been applied to various emetic roots of American origin. The British Colleges and our national Pharmacopœia recognise only that of the *Cephaëlis Ipecacuanha;* and no other is known by the name in the shops of this country. Our chief attention will, therefore, be confined to this root, and the plant which yields it; but as others are employed in South America, are occasionally exported, and may possibly reach our markets mingled with the genuine drug, we shall, after treating of the true ipecacuanha; give a succinct account of the different varieties, as described by the authors who have most recently written on the subject.

The botanical character of the plant which yields genuine ipecacuanha was long unknown. Pison and Marcgrav, who were the first to notice this medicine, in their work on the natural history of Brazil, published at Amsterdam, A.D. 1648, describe in general terms two plants, one producing a whitish root, distinguished by the name of white ipecacuanha, the other a brown root which answers in their description precisely to the officinal drug. But their account was not sufficiently definite to allow botanists to decide upon the character of the plants; and much uncertainty existed on the subject. The medicine was generally thought to be derived from a species of *Viola*, which Linnæus designated by the title of *V. Ipecacuanha.* Opinion afterwards turned in favour of a plant sent to Linnæus by the celebrated Mutis from New Granada, as affording the ipecacuanha of that country and of Peru. This was described in the *Supplementum* of the younger Linnæus, A.D. 1781, under the name of *Psychotria emetica*, and was long erroneously considered as the source of the true ipecacuanha. Dr. Gomez of Lisbon was the first who accurately described and figured the genuine plant, which he had seen in Brazil, and specimens of which he took with him to Portugal; but Brotero professor of botany at Coimbra, with whom he had left specimens, having drawn up a description, and had it inserted with a figure in the Linnean Transactions, without acknowledgment, has generally enjoyed the credit due to his fellow countryman.* In the paper of Brotero the plant is named *Callicocca Ipecacuanha;* but the term *Callicocca* having been applied by Schreber, without sufficient reason, to a genus previously established and named, has been universally abandoned by botanists for the *Cephaëlis* of Swartz, though this also, it appears, is a usurpation upon the previous rights of Aublet.

* The memoir of Gomez appeared in Lisbon A.D. 1801; the paper of Brotero was published in the sixth volume of the Linnean Transactions of London, which did not appear till the year 1802.

Cephaëlis Ipecacuanha. Richard, *Hist. Ipecac.* p. 21. t. i.; Martius, *Spec. Mat. Med. Brazil.* p. 4. t. i.—*Callicocca Ipecacuanha.* Brotero, *Linn. Trans.* vi. 137. This is a small shrubby plant, with a root from four to six inches long, about as thick as a goose-quill, marked with annular rugæ, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long; but being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-coloured, and knotted, with radicles frequently proceeding from the knots; near the summit pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the base of each pair of leaves are deciduous stipules, embracing the stem, membranous at their base, and separated above into numerous bristle-like divisions. The flowers are very small, white, and collected to the number of eight, twelve, or more, each accompanied with a green bracte, into a semi-globular head, supported upon a round, solitary, axillary footstalk, and embraced by a monophyllous involucre deeply divided into four, sometimes five or six obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.

The plant is a native of Brazil, flourishing in moist, thick, and shady woods, and abounding most within the limits of the eighth and twentieth degrees of south latitude. It flowers in January and February, and ripens its fruit in May. The root is usually collected during the period of flowering, though equally good at other seasons. By this practice the plant is speedily extirpated in places where it is most eagerly sought. Were the seeds allowed to ripen, it would propagate itself rapidly, and thus maintain a constant supply. The root is collected chiefly by the Indians, who prepare it by separating it from the stem, cleaning it, and hanging it up in bundles to dry in the sun. The Brazilian merchants carry on a very brisk trade in this drug. The chief places of export are Rio Janeiro, Bahia, and Pernambuco. It is brought to the United States in large bags or bales.

Genuine ipecacuanha is in pieces two or three lines in thickness, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-coloured, ligneous chord, with a thick cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugæ, separated by very narrow fissures frequently extending nearly down to the central fibre. This appearance of the surface has given rise to the term *annelé* or *annular*, by which the true ipecacuanha is designated in the French works on pharmacy. The cortical part is hard, horny, and semi-transparent, breaks with a resinous fracture, and easily separates from the tougher ligneous fibre, which possesses the medicinal virtues of the root in a much inferior degree. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Much stress has been laid in works on the materia medica upon the colour of the external surface of the ipecacuanha root, and diversity in this respect has even led to the formation of distinct varieties. Thus the epidermis is sometimes deep brown or even blackish, sometimes reddish-brown or reddish-gray, and sometimes light gray or ash-coloured. Hence the distinction into *brown*, *red*, and *gray ipecacuanha.* But these are all derived from the same plant, are essentially the same in properties and composition, and probably differ only in consequence of difference in age, or place of growth, or mode of desiccation. The colours in fact are often so intermingled, that it would be impossible to decide in which variety a particular specimen should be placed. The *brown* is the most abundant in the packages which reach our market. The *red*, besides the colour of its epidermis, presents a rosy tint when broken, and is said to be somewhat more bitter than the preceding variety. The *gray* is much lighter coloured externally, usually rather larger, with less prominent rings and wider fissures, and is still more decidedly bitter. When the bark in either variety is opaque, with a dull amylaceous aspect, the root is less active as a medicine. As the woody part is nearly inert, and much more difficult of pulverization than the cortical, it often happens that when a particular parcel of the root is powdered, the portion which remains last in the mortar possesses scarcely any emetic power; and care should be taken to provide against any defect from this cause. The colour of the powder is a light grayish fawn.

Ipecacuanha has little smell in the aggregate state, but when powdered has a peculiar nauseous odour, which in some persons excites violent sneezing, in others dyspnœa resembling an attack of asthma. The taste is bitter, acrid, and very nauseous. Water and alcohol extract its virtues, which are injured by decoction. Its emetic property resides in a peculiar alkaline principle called *emetin*, or more properly *emetia*, discovered by Pelletier in the year 1817. The cortical portion of the brown ipecacuanha, analyzed by this chemist under the erroneous name of *Psychotria emetica*, yielded in the hundred parts, 16 of an impure salt of emetia, which was at first considered the pure emetic principle, 2 of an odorous fatty matter, 6 of wax, 10 of gum, 42 of starch, 20 of lignin, with 4 parts loss. The woody fibre was found to contain only 1.15 per cent. of the impure emetia. M. A. Richard obtained from the cortical part, the same proportion of emetia as found by Pelletier, but detected some principles not noticed by that chemist, among which were traces of gallic acid. The bark of the red ipecacuanha was found by Pelletier to contain but fourteen per cent. of the impure emetia. The *gray* variety has not been analyzed. One hundred parts of good ipecacuanha contain about 80 of cortical and 20 of ligneous matter.

Emetia when perfectly pure is whitish, inodorous, slightly bitter, pulverulent, unalterable in the air, very fusible, sparingly soluble in cold water and ether, very soluble in alcohol, is not reddened by nitric acid, forms crystallizable salts with the mineral acids and acetic acid, is precipitated by gallic acid from its solutions, and contains nitrogen among its ingredients. It is, however, very difficult to procure it in this state of purity, and the proportion afforded by the root is exceedingly small. As originally obtained it was very impure, probably in the condition of a salt, and in this state is directed by the French Codex. *Impure emetia* is in transparent scales of a brownish-red colour, almost inodorous, of a bitterish acrid state, deliquescent, very soluble in water and alcohol, insoluble in ether, precipitated from its solutions by gallic acid and the acetates of lead, but not by tartar emetic or the salts of iron. It is obtained by treating powdered ipecacuanha with ether to remove the fatty matter, exhausting the residue with alcohol, evaporating the alcoholic solution to dryness, and subjecting the extract to the action of cold water, which dissolves the emetia with some free acid, and leaves the wax and other matters. To separate the acid, the watery solution is treated with carbonate of magnesia, filtered, and then evaporated. If pure *emetia* is required, magnesia is used instead of the carbonate. The salt is thus decomposed, and the organic alkali being insoluble is precipitated with the excess of the earth. The precipitate is washed with cold water, and digested in alcohol, which dissolves the *emetia;* the alcoholic solution is then evaporated, the residue redissolved in a dilute acid, and the alkali again precipitated by a salifiable base. To deprive it of colour it is necessary to employ animal charcoal. Berzelius has obtained emetia by treating the powdered root with very dilute sulphuric acid, precipitating with magnesia, and treating the precipitate in the manner above directed. Pure emetia has at least three times the strength of the impure.

Medical Properties and Uses. Ipecacuanha is in large doses emetic, in smaller, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities insufficient to vomit, it produces nausea and frequently acts upon the bowels. As an emetic it is mild but tolerably certain in its operation, and being usually thrown from the stomach by one or two efforts, is less apt to produce dangerous effects when taken in an overdose than some other substances of the same class. It is also recommended by the absence of corrosive and narcotic properties.

It was employed as an emetic by the natives of Brazil, when that country was first settled by the Portuguese; but, though described in the work of Pison, it was not known in Europe till the year 1672, and did not come into use till some years afterwards. John Helvetius, grandfather of the celebrated author of that name, having been associated with a merchant who had imported a large quantity of ipecacuanha into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections, that general attention was attracted to it; and the fortunate physician received from Louis XIV. a large sum of money, and public honours, on the sole condition that he should make the remedy public. From this period it has maintained its standing among the most useful articles of the materia medica.

As an emetic it is peculiarly adapted by its mildness and efficiency to all cases in which the object is merely to evacuate the stomach, or a gentle impression only is desired; and in most other cases in which emetics are indicated, it may be advantageously combined with the more energetic medicines, the action of which it renders safer by insuring their discharge. It is especially useful where narcotic poisons have been swallowed, as under these circumstances it may be given in almost indefinite doses, with little comparative risk of injury to the patient. In dysentery it has been supposed to exercise peculiar powers; but is at present less used than formerly in doses sufficient to excite vomiting. As a nauseating remedy it is used in asthma, hooping cough, and the hemorrhages; as a diaphoretic, combined with opium, in a wide circle of diseases. (See *Pulvis Ipecacuanhæ et Opii.*) Its expectorant properties render it beneficial in catarrhal and other pulmonary affections. It has been given also, with supposed advantage, in very minute doses, in dyspeptic cases, and in chronic disease of the gastro-intestinal mucous membrane.

Ipecacuanha is most conveniently administered as an emetic in the form of powder suspended in water. The dose is about twenty grains, repeated if necessary at intervals of twenty minutes till it operates. Its operation may be facilitated and rendered milder by copious draughts of warm water or warm chamomile tea. An infusion in boiling water in the proportion of two drachms of the powder to six fluidounces of menstruum, may be given in the dose of a fluidounce repeated as in the former case. With a view to the production of nausea, the dose in substance may be two grains, given more or less frequently according to circumstances. As a diaphoretic it may be given in the quantity of a grain; as an alterative, in diseases of the stomach and bowels, of a quarter or half a grain two or three times a day.

Emetia has been used on the continent of Europe as a substitute, but with no great advantage. Its operation on the stomach is apt to be more violent and continued than that of ipecacuanha itself; and if given in overdoses, it may produce dangerous and even fatal consequences. From the experiments of Magendie, it appears to have a peculiar direction to the mucous membranes of the alimentary canal and the bronchial tubes. Ten grains of the impure alkali administered to dogs, were generally found to destroy life in twenty-four hours, and the mucous membranes mentioned were observed to be inflamed throughout their whole extent. The same result took place when emetia was injected into the veins, or absorbed from any part of the body. The dose of impure emetia is about a grain and a half, of the pure not more than half a grain, repeated at proper intervals till it vomits. In proportional doses it may be applied to the other purposes for which ipecacuanha is used. It will excite vomiting when applied to a blistered surface after the removal of the cuticle. Magendie found that dogs slept much after being vomited with emetia, and concluded that the medicine was narcotic; but other emetic medicines produce the same effect, which is to be ascribed rather to exhaustion than to any direct operation on the brain.

IPECACUANHAS NOT OFFICINAL.

When ipecacuanha began to be popular in Europe, the roots of several other plants were imported and confounded with the genuine, and the name came at length to be applied to almost all emetic roots derived from the American continent. Several of these are still occasionally found in commerce, and retain the name originally applied to them. The two most worthy of notice are the ipecacuanha of New Granada and Peru, and the white ipecacuanha of Brazil. On each of these we shall offer a few remarks.

1. *Peruvian Ipecacuanha.*—This is the root of the *Psychotria emetica*, formerly supposed to produce the genuine Brazilian ipecacuanha. The plant, like the Cephaëlis, belongs to the class and order Pentandria Monogynia, and to the natural order Rubiaceæ of Jussieu. A description of it sent by Mutis was published by Linnæus the younger in his supplement. It has since been described in the *Plant. Æquinox.*; and has been figured by A. Richard in his History of the Ipecacuanhas, and by Hayne in the eighth volume of his Medical Botany published at Berlin. It is a small shrub, with a stem twelve or eighteen inches high, simple, erect, round, slightly pubescent, and furnished with opposite, oblong lanceolate, pointed leaves, narrowed at their base into a short petiole, and accompanied with pointed stipules. The flowers are small, white, and supported in small clusters towards the end of an axillary peduncle. The plant flourishes in Peru and New Granada, and was seen by Humboldt and Bonpland growing in abundance near the river Magdalena. The dried root is exported from Carthagena.

It is cylindrical, somewhat thicker than the root of the Cephaëlis, usually simple, but sometimes branched, not much contorted, wrinkled longitudinally, presenting here and there deep circular intersections, but without the annular rugæ of the true ipecacuanha. The longitudinal direction of the wrinkles has given origin to the name of *striated ipecacuanha*, by which it is known in French Pharmacy. It consists of an internal woody chord and an external cortical portion; but the former is usually larger in proportion to the latter than in the root of the Cephaëlis. The bark is soft and easily cut with a knife, and when broken exhibits a brown slightly resinous fracture. The epidermis is of a dull reddish-gray colour, which darkens with age and exposure, and ultimately becomes almost black. Hence the root has sometimes been called *black ipecacuanha*. The ligneous portion is yellowish, and perforated with numerous small holes visible by the microscope. The Peruvian ipecacuanha is nearly inodorous, and has a flat taste, neither bitter nor acrid. Out of 100 parts Pelletier obtained 9 of impure emetia, 12 of fatty matter, with an abundance of starch, besides gum and lignin. The dose, as an emetic, is from two scruples to a drachm.

2. *White Ipecacuanha.*—This variety was noticed in the work of Pison, but the vegetable which produced it was not satisfactorily ascertained till a recent date. Gomez, indeed, in the memoir which he published at Lisbon, A.D. 1801, gave a figure and description of the plant; but the memoir was not generally known, and botanists remained uncertain upon the subject. By the travels of M. Saint-Hilaire and Dr. Martius in Brazil, more precise information has been obtained; and the white ipecacuanha is now confidently referred to different species of *Richardsonia*, the *Richardia* of Linnæus. The *R. scabra*, or *R. Braziliensis* of Gomez, and the *R. emetica* are particularly indicated by Martius, who also states that different species of *Ionidium* (Ventinat), *Viola* (Linn.), produce what is called *white ipecacuanha*. The name of *undulated ipecacuanha* is proposed by Guibourt for this variety, from the peculiar character of the surface, which presents indentations or concavities on one side, corresponding with prominences or convexities on the other, so as to give a wavy appearance to the root. It differs little in size from the genuine; is of a whitish-gray colour externally; and when broken presents a dull white farinaceous fracture, offering by the light of the sun, shining points, which are nothing more than small grains of fecula. Like the other varieties it has a woody centre. It is inodorous and insipid, and contains, according to Pelletier, a very large proportion of starch, with only six per cent. of impure emetia, and two of fatty matter. Richard found only 3.5 parts of emetia in the hundred. It is said to be sometimes mixed with the genuine ipecacuanha; but we have discovered none in the bales which we have examined.* W.

---

* See a paper on Ipecacuanha by R. E. Griffith, M. D., in the Journ. of the Phil. Col. of Pharm. Vol. 3. p. 181, for a more extended account of the roots which have been used under the name of Ipecacuanha.

In all the species belonging to this genus, so far as examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, the *I. fœtidissima*, *I. Florentina*, *I. Germanica*, *I. pseudo-acorus*, and *I. tuberosa* have at various times been admitted into use. Of these the *I. Florentina* is the only one acknowledged by the British or American Pharmacopœias.

Iris Florentina. Willd. *Sp. Plant.* i. 226; Woodv. *Med. Bot.* p. 776. t. 262. The root of the Florentine Iris is perennial, horizontal, tuberous, fleshy, fibrous, and covered with a brown epidermis. The leaves spring directly from the root, are sword-shaped, pointed, nerved, and shorter than the stem, which rises from the midst of them more than a foot in height, round, smooth, jointed, and bearing commonly two large white or bluish-white terminal flowers. The calyx is a spathe with two valves. The corolla divides into six segments or petals, of which three stand erect, and the remaining three are bent backward, and bearded within at their base with yellow-tipped white hairs. The fruit is a three-celled capsule, containing numerous seeds.

This plant is a native of Italy, and other parts of the South of Europe. The root, which is the officinal portion, is dug up in spring, and prepared for the market by the removal of its cuticle and fibres. It is brought from Leghorn in large casks.

Properties. The Florentine orris is in pieces of various form and size, often branched, usually about as thick as the thumb, knotty, flattened, white, heavy, of a rough though not fibrous fracture, a pleasant odour resembling that of the violet, and a bitterish acrid taste. The acrimony is greater in the recent than in the dried root; but the peculiar smell is more decidedly developed in the latter. The pieces are brittle and easily powdered, and the powder is of a dirty white colour. Vogel obtained from Florentine orris, gum, a brown extractive, fecula, a bitter and acrid fixed oil or soft resin, a volatile crystallizable oil, and vegetable fibre.

Medical Properties. This medicine is cathartic, and in large doses emetic, and was formerly employed to a considerable extent on the continent of Europe. It is said also to be diuretic, and to have proved useful in dropsies. At present it is chiefly valued for its pleasant odour. It is occasionally chewed to conceal an offensive breath, and enters into the composition of numerous tooth-powders. It is one of the ingredients of the *Emplastrum Plumbi Carbonatis* of the United States Pharmacopœia. In the form of small round balls, about the size of a pea, it is much used by the French for maintaining the discharge from issues, a purpose to which it is adapted not only by its odour, but also by the slight degree of acrimony which it retains in its dried state, and by the property of swelling very much by the absorption of moisture.

IRIS VERSICOLOR. *U.S. Secondary.*

Blue Flag.

"Iris versicolor. Radix. *The root.*" *U.S.*

IRIS. See IRIS FLORENTINA.

Iris versicolor. Willd. *Sp. Plant.* i. 233; Bigelow, *Am. Med. Bot.* i. 155. This indigenous species of Iris has a perennial, fleshy, horizontal, fibrous root, and a stem two or three feet high, round on one side, acute on the other, and frequently branching. The leaves are sheathing at the base, sword-shaped, and striated. The flowers are from two to six in number, and are usually blue or purple, though varying much in colour. The capsule has three valves, is divided into three cells, and when mature is oblong, three-sided, with obtuse angles, and contains numerous flat seeds.

The blue flag is found in all parts of the United States, flourishing in low wet places, in meadows, and on the borders of swamps, which it serves to adorn with its large and beautiful flowers. These make their appearance in June. The root is the medicinal portion. The flowers afford a fine blue infusion, which serves as a test of acids and alkalies.

The recent root is without odour, and has a nauseous, extremely acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol. The acrimony as well as medicinal activity is impaired by age.

The blue flag possesses the cathartic, emetic, and diuretic properties common to most of the species of this genns. It is said by Mr. Bartram to be held in much esteem by the Southern Indians; and Dr. Bigelow informs us that he has found it efficacious as a purgative, though inconvenient from the distressing nausea and prostration which it is apt to occasion. Dr. Macbride of Carolina found it useful in dropsy. It is, however, very little employed by the profession at large, and is seldom if ever kept in the shops. It may be given in substance, decoction, or tincture. The dose of the dried root is from ten to twenty grains. W.

◆

JALAPA. *U.S.*

Jalap.

"Ipomœa Jalapa, *Coxe;* Convolvulus Jalapa, *Willdenow.* Radix. *The root.*" *U. S.*

Off. Syn. JALAPÆ RADIX. Convolvulus Jalapa. Radix. *Lond.;* CONVOLVULI JALAPÆ RADIX. *Ed.;* JALAPA. CONVOLVULUS JALAPA. Radix. *Dub.*

Jalap, *Fr.;* Jalappen-Wurzel, *Germ.;* Sciarappa, *Ital.;* Jalapa, *Span.*

The precise botanical character of the jalap plant has long been a matter of much uncertainty. Linnæus, following Clusius, Plumier, Tournefort, and others, at first referred it to the *Mirabilis*, but subsequently adopting the opinion of Ray and Miller, was led to consider it a *Convolvulus*, and named it accordingly *C. Jalapa*, a title by which it has since been generally described in botanical and medical works. Thierry de Menonville, who in 1777 was in that part of Mexico where the plant flourishes, soon afterwards described a vegetable which he found in the neighbourhood of the city of Vera Cruz, and which he supposed to be identical with that which yields jalap. His description was found to correspond exactly with the character of a plant which Michaux the elder had sent from Charleston, South Carolina, to the Botanical Garden at Paris, and which he had described under the name of *Ipomœa macrorhiza.* This was figured by Desfontaines, and thought by many to be the true jalap plant; and as the *I. macrorhiza* grows in Georgia and Florida, it was inferred that this valuable drug was produced within the limits of the United States. Pursh was so convinced of the identity of the jalap of Mexico with the *I. macrorhiza* of Michaux, that he conferred upon the latter the title of *Ipomœa Jalapa.* But there are several circumstances which tend to prove that the two plants have been improperly confounded. The simple fact that the *I. macrorhiza* has a root which weighs from fifty to sixty pounds, is sufficient to prove that it cannot be the source of the officinal jalap, of which the dried tubers as they reach us are very seldom larger than the fist, and the slices could by no possibility be derived from a root of very great magnitude. Besides, the root of the *I. macrorhiza* was ascertained by Dr. Baldwin to possess little or no purgative power; and another striking dissimilarity between this plant and the true jalap, is that the leaves of the former are downy on their under surface, while there is every reason to believe that those of the latter are perfectly smooth; for a plant raised by Miller from seeds sent from Mexico by Dr. Houston, who was well acquainted with the true jalap, is described in the sixth edition of the Gardener's Dictionary as having smooth leaves; and the same fact is stated of the plant by M. Ledanois in a recent communication transmitted from Mexico to Paris. Thierry de Menonville was, therefore, in all probability mistaken in considering as the jalap plant, that found by him in the vicinity of Vera Cruz; and his mistake has been the source of numerous errors in subsequent writers. It is thought by some that his plant, and consequently the *I. macrorhiza*, is the source of the *mechoacan*, a purgative root also brought from Mexico, and sometimes mixed with the jalap; but the fact has not been well ascertained. The question now recurs, what is the jalap plant? Is it a Convolvulus as generally supposed, or is it an Ipomœa? These two genera are closely allied, the most striking difference being in the character of the *stigma*, which in the Convolvulus is double, in the Ipomœa, according to Elliott, simple and capitate. Some botanists place in the latter genus those Convolvuli which have divided but capitate stigmas, retaining in the former those only in which this organ is filiform. Nuttall, however, follows Elliott, and on this side of the Atlantic, the authority of these two botanists may be considered as decisive. According to this arrangement the plant of Michaux is a *Convolvulus*. There is good reason to believe that the jalap plant is an *Ipomœa*. That figured and described by Woodville under the name of *Convolvulus Jalapa*, the description of which was copied by Dr. Thomson in his Dispensatory, was introduced into the royal garden at Kew, in 1778, by M. Thouin; but we have no evidence that it is the true jalap, and Nuttall thinks it resembles more closely the *Convolvulus panduratus*. In the year 1827, Dr. John R. Coxe, Professor of Materia Medica in the University of Pennsylvania, received directly from Xalappa several small jalap plants in a growing state; and having placed them in his garden, succeeded in raising one with all the parts necessary for a decision upon its botanical character. Mr. Nuttall, to whom it was exhibited, had no hesitation in pronouncing it an Ipomœa, and described it with the title of Ipomœa Jalapa. This title is recognised in the United States Pharmacopœia. The British Colleges still refer the drug to the Convolvulus Jalapa.

IPOMŒA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Convolvulaceæ.

Gen. Ch. *Calyx* five-cleft. *Corolla* funnel-form or campanulate, five-plaited. *Stigma* capitate, globose. *Capsule* two or three-celled, many-seeded. *Nuttall.*

Ipomæa Jalapa. Nuttall, *Am. Journ. Med. Sciences*, v. 300. The root of this plant is a roundish somewhat pearshaped tuber, externally blackish, internally white, with long fibres proceeding from its lower part as well as from the upper root-stalks. A tuber raised by Dr. Coxe was in its third year between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighbouring objects, about which it twines. The leaves are heart-shaped, entire, smooth, pointed, deeply sinuated at the base, prominently veined on their under surface, and supported upon long footstalks. The lower leaves are nearly hastate, or with diverging angular points. The flowers, which are large and of a lilac-purple colour, stand upon peduncles about as long as the petioles. Each peduncle supports two, or more rarely three flowers. The calyx is without bractes, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate. The above description is taken from that drawn up by Mr. Nuttall, and published in Dr. Coxe's paper in the American Journal of the Medical Sciences.

The jalap plant is a native of Mexico, and derived its name from the city of Xalappa, in the state of Vera Cruz. It might undoubtedly be cultivated in the southern section of the United Sates; as the offset of the root planted by Mr. Nuttall so far north as Cambridge, Massachusetts, survived the winter, and produced in the following season a vigorous plant. Jalap is brought from the port of Vera Cruz in bags containing usually between one hundred and two hundred pounds.

Properties. The tuber comes either whole, or divided longitudinally into two parts, or in transverse circular slices. The entire tubers are irregularly roundish, or ovate and pointed, or pear-shaped, usually much smaller than the fist, and marked with circular or vertical incisions, made to facilitate their drying. In this state, the root is preferred, as it is less apt to be defective, and is more easily distinguished from the adulterations than when sliced. A much larger proportion comes in this shape than formerly, indicating a greater scarcity of the older roots, which it is necessary to slice in order to dry them properly. The tuber is heavy, compact, hard, brittle, with a shining undulated fracture, exhibiting numerous resinous points, distinctly visible by the microscope. It is externally brown and wrinkled, internally of a grayish colour, diversified by concentric darker circles, in which the matter is denser and harder than in the intervening spaces. It is always kept in the shops in the state of powder, which is of a yellowish-gray colour, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing. The odour of the root, when cut or broken, is heavy, sweetish, and rather nauseous; the taste is sweetish, somewhat acrid, and disagreeable. It yields its active properties partly to water, partly to alcohol, and completely to diluted alcohol. M. Cadet de Gassicourt obtained from 500 parts of jalap, 24 of water, 50 of resin, 220 of gummy extract, 12.5 of fecula, 12.5 of albumen, 145 of lignin, 16.3 of saline matters, 2.7 of silica, with a loss of 17 parts. The *jalapin* of Mr. Hume has proved to consist of inorganic salts. The resin of jalap consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The proportion of resin to the other ingredients of the root varies considerably in different specimens. According to Gerber, the root contains 7.8 per cent. of hard resin, 3.2 of soft resin, 17.9 of extractive, 14.5 of gummy extract, 8.2 of a colouring substance which becomes red under the influence of the alkaline carbonates, 1.9 of uncrystallizable sugar, 15.6 of gum mixed with some saline matters, 3.2 of bassorin, 3.9 of albumen, 6.0 of starch, 8.2 of lignin, with some water, and various salts.

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin; so that the worm-eaten drug is more powerfully purgative than that which is sound. Thus out of 397 parts of the former M. Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence worm-eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength.

Adulterations. Jalap is said to be sometimes adulterated with *bryony root;* but no instance of the kind has come under our notice; and the two drugs are so widely different that the fraud would be instantly detected. This must be at once evident from the following description of bryony root, which we copy from Fée's work on the Natural History of Drugs. "Root spindle-shaped, about a foot long and nearly six inches in diameter, usually branching, obtuse, rounded at the top, of a yellowish-white colour, rough, with close transverse wrinkles, and a white, fleshy, succulent parenchyma."* It is probable, however, that the adulteration which has been considered as bryony root, is the *mechoacan*, which in Europe, is sometimes called American bryony, and was formerly erroneously supposed to be derived from a species of Bryonia. The *mechoacan* is a product of Mexico, which was taken to Europe even before the introduction of jalap. We have before stated that the plant which produces it is probably identical with the *Ipomœa macrorhiza* of Michaux, the *Convolvulus macrorhizus* of some other authors. According to M. Fée, it is in "fragments of various forms, or in whitish slices, which are fibrous, softish, invested with a grayish and rough bark, solid, white, or yellowish-white internally." This description answers very closely to the characters of a drug known in our markets as spurious jalap, which often comes mingled with the genuine, and has sometimes been imported unmixed in mistake for that root. Whether it is really the mechoacan we are unable to decide with certainty, as it is not known by that name to our merchants. It always comes in slices, which are evidently portions of a large, and probably a spindle-shaped root. The shape of the greater number of pieces indicates that the root was sliced transversely, and each circular slice divided into quarters. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in the drying process of some parts than others, and presents the extremities of numerous fibres, which are often concentrically arranged, and run in the longitudinal direction of the root. Internally the colour is whitish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous. The taste, like that of mechoacan, is at first insensible, but after some time becomes somewhat acrid and nauseous. The mechoacan is truly an adulteration, as its purgative powers are very feeble.

Mixed with jalap are also sometimes found transverse circular slices about the size of those of columbo root, with a uniform, white, amylaceous parenchyma, between which and the bark is a very evident line of division. Whether these are derived from the same or a different plant we are unable to decide. They are evidently destitute, or nearly so, of the resinous constituent of jalap, and should be rejected.

It is not impossible that portions of the root of a plant called in Mexico *male jalap*, may sometimes be mixed with the genuine drug. According to M. Ledanois this root is spindle-shaped, and sometimes twenty inches long.

Jalap should be rejected when it is light, of a whitish colour internally, of a dull fracture, spongy, or friable.

---

* The plant producing this root is the *Bryonia alba*, figured and described in Woodville's Med. Bot. page 194. The root was formerly among the medicines directed by the Edinburgh College. As prepared for the shops, it was usually in transverse slices. It is a powerful, irritating, hydragogue cathartic, said to be diuretic in small doses; but has been abandoned in consequence of its uncertainty and occasional harshness.

Medical Properties and Uses. Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The watery extract obtained from jalap previously exhausted by rectified alcohol, is said to have no cathartic effect, but to operate powerfully by urine. (*Duncan.*) The alcoholic extract, usually called resin of jalap, purges actively and often produces severe griping. From these facts it appears, that the virtues of this cathartic do not depend exclusively upon any one principle. Jalap was introduced into Europe in the latter part of the sixteenth, or beginning of the seventeenth century, and now ranks among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of dropsy. It is generally given in connexion with other medicines which assist or qualify its operation. In dropsical complaints it is usually combined with the supertartrate of potassa; and the same mixture is much employed in the treatment of the hip disease, and scrofulous affections of other joints. With calomel its forms a cathartic compound, which has long been highly popular in the United States in bilious fever, and other complaints attended with congestion of the liver or portal circle.

The dose of jalap in powder is from fifteen to thirty grains; of the resin or alcoholic extract, which is much used on the continent of Europe, from four to eight grains. The latter is usually given rubbed up with sugar, or in emulsion, by which its tendency to irritate painfully the mucous membrane of the bowels is thought to be in some measure obviated. The extract of the United States and British Pharmacopœias is preferable to the alcoholic, as it more completely represents the jalap itself. The dose of calomel and jalap is ten grains of each, that of the supertartrate of potassa and jalap, two drachms of the former and ten or fifteen grains of the latter.

Juglans cinerea. Willd. *Sp. Plant.* iv. 456; Bigelow, *Am. Med. Bot.* ii. 115.—*J. Cathartica.* Michaux, *N. Am. Sylva.* i. 160. This is an indigenous forest tree, known in different sections of the country by the various names of *butternut*, *oilnut*, and *white walnut*. In favourable situations it attains a great size, rising sometimes fifty feet in height, with a trunk three or four feet in diameter at the distance of five feet from the ground. The stem divides, at a small distance from the ground, into numerous nearly horizontal branches, which spread widely, and form a large tufted head, giving to the tree a peculiar aspect. The young branches are smooth and of a grayish colour, which has given origin to the specific name of the plant. The leaves are very long, and consist of seven or eight pairs of sessile leaflets, and a single petiolate leaflet at the extremity. These are two or three inches in length, oblong-lanceolate, rounded at the base, acuminate, finely serrate, and somewhat downy. The male and female flowers are distinct upon the same tree. The former are in large aments, four or five inches long, hanging down from the sides of the shoots of the preceding year's growth near their extremity. The fertile flowers are at the end of the shoots of the same spring. The germ is surmounted by two large, feathery, rose-coloured stigmas. The fruit is sometimes single, suspended by a thin pliable peduncle; sometimes several are attached to the sides and extremity of the same peduncle. The drupe is oblong-oval, with a terminal projection, hairy, viscid, green in the immature state, but brown when ripe. It contains a hard, dark-coloured, oblong, pointed nut, with a rough deeply and irregularly furrowed surface. The kernel is thick, oily, and pleasant to the taste.

The butternut grows in Upper and Lower Canada, and throughout the whole northern, eastern, and western sections of the United States. In the Middle States, the flowers appear in May, and the fruit ripens in September. The tree, if pierced immediately before the leaves unfold, yields a richly saccharine juice, from which sugar may be obtained nearly if not quite equal to that from the sugar-maple. The wood, though neither strong nor compact, is useful for some purposes on account of its durability, and exemption from the attacks of worms. The fruit, when half grown, is sometimes made into pickles, and when ripe, affords, in its kernel, a grateful article of food. The bark is used for dyeing wool a dark brown colour, though inferior for this purpose to that of the black walnut. It is said, when applied to the skin, to have a rubefacient effect. The inner bark is the medicinal portion, and that of the root, being considered most efficient, is directed by the national Pharmacopœia. It should be collected in May or June.

On the living tree, the inner bark when first uncovered is of a pure white, which becomes immediately on exposure a beautiful lemon colour, and ultimately changes to deep brown. It has a fibrous texture, a feeble odour, and a peculiar, bitter, somewhat acrid taste. Its medical virtues are entirely extracted by boiling water. Dr. Bigelow could detect no resin among its constituents; and the presence of tannin was not evinced by the test of gelatin, though a brownish-black colour was produced by the sulphate of iron.

Medical Properties and Uses. Butternut is a mild cathartic, operating without pain or irritation, and resembling rhubarb in the property of evacuating without debilitating the alimentary canal. It was much employed during our revolutionary war by Dr. Rush and other physicians attached to the army, and was highly esteemed. It is especially applicable to cases of habitual costiveness and other bowel affections, particularly dysentery, in which it has acquired considerable reputation. In connexion with calomel it becomes more active, and is sometimes used in our intermittent and remittent fevers, and other complaints attended with congestion of the abdominal viscera. It is given in the form of decoction or extract, never in substance. The extract is officinal, and is almost always preferred. The dose is from twenty to thirty grains as a purge, from five to ten grains as a laxative.

Juniperus communis. Willd. *Sp. Plant.* iv. 853; Woodv. *Med. Bot.* p. 13. t. 6. This is an erect evergreen shrub, usually small, but sometimes attaining a height of twelve or fifteen feet, with numerous very close branches. The leaves are narrow, longer than the fruit, entire, sharply pointed, channeled, of a deep green colour, somewhat glaucous on their upper surface, spreading, and attached to the stem or branches in threes, in a verticillate manner. The flowers are diœcious and disposed in small, ovate, axillary, sessile, solitary aments. The fruit is a globular berry, formed of the fleshy coalescing scales of the ament, and containing three angular seeds.

The common juniper is a native of Europe; but has been introduced into this country, in some parts of which it has become naturalized. It is not uncommon in the neighbourhood of Philadelphia. The plant described in Bigelow's American Medical Botany under the title of *J. communis*, deserves, perhaps, to be considered a distinct species. It is a trailing shrub, seldom rising more than two or three feet in height, spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. The name of *J. depressa* has been proposed for it. The common juniper flowers in May; but does not ripen its fruit till late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavour. The wood has a slight aromatic odour, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with *sandarach*, which is in fact the product of the *Thuya articulata.* The fruit and tops of juniper are the only officinal parts.

The berries are sometimes collected in this country, and parcels are occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the South of Europe, particularly from Trieste and the Italian ports. They are globular; more or less shrivelled; about as large as a pea; marked with three furrows at the summit, and with tubercles from the persistent calyx at the base; covered with a glaucous bloom, beneath which they are of a shining blackish-purple colour; and containing a brownish-yellow pulp and three angular seeds. They have an agreeable somewhat aromatic odour, and a sweetish, warm, bitterish, slightly terebinthinate taste. These properties, as well as their medical virtues, they owe chiefly to an essential oil which may be separated by distillation. (See *Oleum Juniperi.*) The other ingredients, according to Trommsdorff, are resin, sugar, gum, wax, lignin, water, and various saline substances. The proportion of these ingredients varies according to the greater or less maturity of the berries. The volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter, Trommsdorff found one per cent. of the oil. In those which are perfectly ripe it has been partly changed into resin, and in those quite black, completely so. The berries impart their virtues to water and alcohol. They are very largely consumed in the preparation of gin.

The tops of juniper are directed by the London and Dublin Colleges. Their odour is balsamic, their taste resinous and bitterish; and they possess similar virtues with the berries.

Medical Properties and Uses. Juniper berries are gently stimulant and diuretic, imparting to the urine the smell of violets; and producing occasionally, when very largely taken, disagreeable irritation in the urinary passages. They are chiefly used as an adjuvant to more powerful diuretics in dropsical complaints; but have been recommended also in scorbutic and cutaneous diseases, catarrh of the bladder, and atonic conditions of the alimentary canal and uterus. They may be given in substance triturated with sugar, in the dose of one or two drachms repeated three or four times a day. But the infusion is a more convenient form. It is prepared by macerating an ounce of the bruised berries in a pint of boiling water, the whole of which may be taken in the course of twenty-four hours. Extracts are prepared from the berries, both bruised and unbruised, and given in the dose of one or two drachms; but in consequence of the evaporation of the essential oil, they are probably not stronger than the berries in substance.

JUNIPERUS VIRGINIANA. *U.S. Secondary.*

Red Cedar.

"Juniperus Virginiana. Folia. *The leaves.*" *U.S.*

Juniperus. See JUNIPERUS.

Juniperus Virginiana. Willd. *Sp. Plant.* iv. 853; Bigelow, *Am. Med. Bot.* iii. 49; Michaux, *N. Am. Sylv.* iii. 221. This species of juniper, known commonly by the name of *red cedar*, is an evergreen tree of slow growth, seldom attaining a very large size, though sometimes rising forty or fifty feet in height, with a stem twelve or thirteen inches in diameter. It has numerous very close branches, which, in the young tree, spread out horizontally near the ground; but as the tree advances, the lower branches slowly decay, leaving the trunk irregular with knots and crevices. The leaves are very small, fleshy, ovate, concave, pointed, glandular on their outer surface, either ternate or in pairs, and closely imbricated. Those of the young shoots are often much longer, and spreading. The leaves closely invest the extreme twigs, increasing with their growth, till ultimately lost in the encroachments of the bark. "The barren flowers are in oblong aments, formed by peltate scales with the anthers concealed within them. The fertile flowers have a proper perianth, which coalesces with the germ, and forms a small, roundish berry, with two or three seeds, covered on its outer surface with a bright blue powder." (*Bigelow.*)

The red cedar grows in all latitudes of the United States, from that of Burlington in Vermont, to the Gulf of Mexico; but is most abundant and of most vigorous growth in the southern section, and within a short distance of the ocean. The interior wood is of a reddish colour, and highly valuable on account of its great durability. Small excrescencies which are sometimes found on the branches of the tree, are popularly used as an anthelmintic under the name of *cedar apples*. The leaves only are officinal.

They have a peculiar not unpleasant odour, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in an essential oil, and are readily imparted to alcohol. The tincture is rendered turbid by the addition of water; and the presence of tannin in the leaves is indicated by the usual tests.

The leaves of the *J. Virginiana* bear a close resemblance to those of the *J. Sabina*, from which they can be certainly distinguished only by the difference of odour.

Medical Properties and Uses. The resemblance of red cedar to savine is said also to extend to their medical properties; the former being considered, like the latter, stimulant, emmenagogue, diuretic, and, under certain circumstances, diaphoretic. It is, however, much less energetic; and though advantage may, as has been asserted, have accrued from its use in amenorrhœa, chronic rheumatism, and dropsy, it has not acquired the confidence of the profession generally. Externally applied it acts as an irritant; and an ointment prepared by boiling the fresh leaves for a short time in twice their weight of lard, with the addition of a little wax, is employed as a substitute for savine cerate in maintaining a purulent discharge from blistered surfaces. Sometimes the dried leaves in powder are mixed with six times their weight of resin cerate, and used for a similar purpose. But neither of these preparations is as effectual as the analogous preparations of savine. W.

KINO. *U.S., Lond., Ed., Dub.*

Kino.

"Nauclea gambir, et Pterocarpus erinacea. Extractum. *The extract.*" *U.S.*

Kino, *Fr., Germ., Ital.;* Quino, *Span.*

The term kino was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Dr. Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in their appearance and properties, have subsequently received the same name; and at present a confusion prevails in relation to the botanical and commercial history of the drug, which, in this country, cannot be satisfactorily settled. We shall present a view of the different varieties, as described in the works of highest authority on the materia medica.

1. *East India or Amboyna Kino.*—This is the kind which is said to be at present in most general use. It is thought to be the produce of the *Nauclea Gambir*, a twining East India shrub, belonging to the class and order *Pentandria Monogynia*, and the natural order *Rubiaceæ* of Jussieu; and described minutely by Mr. Hunter in the ninth volume of the London Linnean Transactions. This plant is a native of Malacca and the island of

Sumatra, where an extract is prepared from the young twigs and leaves, which is called *gutta gambeer* in the East, and is supposed by authors generally to be the same with kino. But any one who will compare Mr. Hunter's account of this extract with the characters of the kino of commerce, will be led at least to doubt their identity; and if the latter be procured from the same plant, it must be by a different process. The name of *Amboyna*, conferred on the East India kino, implies that it is prepared in that island also. It is this variety with which our market is chiefly supplied. We obtain it either directly from India, or more commonly from London, where it is bought at the East India Company's sales.

It is in small, angular, deep brown, shining, brittle fragments, of a uniform consistence, appearing as though formed by the breaking down of larger masses of a dried extract. These fragments are easily pulverized, affording a lighter brown somewhat reddish powder, a portion of which resulting from their mutual attrition, is usually found interspersed among them. They are without smell. The taste is very rough and astringent, and at first bitter; but ultimately leaves an impression of sweetness upon the tongue. Water at 60° dissolves two-thirds of this variety of kino, forming a deep brown clear solution. Alcohol also dissolves the greater portion, and the resulting tincture, which is of a deep claret colour, is not rendered turbid by the addition of water. The aqueous infusion affords a brick-red precipitate with a solution of isinglass, and an olive-black precipitate with the persulphate of iron. (*Thomson's Dispensatory.*)

2. *West India, or Jamaica Kino.* The source of this variety is not known with certainty. Dr. Duncan was informed by Dr. Wright that it was obtained from the *Coccoloba uvifera*, or seaside grape. The late Dr. Murray of Edinburgh was told, as we are informed in his work on Materia Medica, that it was the extract of the mahogany wood. Dr. Thomson states in his Dispensatory that none of it is now to be procured. Some years since a thick reddish-brown liquid was imported into Philadelphia from the West Indies, which, when dried by exposure to the air in shallow vessels, or by heat, afforded an extract having all the properties of kino, for which it was sold by our druggists. The supply, however, is now nearly or quite exhausted. We are unable to say what was its precise source, or whether it was identical with the variety described as Jamaica kino in the British pharmaceutical works.

The Jamaica kino, from whatever plant it may be derived, is evidently an extract. According to Dr. Duncan, it is in large fragments, sometimes retaining the impression of the vessel in which it was dried; of a homogeneous appearance; of a resinous fracture, exhibiting small air bubbles; of a dark brown almost black colour, but in very thin splinters transparent, and of a ruby redness; affording when pulverized a reddish brown powder; crackling under the teeth when chewed; of a taste somewhat acid at first, afterwards bitter and astringent, and ultimately sweetish. The greater part of it is soluble both in water and alcohol.

3. *African Kino.* The original kino employed by Dr. Fothergill was known to be the produce of a tree growing in Senegal and the neighbouring countries on the western coast of Africa; but the precise character of the tree was not ascertained, until a specimen sent home by Mungo Park, during his last journey, enabled the English botanists to decide that it was the *Pterocarpus erinacea* of Lamarck and Poiret. The London College accordingly refers kino to this plant; but in so doing have overlooked the fact, that the drug now used is seldom or never brought from Africa.

This variety of kino " is in very small, irregularly shaped, shining, deep ruby-brown coloured fragments, and intermixed with small twigs and minute bits of wood, which are whitish on the inside. It is pulverulent, affording a dark chocolate or reddish-brown powder. It is inodorous, and insipid when first taken into the mouth; but after some time it imparts a slight degree of roughness, with a scarcely perceptible sweetness, to the palate, feels gritty between the teeth when chewed, and does not colour the saliva." (*Thomson's Dispensatory.*) According to Dr. Thomson, water at 60° dissolves more than half of it, forming a brick-red, rather turbid infusion, which is not clear at the end of twenty-four hours. Alcohol dissolves nearly two-thirds, forming a very deep-brown coloured tincture, and leaving a nearly colourless residuum. The African kino is thought to be the concrete juice of the tree, and not an extract.

4. *Botany Bay Kino.* This is the concrete juice of the *Eucalyptus resinifera*, or brown gum tree of New Holland, a lofty tree, belonging to the class and order *Icosandria Monogynia*, and the natural order *Myrtaceæ*. When the bark is wounded the juice flows very freely, and hardens in the air. According to Mr. White, a single tree is capable of furnishing five hundred pounds of kino in one year. (*White's Voyage.*) Duncan states that specimens of the juice have reached Great Britain in the fluid state. The Edinburgh College erroneously adopts the inspissated juice of the *Eucalyptus resinifera* as the officinal kino. In relation to this variety Dr. Duncan states that when he first examined kino in 1802, it was common, and was the finest kind in commerce. According to information received by Dr. Thomson, its importation into Great Britain must have ceased soon after that period. (*Thomson's Dispensatory*, Edit. 1826, p. 506.) Ainslie informs us that he has met with it in the markets of Hindostan. Parcels may occasionally reach this country; but by such complicated routes that their origin is unknown.

Dr. Duncan thus describes it. "It occurs in dark brown masses of various sizes, either smooth or rounded on the surface, or in fragments often covered with a reddish-brown powder, fracture resinous and very unequal, appearance sometimes homogeneous but sometimes heterogeneous, mixed with bits of twigs, leaves, &c.; splinters transparent, ruby red; no smell, scarcely crackling under the teeth, but sometimes gritty from the accidental mixture of sand; taste simply astringent, succeeded by sweetness, and, when long chewed, a portion adheres to the teeth; infusible and friable; powder reddish-brown." White states that only one-sixth of this kino is soluble in water; Guibourt found it wholly soluble with the exception of foreign matters; and Dr. Thomson informs us that water at 60° dissolves more than one-half. These gentlemen must have experimented with different substances. According to Dr. Duncan, alcohol dissolves the whole except impurities, and the tincture, with a certain proportion of water, lets fall a copious red precipitate, but with a large portion only becomes slightly turbid.*

General Properties. Kino is in small, irregular, somewhat angular, shining fragments, of a dark brown or reddish-brown colour, brittle, pulverizable, and affording a powder which is lighter coloured than the masses. It is without odour, and has a bitterish, highly astringent, and ultimately sweetish taste. It is not softened by heat. Cold water dissolves it partially, boiling water more largely, and the saturated decoction becomes turbid on cooling, and deposites a reddish sediment. Alcohol dissolves the greater portion. It consists chiefly of a peculiar modification of tannin, with extractive matter, and, in some of the varieties, a minute proportion of resin. According to Vauquelin it contains no gallic acid. Its aqueous solution is precipitated by gelatin, by soluble salts of iron, silver, lead, and antimony, by the permuriate of mercury, and by the sulphuric, nitric, and muriatic acids. The alkalies favour its solubility in water, but essentially change its nature, and destroy its astringent property. Reference should be had to these relations of kino in prescribing it.

---

* A drug has lately been brought into the market at Philadelphia, and sold in considerable quantities, under the name of kino, imported, as we are informed from Caraccas, but of unknown origin. It is in large masses of a very dark colour externally, of a deep reddish-brown internally, brittle, with an irregular but shining fracture, and readily breaking into small fragments, bearing some resemblance to those of the kino ordinarily found in the shops, but perhaps less angular. It is much mixed with impurities, but has a very astringent taste, and will probably be found to answer in practice the purposes of the medicine the name of which it has assumed. It is broken, for sale, by means of a mill, into small irregular pieces.

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Fortunately little injury can result from the substitution, as the medical virtues of the two extracts are very nearly the same.

Medical Properties and Uses. Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In diarrhœa not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favourite addition to the chalk mixture. It is also used in chronic dysentery when astringents are admissible; in leucorrhœa and diabetes; and in passive hemorrhages, particularly that from the uterus. It was formerly used in intermittent fever, but has given way to more efficient remedies.

It may be given in powder, infusion, or dissolved in diluted alcohol. The dose of the powder is from ten to thirty grains. The infusion, which is a very convenient form of administration, may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool. Aromatics may be added if deemed advisable. The dose is a fluidounce. The proportion of alcohol in a dose of the tincture, renders it frequently an unsuitable preparation.

Locally applied, kino is often productive of benefit. Its infusion is useful as an injection in leucorrhœa and obstinate gonorrhœa, and thrown up the nostrils we have found it very efficacious in suppressing hemorrhage from the Schneiderian membrane. A case of obstinate hemorrhage from a wound in the palate, after resisting various means, yielded to the application of powdered kino, which was spread thickly on lint, and pressed against the wound by the tongue. The powder is also a very useful application to indolent and flabby ulcers.

KRAMERIA. *U.S.*

Rhatany.

"Krameria triandra. Radix. *The root.*" *U.S.*

Off. Syn. KRAMERIÆ RADIX. Krameria triandra. Radix. *Lond.*; RHATANIA. KRAMERIA TRIANDRA. Radix et extractum. *Dub.*

Ratanhie, *Fr.*; Ratanhiawurzel, *Germ.*; Ratania, *Ital.*, *Span.*

KRAMERIA. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Polygaleæ.

Gen. Ch. *Calyx* none. *Corolla* four petalled; the superior nectary three-parted, and inferior two-leaved. *Berry* dry, echinated, one-seeded. *Willd.*

Krameria triandra. Ruiz and Pavon, *Flor. Peruv.* i. 61. The rhatany plant is a shrub having a long, much branched, and spreading root, of a blackish-red colour, with a round, procumbent, very dark coloured stem, divided into numerous branches, of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness with the young branches, on the sides of which they are placed. The flowers are lake-coloured, and stand singly on short peduncles at the axils of the upper leaves. There are only three stamens. The nectary consists of four leaflets, of which the two upper are spatulate, the lower roundish and much shorter: it does not correspond with the generic character of Willdenow, which was drawn from the *Krameria Ixina.* The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and furnished with one or two seeds.

This species of Krameria is a native of Peru, growing in dry argillaceous and sandy places, and abundant about the city of Huanuco. It flowers at all seasons, but is in the height of its bloom in October and November. The root is dug up after the rains.

The *K. Ixina*, growing in Hayti, and in Cumana on the South American continent, is said to afford a root closely analogous in appearance and properties to that of the Peruvian species; but the latter only is officinal.

The name *rhatany* is said to express, in the language of the Peruvian Indians, the creeping character of the plant.

We receive rhatany in pieces of various shapes and dimensions, some being simple, some more or less branched, the largest as much as an inch in thickness, being derived from the main body of the root, the smallest not thicker than a small quill, consisting of the minute ramifications. They are composed of a dark reddish-brown, slightly fibrous, easily separable bark, and a central woody portion less coloured, but still reddish, or reddish-yellow. The root is without smell, but has a bitter, very astringent, slightly sweetish taste, which is connected with its medical virtues, and is much stronger in the cortical, than the ligneous part. The smallest pieces are therefore preferable, as they contain the largest proportion of the bark. The powder is of a reddish colour. The virtues of the root are extracted by boiling water, which forms a dark brown infusion. By digestion in alcohol a deep reddish-brown tincture is obtained, from which a pink coloured precipitate separates upon the addition of water. From the researches of Vogel, Gmelin, Peschier, and Trommsdorff, the root appears to contain tannin, lignin, and minute quantities of gum, starch, saccharine matter, and an acid not well determined. The tannin is in three states; 1st. in that of purity, in which it is without colour, 2nd. that of apotheme, in which it has lost its astringency and been rendered insoluble by the action of the air, and 3rd. that of extractive, which is a soluble combination of tannin with its apotheme, and is the substance which imparts their characteristic reddish-brown colour to the infusion and tincture of rhatany. (Soubeiran, *Journ. de Pharm.* xix. 596.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of rhatany, and are incompatible in prescription.

By evaporating the decoction an extract is obtained, which when dried has a reddish-brown colour, a vitreous and shining fracture, and yields a blood-red powder. It has the bitterness and astringency of the root, and bears a close resemblance to kino. But the extract of rhatany is better prepared with officinal alcohol than by decoction; as during the boiling process, a considerable quantity of the pure tannin is converted into insoluble and inert apotheme, and another portion unites with the starch to form a compound insoluble in cold water, and of no medical efficacy. An extract prepared from the cold infusion, though smaller in amount, is proportionably even richer in active matter than the alcoholic, as the latter necessarily contains the inert apotheme of the root, which, though insoluble in water, is dissolved by alcohol. The extract imported from South America is much inferior to that prepared in our shops.

Medical Properties and Uses. Rhatany is gently tonic and powerfully astringent; and may be advantageously given in chronic diarrhœa, passive hemorrhages, some forms of leucorrhœa, and in all those cases in which kino and catechu are beneficial. It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. It has but recently been introduced into this country, where it is acquiring increased reputation. It has the advantage over the astringent extracts imported, that being brought in the state of the root, it is free from adulteration, and may be prescribed with confidence.

The dose of the powder is from twenty to thirty grains; but in this form the root is little used. The decoction is more convenient, and is usually preferred. It may be prepared by boiling an ounce of the bruised root in a pint of water, and taken in the dose of one or two fluidounces. The extract, when carefully made, is perhaps preferable to any other form, as it is of uniform strength. The dose is ten or fifteen grains. A tincture may be prepared by macerating three ounces of the bruised or powdered root in a pint of diluted alcohol for two weeks. Half an ounce of cinnamon or an ounce of orange-peel may be added to the other ingredients, to improve the flavour, and render the tincture more pleasant to the stomach. The dose is one or two fluidrachms. A syrup of rhatany is prepared by making a saturated cold infusion, and adding a sufficient quantity of sugar. It may be given to children in the dose of a teaspoonful. W.

LACTUCA ELONGATA. *U.S. Secondary.*

Wild Lettuce.

"Lactuca elongata. Planta. *The Plant.*" *U.S.*

Lactuca. *Sex. Syst.* Syngenesia Æqualis.—*Nat. Ord.* Compositæ Cichoraceæ.

Gen. Ch. Receptacle naked. *Calyx* imbricated, cylindrical, with a membranous margin. *Pappus* simple, stipitate. *Seed* smooth. *Willd.*

Lactuca elongata. Willd. *Sp. Plant.* iii. 1525. This indigenous species of lettuce is biennial, with a stem from three to six feet in height, and leaves of which the lower are runcinate, entire, and clasping, the lowest toothed, and the highest lanceolate. They are all smooth on their under surface. The flowers are in corymbose panicles, small, and of a pale yellow colour. The stem and leaves yield, when wounded, a milky juice in which the virtues of the plant reside.

The *wild lettuce* grows in all latitudes of the United States, from Canada to the Carolinas. It is found in woods, along roads, and in fertile soils, and flowers in June and July.

It was introduced into the secondary list of the U. S. Pharmacopœia as a substitute for the *Lactuca virosa* of Europe, which it is said to resemble somewhat in medical properties. Dr. Bigelow was informed by physicians who had employed it, that it acts as an anodyne, and promotes the secretion from the skin and kidneys. It is seldom used in regular practice.

An extract prepared by expressing and inspissating the juice of the fresh plant may be given in doses of from five to fifteen grains. (*Bigelow's Sequel.*) W.

Lactuca. See LACTUCA ELONGATA.

Lactuca virosa. Willd. *Sp. Plant.* iii. 1526; Woodv. *Med. Bot.* p. 75. t. 31. The strong-scented lettuce is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong, obovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bractes are cordate and pointed. The flowers are numerous, of a sulphur-yellow colour, and disposed in a panicle. The plant is lactescent, and has a strong disagreeable smell like that of opium, and a bitterish acrid taste. The inspissated expressed juice is the only part used in medicine. It should be prepared while the plant is in flower, as the milky fluid, upon which its virtues depend, is then most abundant. The strong-scented lettuce is a native of Europe.

Medical Properties and Uses. The extract or inspissated juice is a sedative narcotic, said also to be gently laxative, powerfully diuretic, and somewhat diaphoretic. It is employed in Europe, particularly in Germany, in the treatment of dropsy, and is especially recommended in cases attended with visceral obstruction. Dr. Collin of Vienna was very successful with it in the cure of this disease. It is usually, however, combined with squill, digitalis, or some other diuretic; and it is not easy to decide how much of the effect obtained is justly ascribable to the lettuce. The medicine is never used in this country. The dose is eight or ten grains, which may be gradually increased to a scruple or more. The *Lactuca Scariola*, another European species, possesses similar properties, and is used for the same purposes.

Lactuca. See LACTUCA ELONGATA.

Lactuca sativa. Willd. *Sp. Plant.* iii. 1523. The garden lettuce is an annual plant. The stem, which rises about two feet in height, is erect, round, simple below, and branching in its upper part. The lower leaves are obovate, rounded at the end, and undulating; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green colour. The flowers are pale yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland, pellucid juice, has little taste or smell, and is much used as a salad for the table; but during the period of inflorescence it abounds in a peculiar milky juice, which readily escapes from incisions in the stem, and has been found to possess decided medicinal as well as sensible properties. A similar juice is produced by all the other species of lettuce, and has in fact served as the origin of the title by which the genus is designated. This juice is more abundant in the wild than in the cultivated plants. That of the *L. sativa*, inspissated by exposure to the air, has been adopted as officinal by the Edinburgh College, and has found a place in the secondary catalogue of the United States Pharmacopœia, under the name of *Lactucarium.*

The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and is now employed in all parts of the civilized world. It flourishes equally well in hot and temperate latitudes. Some botanists suppose that the *L. virosa* of the old continent is the parent of all the varieties of the cultivated plant.

The milky juice undergoes little alteration, if confined in closely stopped bottles from which the air is excluded. But when exposed to the air, it concretes and assumes a brownish colour somewhat like that of opium. Mr. Young, of Edinburgh, recommends the following mode of collecting it. When the stem is about a foot high, the top is cut off, and the juice which exudes, being absorbed by cotton or a piece of sponge, is pressed out into a cup or other small vessel, and exposed till it concretes. In order to obtain all the juice which the plant is capable of affording, it is necessary to cut off five or six successive slices of the stem at short intervals, and to repeat the process two or three times a day. The juice may also be collected by the finger as it flows from the incisions. In its concrete state it bears a close resemblance to opium in colour, taste, and smell, and has sometimes been called lettuce opium. Its yields nearly half of its weight to water, with which it forms a deep brown infusion. From experiments made by Dr. Klink, assisted by Professor Pfaff of Kiel, the undissolved portion appears to consist of wax, resin, and caoutchouc. *Lactucarium* contains a free acid, and a peculiar narcotic principle; but is destitute of morphia. Procured in the manner above indicated, it is very expensive; and other modes have been proposed with a view to obviate this disadvantage.

A plan proposed by Mr. Probart of London, is to collect the milky juice on pieces of wove cotton about half a yard square, to throw these when fully charged into a vessel containing a small quantity of water, and allow the water thus impregnated to evaporate in shallow dishes at the ordinary temperature of the atmosphere. The lactucarium is left in the form of an extract, differing from the concrete juice chiefly in being destitute of caoutchouc. But prepared in this way also it is very expensive, in consequence of the smallness of the product.

Another method of extracting the virtues of the lettuce has been recommended by Mr. Probart. When the plant begins to assume a yellow hue, the white juice concretes in the bark of the stem, and in the old leaves, which become very bitter. These parts being separated, are macerated for twenty-four hours in water, then boiled for two hours; and the clear decoction, after having been allowed to drain off through a sieve without pressure, is evaporated in shallow vessels by simple exposure. The resulting extract, according to Mr. Probart, has half the strength of lactucarium, and may be obtained at one-sixth of the cost.

The London and Edinburgh Colleges direct an extract to be prepared by inspissating the expressed juice of the leaves; but this must be exceedingly uncertain, from the variable quantity of the milky juice contained in the plant; and as the young leaves, which contain little or none of it, are often employed, the preparation is liable to be quite inert. The proper lactucarium is greatly preferable.

Dr. Duncan erroneously states that the *thridace* of Dr. François is the expressed juice of lettuce. That practitioner employed the concrete milky juice obtained by incision.

Medical Properties and Uses. That lettuce possesses soporific properties, is a fact which was known to the ancients; but Professor Coxe, of Philadelphia, enjoys the credit of having first proposed the employment of its inspissated juice as a medicine. From experiments with a tincture prepared from lactucarium, or lettuce opium, as it has been called, Dr. Coxe obtained the same results as usually follow the administration of common laudanum. Dr. Duncan, senior, of Edinburgh, afterwards paid particular attention to the subject, and, in his treatise on pulmonary consumption, recommended lactucarium as a substitute for opium, the anodyne properties of which it possesses, without being followed by the same injurious effects. In consequence of this recommendation the medicine came into extensive use, and was adopted as officinal in several of the Pharmacopœias. Dr. François, a French physician, has also investigated, with great care, the medicinal properties of lactucarium. According to this author it is sedative in its action, diminishing the rapidity of the circulation, and consequently the temperature of the body, without producing that disturbance of the functions which often follows the use of opium. In this country the medicine is habitually employed by some practitioners to allay cough, and quiet nervous irritation.

The dose of lactucarium is two grains, to be repeated if necessary.

Water distilled from lettuce (*eau de laitue*) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasms. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use. (*Fée.*)

W.

LAURI BACCÆ ET FOLIA. *Lond.*

Berries and Leaves of the Bay Tree.

"Laurus nobilis. *Baccæ et Folia.*" *Lond.*

Off. Syn. LAURI NOBILIS BACCÆ. LAURI NOBILIS OLEUM EXPRESSUM. Ex Baccis. *Ed.;* LAURUS NOBILIS. Folia. Baccæ. *Dub.*

Laurier, *Fr.;* Lorbeer, *Germ.;* Allorg, *Ital.;* Laurel, *Span.*

Laurus. See CAMPHORA.

Laurus nobilis. Willd. *Sp. Plant.* ii. 479; Woodv. *Med. Bot.* p. 678. t. 235. This species of laurel is an evergreen tree, attaining in its native climate the height of twenty or thirty feet. Its leaves are alternate, on short petioles, oval lanceolate, entire, sometimes wavy, veined, of a firm texture, smooth, shining, deep green upon their upper surface, paler beneath. The flowers are diœcious, of a yellowish-white colour, and placed in small clusters of three or four together upon a common peduncle in the axils of the leaves. The corolla is divided into four oval segments. The fruit is an oval berry, of the size of a small cherry, and when ripe of a dark purple, nearly black colour.

The bay tree, so famous among the ancients, is a native of the countries bordering on the Mediterranean. Its leaves and fruit, and an oil expressed from the latter, are the officinal parts.

The leaves have a fragrant odour, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil, upon which their properties chiefly depend. Water distilled from them has their peculiar odour.

The berries when dried are black and wrinkled, and contain two oval, fatty seeds within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odour and taste as the leaves, but are more pungent. Besides an essential oil, they contain also a fixed oil, which may be separated by expression or decoction.

The expressed oil, which is obtained from the fresh fruit, is concrete, of a greenish colour, and retains a portion of the volatile oil, which renders it agreeably aromatic. Lard impregnated with the odorous principle of the berries, and coloured green, is said to be often substituted for the genuine expressed oil.

Medical Properties and Uses. The leaves, berries, and oil of the bay tree possess excitant and narcotic properties; but at present are never used internally as medicines, and in this country are scarcely employed in any manner. Their chief use is to communicate a pleasant odour to external stimulant remedies. Dr. A. T. Thomson says that he has found an infusion of the berries useful in impetigo. W.

LAVANDULA. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Calyx* ovate, somewhat toothed, supported by a bracte. *Corolla* resupine. *Stamens* within the tube. *Willd.*

Lavandula Spica. Willd. *Sp. Plant.* iii. 60; Woodv. *Med. Bot.* p. 321. t. 114.—*L. vera*, De Cand. *Flor. Fr. Sup.* p. 398. The *Lavandula Spica* of Linnæus includes two distinct species, which were considered by him merely as varieties of the same plant, but have been separated by subsequent botanists. Of these, the officinal plant, the narrow-leaved variety of Linnæus, has been denominated by De Candolle *L. vera*, while the broad-leaved variety still retains the title of *L. Spica.* It is the former which is intended by the Pharmacopœias, as the latter is scarcely cultivated in Great Britain or the United States.

The common lavender is a small shrub, usually rising not more than two or three feet, but sometimes attaining an elevation of six feet. The stem is woody below, and covered with a brown bark; above, is divided into numerous slender, straight, herbaceous, pubescent, quadrangular branches, furnished with opposite, sessile, narrow, nearly linear, entire, and green or glaucous leaves. The flowers are small, blue, and disposed in interrupted whorls around the young shoots, forming terminal cylindrical spikes. Each whorl is accompanied with two bractes. The corolla is tubular and labiate, with the lower lip divided into three segments, the upper larger and bifid. The filaments are within the tube.

The plant is a native of Southern Europe, and covers vast tracts of dry and barren land in Spain, Italy, and the South of France. It is cultivated abundantly in our gardens, and in this country flowers in August. All parts of it are endowed with properties similar to those for which the flowers are used; but these only are officinal. The spikes should be cut when they begin to bloom.

Lavender flowers have a strong fragrant odour, and an aromatic, warm, bitterish taste. They retain their fragrance a long time after drying. Alcohol extracts their virtues; and a volatile oil upon which their odour depends rises with that liquid in distillation. The oil may be procured separate by distilling the flowers with water. (See *Oleum Lavandulæ.*) Hagen obtained from a pound of the fresh flowers sometimes two drachms, sometimes only half a drachm of the oil.

Medical Properties and Uses. Lavender is an aromatic stimulant and tonic, esteemed useful in certain conditions of nervous debility, but very seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and as grateful additions to other medicines, which they render at the same time more acceptable to the palate and cordial to the stomach.

Lichen d'Islande, *Fr.;* Islandiches Moos, *Germ.;* Lichene Islandico, *Ital.;* Liquen Islandico, *Span.*

CETRARIA. *Sex. Syst.* Cryptogamia Lichenes.—*Nat. Ord.* Lichenes.

Gen. Ch. Plant cartilagino-membranous, ascending or spreading, lobed, smooth, and naked on both sides. *Apothecia* shield-like, obliquely adnate with the margin, the disk coloured, plano-concave; border inflexed, derived from the frond. *Loudon's Encyc.*

The genus *Lichen* of Linnæus has been divided by subsequent botanists into numerous genera, which have been raised to the dignity of a distinct order, both in the natural and artificial systems of arrangement. The name *Cetraria* was conferred by Acharius on the genus to which the Iceland moss belongs.

Cetraria Islandica. Acharius. *Lichenog. Univ.* 512.—*Lichen Islandicus.* Woodv. *Med. Bot.* p. 803. t. 271. Iceland moss is foliaceous, erect, from two to four inches high, with a dry, coriaceous, smooth, shining, laciniated frond or leaf, the lobes of which are irregularly subdivided, channeled, and fringed at their edges with rigid hairs. Those divisions upon which the fruit is borne are dilated. The colour is olive-brown or greenish-gray above, reddish at the base, and lighter on the under than the upper surface. The fructification is in flat, shield-like, reddish-brown receptacles, with elevated entire edges, placed upon the surface of the frond near its border.

The plant is found in the northern latitudes of the old and new continents; and on the elevated mountains further south. It received its name from the abundance in which it prevails in Iceland. It is also abundant on the mountains and in the sandy plains of New England.

The dried moss is of diversified colour, grayish-white, brown, and red in its different parts, with less of the green tint than in the recent state. It is inodorous, and has a mucilaginous, bitter taste. Macerated in water it absorbs rather more than its own weight of the fluid, and, if the water be warm, renders it bitter. Boiling water extracts all its soluble principles. The decoction thickens upon cooling, and acquires a gelatinous consistence, resembling that of starch in appearance, but without its viscidity. After some time the dissolved matter separates, and when dried forms semitransparent masses, insoluble in cold, but soluble in boiling water, from which it is precipitated by gallic acid. This principle resembles starch in its general characters, but differs from it in some respects, particularly in not being coloured blue by iodine. John considers it a modification of inulin. The most accurate analysis of Iceland moss is that by Berzelius. By this chemist 100 parts were found to afford 1.6 of chlorophylle, 3.0 of a peculiar bitter principle, 3.6 of uncrystallizable sugar, 3.7 of gum, 7.0 of the apotheme of extractive, 44.6 of the peculiar starch-like principle, 1.9 of the bilichenates of potassa and lime mixed with phosphate of lime, and 36.2 of amilaceous fibrin—the excess being 1.6 parts. (*Traité de Chim.* vi. 251.) The bitter principle is, when pure, pulverulent, light, yellow, inodorous, intensely bitter, slightly soluble in water, more so in alcohol, and freely soluble in the liquid alkalies.

The gum and starch contained in the moss render it sufficiently nutritive to serve as food for the inhabitants of Iceland and Lapland, who employ it powdered and made into bread, or boiled with milk, having first partially freed it from the bitter principle by repeated maceration in water. The bitterness may be entirely extracted by macerating the powdered moss, for twenty-four hours, in twenty-four times its weight of a solution formed with 1 part of an alkaline carbonate and 375 parts of water, decanting the liquid at the end of this time, and repeating the process with an equal quantity of the solution. The powder being now dried is perfectly sweet and highly nutritive. This process was suggested by Berzelius.

Medical Properties and Uses. Iceland moss is at the same time demulcent, nutritious, and tonic; and therefore well calculated for affections of the mucous membrane of the lungs and bowels, in which the local disease is associated with a debilitated condition of the digestive organs, or of the system generally. Hence it has been found useful in chronic catarrhs, and other pulmonary affections attended with copious and debilitating expectoration, especially when the matter discharged is of a purulent character; as also in dyspepsia, chronic dysentery, and diarrhœa. It has, moreover, been given in cases of debility succeeding acute disease, or dependent on copious purulent discharge from external ulcers. But the complaint in the treatment of which it has acquired most reputation is pulmonary consumption. It had long been employed in this disease, and in hæmoptysis, by the Danish physicians, before it became known to the profession at large. In the latter half of the last century it was introduced into extensive use; and numerous cases of cures supposed to have been effected by it are on record. But now that the pathology of consumption is understood, physicians have ceased to expect material advantage from it in the genuine tuberculous form of the disease; and there is reason to believe that the cases which have recovered under its use, were nothing more than chronic bronchitis or catarrh, or possibly ulceration dependent on ordinary inflammation of the pulmonary tissue. It can act only as a mild, nutritious, demulcent tonic; and certainly exercises no specific influence over tuberculous disease.

It is usually employed in the form of decoction. (See *Decoctum Lichenis.*) By some writers it is recommended to deprive it of the bitter principle by maceration in water, or a weak alkaline solution, before preparing the decoction; but we thus reduce it to the state of a simple demulcent, or mild article of diet, in which respect it is not superior to the ordinary farinaceous or gummy substances used in medicine. The powder is sometimes given in the dose of thirty grains or a drachm; and a preparation has obtained some repute, in which the ground moss is incorporated with chocolate, and used at the morning and evening meal as an ordinary beverage.

LIMON. *U.S.*

Lemons.

"Citrus medica. Fructus. *The fruit.*" *U. S.*

Off. Syn. LIMONES. Citrus medica. Baccæ. LIMONUM CORTEX.

Earum Cortex exterior. *Lond.;* CITRI MEDICÆ CORTEX. Cortex exterior Fructûs. CITRI MEDICÆ SUCCUS. Succus Fructûs. *Ed.;* LIMONES. CITRUS MEDICA. Fructûs succus, et tunica exterior. *Dub.*

Limons, Citrons, *Fr.;* Limonen, Citronen, *Germ.;* Limoni, *Ital.;* Limones, *Span.*

For some general remarks on the genus CITRUS, see the article *Aurantii Cortex.*

Citrus medica. Willd. *Sp. Plant.* iii. 1426; Woodv. *Med. Bot.* p. 528, t. 189. This tree closely resembles in its general aspect the *C. Aurantium* before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface; and the fruit is entirely different in appearance from the orange. There are several varieties of the *Citrus medica*, which some botanists consider entitled to the rank of species, but which are scarcely distinguishable, except by the character of their fruit. Those which are particularly deserving of notice are the citron, lemon, and lime. 1. In the citron, *C. medica* of Risso, the fruit is very large, sometimes six inches in length, ovoidal with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick, and spongy. It is divided in the interior into nine or ten cells, filled with oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves, to which it is adapted by its great thickness. This fruit is called *cedrat* by the French. 2. The lemon—*C. medica*, variety *limon* of Linnæus—the *Citrus Limonium* of Risso—is smaller than the preceding variety, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy and acid pulp. In other respects it bears a close resemblance to the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. 3. The lime is still smaller than the lemon, with a smoother and thinner rind, of an oval shape, rounded at the extremities, of a pale yellow or greenish-yellow colour, and abounding in a very acid juice, which renders it highly useful for all the purposes to which the lemon is applied. It is the product of the variety *C. acris* of Miller.

The *Citrus medica*, like the orange-tree, is a native of Asia. It was introduced into Europe from Persia or Media, was first cultivated in Greece, afterwards in Italy so early as the second century, and has now spread over the whole civilized world, being raised by artificial heat, where the climate is too cold to admit of its exposure with safety during winter to the open air.

We are supplied with lemons and limes chiefly from the West Indies and the Mediterranean. Though the former of these fruits only is directed by the United States Pharmacopœia, both kinds are employed indiscriminately for most medicinal purposes; and the lime affords a juice at least equal in proportional quantity, and in acidity, to that obtained from the lemon.

Properties. The exterior rind of the lemon has a fragrant odour, and a warm, aromatic, bitter taste, somewhat similar to that of the orange, though less agreeable. It yields, by expression or distillation, an essential oil which is much used for its flavour, and is recognised as officinal in all the Pharmacopœias. (See *Oleum Limonis.*) The British Colleges also adopt the rind itself, and that of Edinburgh directs a distilled water to be prepared from it. Lemon-peel yields its virtues to water, wine, and alcohol.

But the juice is the part for which this fruit is most esteemed. It is very sharply acid, with a peculiar grateful flavour, and consists chiefly of citric acid, mucilage, and extractive, dissolved in water. As lemons cannot always be obtained, the juice is often kept in a separate state; but from its liability to spontaneous decomposition, it speedily becomes unfit for medical use; and though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavour unaltered. The best medicinal substitute for lemon-juice, when the fresh fruit is not attainable, is a solution of crystallized citric acid in water, in the proportion of about an ounce to the pint, with the addition of a little oil of lemons.* One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression till a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It may also be preserved by concentrating it either by means of evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the watery portion, and leaves the acid much stronger than before. When wanted for use it may be diluted to the former strength; but though the acid properties are retained, the flavour of the juice is found to have been deteriorated.

Medical Properties and Uses. The rind of the lemon is sometimes used to qualify the taste and increase the power of stomachic infusions and tinctures. The juice is refrigerant, and properly diluted forms a refreshing and very agreeable beverage in febrile and inflammatory affections. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as gum-water, barley-water, &c., which are usually administered in fevers. It is also much employed in the formation of those diaphoretic preparations known generally by the names of *neutral mixture*, and *effervescing draught*—the former made by saturating the juice with carbonate of potassa, and given in the dose of half a fluidounce diluted with an equal quantity of water every hour, two, or three hours; the latter consisting of the same ingredients administered in the state of effervescence. No preparation with which we are acquainted is equally effectual with the *effervescing draught*, in allaying irritability of stomach and producing diaphoresis in our remittent fevers. The most convenient mode of exhibition, is to add to a fluidounce of a mixture consisting of equal parts of lemon-juice and water, half a fluidounce of a solution of carbonate of potassa, containing fifteen grains of the salt. Should effervescence not occur, as sometimes happens in consequence of the weakness of the lemon-juice, more of this should be added; as, unless sufficient acid is present to neutralize the potassa, part of the carbonate passes into the state of bicarbonate, and the gas is thus prevented from escaping. One of the most beneficial applications of lemon-juice is to the prevention and cure of scurvy, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the concentrated juice, or of crystallized citric acid with the oil of lemons. Lemon-juice is sometimes prescribed in connexion with opium and Peruvian bark, the effects of which it is thought in some instances to modify favourably, by substituting the citrate of their respective alkalies for the native salts.

LINUM. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Lineæ.

Gen. Ch. Calyx five-leaved. *Petals* five. *Capsule* five-valved, ten-celled. *Seeds* solitary. *Willd.*

Linum usitatissimum. Willd. *Sp. Plant.* i. 1533; Woodv. *Med. Bot.* p. 566. t. 202. Common flax is an annual plant with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green colour, sessile, and scattered alternately over the stem and branches. The flowers are terminal and of a delicate blue colour. The calyx is persistent, and composed of five ovate, sharp-pointed, three nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scolloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base; and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells.

This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of central Asia. It flowers in June and July, and ripens its seeds in August. Both the seeds, and an oil expressed from them, are officinal.

The seeds are oval, oblong, flattened on the sides with acute edges, somewhat pointed at one end, about a line in length, smooth, glossy, of a brown colour externally, and yellowish-white within. They are without smell, and have an oily mucilaginous taste. Their cuticle abounds in a peculiar gummy matter, which is readily imparted to hot water, forming a thick viscid mucilaginous fluid, bearing some resemblance to the solution of gum Arabic, but differing from it in several respects. It ranks among the mucilages of Berzelius. By this chemist the term *mucilage* is applied to a proximate vegetable principle, distinguished from gum by being insoluble in cold, and but slightly soluble in boiling water, in which it swells up and forms a mucilaginous, viscid body, which loses its water when placed upon filtering paper, or other porous substance, and contracts like starch in the gelatinous state. The name, however, is unfortunate, as it is generally applied to the solution of gum, and must inevitably lead to confusion. This principle is found in tragacanth, Bassora gum, cherry gum, quince seeds, and various other vegetable products. The mucilaginous fluid formed by treating it with a large proportion of cold water, is not considered by Berzelius as a proper solution, but as constituting an intermediate state between solution and mere swelling up (gonflement); for if a small proportion of water be used, a viscid mass is formed, which imparts to blotting paper on which it may be placed, a liquid in no degree mucilaginous. The mucilage of flaxseed lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with the acetate and subacetate of lead. Like gum it yields much mucic (saclactic) acid, when treated with nitric acid. By destructive distillation it affords considerable ammonia, and therefore contains nitrogen. Vauquelin found among its constituents free acetic acid, silica, and various salts of potassa and lime.

According to Guérin, the mucilage of flaxseed, obtained at a temperature of from 120° to 140°, and evaporated to dryness by means of a salt bath, contains, in 100 parts, 52.70 of a principle soluble in cold water, 29.89 of a principle insoluble in that liquid, and 10.30 of water, and yields 7.11 per cent. of ashes. The soluble part he believes to be arabin or pure gum; the insoluble he found not to afford mucic acid with the nitric, and therefore to differ from both bassorin and cerasin. There was also a small proportion of azotized matter which he did not succeed in isolating. (*An. de Chim. et Phys.* xlix. 263.)

The interior or parenchymatous part of the seeds is rich in a peculiar oil, which is separated by expression, and very extensively employed in the arts. (See *Oleum Lini.*) The ground seeds are kept in the shops under the name of *flaxseed meal.* This is of a dark gray colour, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, which is much employed for luting by practical chemists. The cake which remains after the expression of the oil still retains the mucilaginous matter of the envelope, and affords a highly nutritious food for cattle.

Medical Properties and Uses. Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in catarrh, dysentery, nephritic and calculous complaints, strangury, and other inflammatory affections of the mucous membrane of the lungs, intestines, and urinary passages. By decoction water extracts also a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

LINUM CATHARTICUM. *Lond.*

Purging Flax.

Lin cathartique, *Fr.;* Purgirflachs, *Germ.;* Lino purgativo, *Ital.*

LINUM. See LINUM.

Linum catharticum. Willd. *Sp. Plant.* i. 1541; Smith, *Flor. Brit.* 344.

This species of flax is a very small annual plant, having erect, slender stems, dichotomous near the summit, furnished with opposite, obovate, lanceolate, entire leaves, and bearing minute white flowers, the petals of which are obovate and acute. It is a native of Europe, and not found within the United States, where it is never employed as a medicine.

The herbaceous part is bitter and somewhat acrid, and imparts its virtues to water, which acquires a yellow colour. It formerly enjoyed some reputation in Europe as a gentle cathartic, but has fallen into disuse, and might very properly be expunged altogether from the officinal catalogues.

W.

LIRIODENDRON. *U.S. Secondary.*

Tulip-tree Bark.

"Liriodendron tulipifera. Cortex. *The bark.*" *U.S.*

LIRIODENDRON. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Magnoliaceæ.

Gen. Ch. Calyx three-leaved. *Petals* six. *Samaræ* sublanceolate, one or two-seeded, imbricated in a cone. *Nuttall.*

Liriodendron tulipifera. Willd. *Sp. Plant.* ii. 1254; Bigelow, *Am. Med. Bot.* ii. 107; Barton, *Med. Bot.* i. 92. This noble tree is both from its magnitude and beauty the pride and boast of American landscape. Rising on an erect, straight, cylindrical stem, which is often of nearly equal thickness for the distance of forty feet, it attains, in favourable situations, an elevation seldom less than fifty and sometimes more than one hundred feet, with a diameter of trunk varying from eighteen inches to three feet; and individuals are occasionally met with which greatly exceed these dimensions. The branches, though not very numerous, are thrown out in a somewhat regular order, and give the tree a symmetrical aspect. The bark of the stem and branches is smooth in the young trees, but in those of older growth is indented with longitudinal cracks or furrows of a depth proportioned to the age. It is of a brown or grayish-brown colour, except in the young branches, on which it is bluish or of a reddish tinge. The leaves, which stand on long footstalks, are alternate, somewhat fleshy, smooth, of a beautiful shining green colour, and divided into three lobes, of which the upper one is truncated and horizontally notched at its summit, so as to present a two-lobed appearance, and the two lower are rounded at the base and usually pointed. In the larger leaves, the lateral lobes have each a tooth-like projection at some distance below their apex. This peculiar form of the leaf serves to distinguish the tree from all others inhabiting the American forests. On isolated trees the flowers are very numerous. They are large, beautifully variegated with different colours, among which the yellow predominates, and in their general appearance bear no inconsiderable resemblance to the tulip, which has given a name to the species. Each flower stands on a distinct terminal peduncle. The calyx is double, the outer being two-leaved and deciduous, the inner consisting of three large, oval, concave leaves, of a pale green colour. The corolla is composed of six, seven, or more, obtuse, concave petals. The stamens are numerous, with short filaments, and long linear anthers. The pistils are collected into the form of a cone, the upper part of which is covered with minute stigmas. The fruit consists of numerous long, narrow scales, attached to a common axis, imbricated in a conical form, and containing each two seeds, one or both of which are often abortive.

The tulip-tree extends from New England to the borders of Florida, but is most abundant and attains the greatest magnitude in the Middle and Western States. It delights in a rich strong soil, and luxuriates in the exhaustless fertility of the banks of the Ohio and its tributary streams. Throughout the United States it is known by the inappropriate name of *poplar*, for which that of *tulip-tree* is beginning to be substituted. When in full bloom, about the middle of May, it presents in its profusion of flowers, its rich, shining, luxuriant foliage, its elevated stature, and elegant outline, one of the most magnificent objects which the vegetable kingdom affords. The interior or heart wood, which is yellowish, of a fine grain, and compact without being heavy, is much employed in the making of furniture, carriages, door-pannels, and for other useful purposes. It is recommended by its property of resisting the influence of atmospheric moisture, and the attacks of worms. The bark is the officinal portion. It is taken for use indiscriminately from the root, trunk, and branches, though that derived from the root is thought to be most active.

It is brought to the druggists in pieces of various sizes, usually five or six inches long by one or two in breadth, partially deprived of epidermis, of a yellowish-white colour, very light, and easily broken. The bark of the root is of a somewhat darker colour than that of the stem or branches. It has a feeble, but heavy and rather disagreeable odour, which is stronger in the fresh bark. The taste is bitter, pungent, and aromatic. These properties are weakened by age, and we have found specimens of the bark which have been long kept in the shops, almost insipid. The peculiar properties of liriodendron appear to reside in a volatile principle, which partially escapes during decoction. This principle has been isolated by Professor Emmet of the University of Virginia, from whom it has received the name of *liriodendrin.* In the pure state it is solid, white, crystallizable, brittle, insoluble in water, soluble in alcohol and ether, fusible at 180°, volatilizable and partly decomposed at 270°, of a slightly aromatic odour, and a bitter warm pungent taste. It appears, like camphor, to hold a place between the resins and essential oils. It is incapable of uniting with alkalies, which precipitate it from the infusion or decoction of the bark, by combining with the matter which renders it soluble in the water. Neither does it unite with acids. Water precipitates it from its alcoholic solution. It is obtained by macerating the root in alcohol, boiling the tincture with magnesia till it assumes an olive-green colour, then filtering, concentrating by distillation till the liquid becomes turbid, and finally precipitating the liriodendrin by the addition of cold water. (*Journ. of the Phil. Col. of Pharm.* iii. 5.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Medical Properties. Liriodendron is a stimulant tonic with diaphoretic properties. It has been used as a substitute for Peruvian bark in intermittent fevers, and has proved serviceable in chronic rheumatism, dyspepsia, and other complaints, in which a gently stimulant and tonic impression is desirable. The dose of the bark in powder is from half a drachm to two drachms. The infusion and decoction are also used, but are less efficient. They may be prepared in the proportion of an ounce of the bark to a pint of water, and given in the quantity of one or two fluidounces. The dose of the saturated tincture is a fluidrachm. W.

LITMUS. *Dub.*

Litmus.

"Roccella tinctoria." *Dub.*

Turnsol, Orchill; Tournesol, *Fr.;* Lakmus, *Germ.;* Oricello, *Ital.;* Orchilla, *Span.*

Various species of lichens afford, when macerated with alkaline liquors, a purple colouring matter much esteemed in dyeing. That most used at present is the *cudbear,* prepared from the *Lichen tartareus* which grows on limestone rocks in the North of Europe. The *orchill* or *litmus* is a similar dye-stuff, prepared from the *Roccella tinctoria* of Acharius, a lichen which grows on maritime rocks, and is especially abundant in the Canary and Cape Verd Islands.

Litmus is prepared by coarsely powdering the lichen, and macerating and fermenting it in close wooden vessels, for several weeks, with urine and either potash or soda. The colouring matter is thus evolved, and the prepared mass is taken out, dried, and cut into small squares for use.

Litmus as thus prepared, is in friable, violet-coloured, finely granular pieces, from a quarter of an inch to an inch in diameter, scattered over with white saline points. It has an alkaline smell, tinges the saliva of a deep blue, and is somewhat pungent and saline to the taste. It is much used as one of the most delicate tests of uncombined acids, which change its blue colour to red; and of alkalies, which restore the original hue. The most convenient mode of preparing litmus for use as a test, is to stain paper with it. For this purpose the watery infusion made with one part of powdered litmus and four of water, is applied by means of a brush to white unsized paper. The sheets when dried must be kept in close vessels in the dark.

D. B. S.

LOBELIA. *U. S.*

Indian Tobacco.

"Lobelia inflata. Herba. *The herb.*" *U. S.*

Lobelia. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Lobeliaceæ.

Gen. Ch. *Calyx* five-cleft. *Corolla* irregular, five-parted, cleft on the upper side nearly to the base. *Anthers* united into a tube. *Stigma* two lobed. *Capsule* inferior or semi-superior, two or three-celled, two-valved at the apex. *Torrey.*

Lobelia inflata. Willd. *Sp. Plant.* i. 946; Bigelow, *Am. Med. Bot.* i. 177; Barton, *Med. Bot.* i. 181. The Indian tobacco is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, sessile, oval, acute, serrate, and hairy. The flowers are numerous, disposed in leafy terminal racemes, and supported on short axillary footstalks. The segments of the calyx are linear and pointed. The corolla, which is of a delicate blue colour, has a labiate border, with the upper lip divided into two, the lower into three acute segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, brown seeds.

This species of Lobelia is a very common weed, growing on the roadsides, and in neglected fields, throughout the United States. Its flowers begin to appear towards the end of July, and continue to expand in succession till the occurrence of frost. The plant when wounded or broken exudes a milky juice. All parts of it are possessed of medicinal activity; but, according to Dr. Eberle, the root and inflated capsules are most powerful. The plant should be collected in August or September, when the capsules are numerous, and should be carefully dried. It may be kept whole, or in the state of powder.

Dried lobelia has a slight irritating odour, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended, in like manner, with a flow of saliva and a nauseating effect upon the stomach. The powder is of a greenish colour. The plant yields its active properties readily to water and alcohol; and water distilled from it retains its acrid taste. It has not been accurately analyzed.

Medical Properties and Uses. Lobelia is emetic, and like other medicines of the same class is occasionally cathartic, and in small doses diaphoretic and expectorant. It is also possessed of narcotic properties. The leaves or capsules, chewed for a short time, occasion giddiness, headach, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. Its effects in doses too large or too frequently repeated, are extreme prostration, great anxiety and distress, and ultimately death preceded by convulsions. Fatal results have been experienced from its empyrical use. These are more apt to occur when the poison, as sometimes happens, is not rejected by vomiting. In its operation upon the system, therefore, as well as in its sensible properties, lobelia bears a close resemblance to tobacco. It is among the medicines which were employed by the aborigines of this country; and was long in the hands of empyrics before it was introduced into regular practice. The Rev. Dr. Cutler of Massachusetts first attracted to it the attention of the profession.

As an emetic it is too powerful, and too distressing as well as hazardous in its operation for ordinary use. The disease in which it has proved most useful is spasmodic asthma, the paroxysms of which it often greatly mitigates, and sometimes wholly relieves, even when not given in doses sufficiently large to produce active vomiting. It was from the relief obtained from an attack of this complaint in his own person, that Dr. Cutler was induced to recommend the medicine. It has also been used in catarrh, croup, pertussis, and other pectoral affections, but generally with no better effect than may be obtained from less unpleasant and safer remedies. Administered by injection it produces the same distressing sickness of stomach, profuse perspiration, and universal relaxation as result from a similar use of tobacco. Dr. Eberle administered a strong decoction of it successfully by the rectum, as a substitute for this narcotic in a case of strangulated hernia.

It may be given in substance, tincture, or infusion. The dose of the powder as an emetic is from five to twenty grains, to be repeated if necessary. The tincture is most frequently administered. The full dose of this preparation for an adult is half a fluidounce, though in asthmatic cases it is better administered in the quantity of one or two fluidrachms, repeated every two or three hours till its effects are experienced.

Two other species of Lobelia have attracted some attention from medical writers. The *L. cardinalis*, or *cardinal flower*, distinguished for its showy red flowers, is supposed to possess anthelmintic properties; but is seldom or never used. The *L. syphilitica* is said to have been used by the Indians in the cure of the venereal disease, but has upon trial been found wholly inefficacious in that complaint. It is emetic and cathartic, and appears also to possess diuretic properties, whence it has been conjectured that it might have proved serviceable in gonorrhœa. Dr. Chapman states that it has been employed, as he has been informed, by some practitioners of the western country in dropsy, and not without success. The root is the part used. Both these species of Lobelia are indigenous. For a more detailed account of them the reader is referred to Dr. W. P. C. Barton's Medical Botany.

LUPULINA. *U.S.*

Lupulin.

"Humulus lupulus. Strobilorum pollen. *The powder attached to the strobiles.*" *U.S.*

See HUMULUS.

LYCOPUS. *U.S. Secondary.*

Bugle-weed.

"Lycopus Virginicus. Herba. *The Herb.*" *U.S.*

Lycopus. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Labiatæ.

Gen. Ch. Calyx tubular, five-cleft or five-toothed. *Corolla* tubular, four-lobed, nearly equal; the upper segment broader, and emarginate. *Stamens* distant. *Seeds* four, naked, retuse. *Nuttall.*

Lycopus Virginicus. Michaux, *Flor. Boreal. Americ.*, i. 14; Rafinesque, *Med. Flor.* vol. ii. The *bugle-weed* is an indigenous herb, with a perennial creeping root, which sends up an erect, nearly simple, obtusely quadrangular stem, from twelve to eighteen inches high, and furnished with opposite, sessile leaves. These are broad lanceolate, attenuated and entire at both extremities, remotely serrate in the middle, somewhat rough, purplish and beset with glandular dots on their under surface. The flowers are minute, in small axillary whorls, with two small subulate bractes to each flower, and a white corolla. The seeds are longer than the calyx, which is spineless.

This plant grows in shady and wet places throughout the greater part of the United States. Its flowering period is August. The whole herb is used. It has a peculiar odour, and a nauseous slightly bitter taste, and imparts these properties, as well as its medical virtues, to boiling water.

The *L. Europæus* is said to be frequently collected and sold for the *L. Virginicus.* The former may be distinguished by its acutely quadrangular stem, its narrow-lanceolate leaves of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines.

Medical Properties and Uses. According to Dr. A. W. Ives, the bugle-weed is a very mild narcotic. It was introduced into notice by Drs. Pendleton and Rogers, of New York, who obtained favourable effects from its use in incipient phthisis and hemorrhage from the lungs. (*N. Y. Med. and Phys. Journ.* i. 179.) In these complaints it is useful by diminishing the frequency of the pulse, quieting irritation, and allaying cough. It is most conveniently taken in the form of infusion, which may be prepared by macerating an ounce of the herb in a pint of boiling water, and drank ad libitum. W.

LYTHRUM SALICARIA. Herba. *Dub.*

Loosestrife. Purple Willow-herb.

Salicaire, *Fr.;* Rother Weiderich, *Germ.;* Salicaria, *Ital.*

Lythrum. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Salicareæ.

Gen. Ch. Calyx twelve toothed. *Petals* six, inserted into the calyx. *Capsule* two-celled, many-seeded. *Willd.*

Lythrum Salicaria. Willd. *Sp. Plant.* ii. 865. Loosestrife is an elegant perennial plant, two or three feet high, with an erect, quadrangular or hexagonal, downy, herbaceous stem, bearing opposite, ternate, sessile, lanceolate leaves, cordate at the base, and downy on the under surface and at the margin. The flowers are axillary, forming a leafy verticillate spike. The calyx is red, with unequal segments, the petals purple and undulate, the fruit a small elliptical capsule.

The plant grows wild in all parts of Europe, and is found in New England and Canada. It prefers meadows, swamps, and the banks of streams, which it adorns in July and August, with its showy purple flowers. The whole herbaceous part is medicinal, and is dried for use.

In this state it is inodorous, and has an herbaceous somewhat astringent taste. It renders boiling water very mucilaginous, and its decoction is blackened by the sulphate of iron.

Medical Properties and Uses. Loosestrife is demulcent and astringent; and may be advantageously given in diarrhœa and chronic dysentery after due preparation by evacuating treatment. It has long been used in Ireland in these complaints, and is said to be a popular remedy in Sweden. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root prepared by boiling an ounce in a pint of water may be given in the dose of two fluidounces. W.

◆

MAGNESIÆ CARBONAS. *U.S., Dub.*

Carbonate of Magnesia.

Off. Syn. MAGNESIÆ SUBCARBONAS. *Lond.;* CARBONAS MAGNESIÆ. *Ed.*

Carbonate de magnesie, *Fr.;* Kohlensaure Magnesia, *Germ.;* Carbonato di magnesia, *Ital.;* Carbonato de magnesia, *Span.*

Carbonate of magnesia sometimes though rarely occurs as a native mineral. That which is sold in the shops is prepared on a large scale by the manufacturer, and the article is therefore very properly placed in the list of Materia Medica of the United States Pharmacopœia. The British Colleges still retain it among the preparations, and direct it to be prepared by decomposing the sulphate of magnesia with carbonate of potassa. The Edinburgh and London Colleges use nine parts of the carbonate to twelve of the sulphate; and the Dublin College, seven parts to twelve. The *Edinburgh* process is as follows. The salts are separately dissolved in twice their weight of water, the clear solutions mixed, and eight times their weight of boiling water instantly added. The liquor is boiled a short time, with constant agitation, and the precipitated carbonate well washed and dried. The *London College* dissolves a pound of the sulphate in five pints of water, and nine ounces of the carbonate in three pints; two gallons of water are then added to the solution of the sulphate, the mixture is boiled, and the solution of the carbonate gradually added during the ebullition, the liquid being constantly stirred. The precipitate is repeatedly washed with boiling water, and dried with a heat of 200°. The *Dublin College* dissolves twenty-four parts of sulphate and fourteen parts of carbonate, each in two hundred parts of water, mixes the solutions, boils, filters, and washes the precipitate well with boiling water.

Although carbonate of potassa is thus ordered by all the Colleges, it is not as advantageously used as the carbonate of soda for the preparation of carbonate of magnesia. It is difficult to separate the last portions of sulphate of potassa from the precipitate, and the carbonate of potassa usually contains silica, which is thrown down with the magnesia. The consequence is, that when prepared by the officinal directions, the carbonate of magnesia is liable to be gritty to the touch and to have a saline taste. The following is said to be the method pursued by some of the best manufacturers. To a saturated solution of one hundred parts of sulphate of magnesia, a solution of one hundred and twenty-five parts of crystallized carbonate of soda is gradually added, the solutions being constantly stirred. The mixture is then heated to ebullition, to complete the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with the barytic salts. When it is sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it the square and compact form into which it is usually wrought.

The density of carbonate of magnesia is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch, upon the use of carbonate of soda in its preparation.

The principal part of the carbonate of magnesia used in this country is imported from Scotland. In the New England States it is prepared from the bittern of the salt works, which consists chiefly of sulphate and muriate of magnesia; and it is manufactured in Baltimore from the sulphate of magnesia prepared in that city. The Scotch magnesia is generally put up in cases of one hundred and twenty pounds each, the American in boxes containing fifty pounds.

We have spoken of the impurities which carbonate of magnesia prepared by the officinal process is apt to contain. When made from the bittern of the salt works, it is contaminated with carbonate of lime, salts of that earth being contained in sea-water; and when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided, is to prepare pure sulphate of magnesia by repeated crystallization, and to use a pure carbonate of soda. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia.

Berzelius takes the following view of the composition of this salt. When a current of carbonic acid is passed through water in which carbonate of magnesia is suspended, it is converted into a soluble bicarbonate. This salt cannot be obtained in a solid form; for if the solution is evaporated, one equivalent of the acid escapes with the water, and the carbonate crystallizes in small hexagonal prisms with plain summits. These crystals contain one equivalent of acid, one of base, and three of water. Cold water decomposes them, forming a soluble bicarbonate and an insoluble salt, containing less acid. Boiling water also decomposes them, and reduces them wholly to the state of the subsalt. The precipitate thus formed is the *magnesia alba* of the shops. It is a combination of three equivalents of carbonate of magnesia with one of hydrate of magnesia. These each contain an equivalent of water, and the composition of the salt may be thus stated;—three equivalents of carbonate (acid 66.36, magnesia 62.1, water 27,) = 155.46 + one equivalent of hydrate (magnesia 20.7, water 9,) = 29.7 = 185.16. This theoretic composition agrees very nearly with the analysis of Berzelius, who fixes it at 44.75 magnesia, 35.77 acid, and 19.48 water.

The composition of this salt varies with the mode of preparation. Thus Bucholz by decomposing the sulphate of magnesia with 170 per cent. of carbonate of soda, and using only cold water throughout, obtained a very light, spongy, somewhat coherent magnesia, containing 32 acid, 33 base, and 35 water. By using 120 per cent. of the carbonate, and boiling the water for fifteen minutes, he obtained a heavy granular precipitate containing 35 acid, 42 base, and 23 water.

Carbonate of magnesia is inodorous, nearly insipid, perfectly white, very light, smooth to the touch, and nearly insoluble in water, requiring 2493 parts of cold, and 9000 parts of hot water for solution. (*Turner's Chemistry.*) It is decomposed by a strong heat, by all the acids, by potassa, soda, lime, baryta, and strontia, by the sulphate, phosphate, nitrate, and muriate of alumina, and by acidulous and metallic salts.

A solution in carbonic acid water, prepared by passing carbonic acid gas into a reservoir containing the carbonate of magnesia suspended in water, has been introduced into use as a cathartic and antacid; but is in no respect preferable to the undissolved carbonate, while it is more unpleasant to the taste.

Medical Properties and Uses. The carbonate of magnesia is antacid, and by combining with acid in the stomach, becomes gently cathartic. When it undergoes no change in the alimentary canal, it produces no purgative effect. Under these circumstances, it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid; and though apt to produce flatulence in consequence of the extrication of its carbonic acid in the stomach and bowels, and therefore in ordinary cases inferior to the calcined magnesia, it sometimes operates favourably, in consequence of this very property, in sick stomach attended with acidity. The carbonate of magnesia is also an excellent antilithic in those cases in which uric acid is secreted in too great abundance.

The dose is from half a drachm to two drachms, which may be given suspended in water or milk. In order that it may be accurately diffused through water, it should be previously rubbed down with simple syrup or ginger syrup.*

MAGNESIÆ SULPHAS. *U.S., Lond., Dub.*

Sulphate of Magnesia.

Off. Syn. SULPHAS MAGNESIÆ. *Ed.*

Epsom salt; Sulfate de magnésie, *Fr.;* Schwefelsaure Magnesia, *Germ.;* Solfato di magnesia, *Ital.;* Sulfato de magnesia, *Span.*

Sulphate of magnesia is one of the constituents of sea-water, and of some saline springs. It also occurs native, either crystallized in long, slender, prismatic, adhering crystals, or as an efflorescence on certain rocks and soils, which contain magnesia and a sulphate or sulphuret. In the United States it is found abundantly in the great caverns, so numerous to the west of the Alleghany mountains. In one of these caves, near Corydon in Indiana, it forms a stratum on the bottom several inches deep; or appears in masses sometimes weighing ten pounds; or is disseminated in the earth of the cavern, one bushel of which yields from four to twenty-five pounds of this sulphate. It also appears on the walls of the cavern, and if it be removed, acicular crystals again appear in a few weeks. (*Cleaveland.*)

The sulphate of magnesia was originally procured by evaporating the waters of some saline springs at Epsom in England. Dr. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine remaining after the crystallization of common salt from sea-water, furnished by careful evaporation precisely the same salt; and as this was a much cheaper product it superseded the former. This residual brine or bittern consists of sulphate of magnesia and the muriates of magnesia and lime. As the sulphate of magnesia crystallizes first, it may with proper care be obtained nearly pure, although most frequently the salt prepared in this way is deliquescent, from being contaminated with the muriate of magnesia. It may be purified from this mixture by washing the crystals with its own saturated solution. It was from this source that the greater part of the Epsom salt of commerce was long obtained in Europe. The salt works of New England supplied our own markets with an impure and deliquescent sulphate. With the improvements in chemistry, other and better processes have latterly been adopted. In the neighbourhood of Genoa and of Nice, in Italy, sulphate of magnesia is prepared in large quantities from a schistose rock, which contains magnesia and sulphuret of iron. The mineral is roasted and exposed in heaps for some months to the combined action of air and water. It is then lixiviated, the sulphate of iron decomposed by lime-water, and the salt is obtained pure by repeated solution and crystallization.

William Henry of Manchester, whose calcined magnesia has become famous throughout the world, took out a patent for a mode of preparing magnesia and its salts from the double carbonate of magnesia and lime—the dolomite of mineralogists. His process was to drive off the carbonic acid by heat, and to convert the remaining earths into hydrates. He treated these with a sufficient quantity of muriatic acid to dissolve out the lime, and then converted the magnesia into a sulphate either by sulphuric acid or sulphate of iron.

Within a few years this salt has been extensively manufactured at Baltimore from the siliceous hydrate of magnesia, or magnesite. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighbourhood of that city, and in the southern counties of Pennsylvania. The advantage which it possesses over the dolomite, in the preparation of this salt, is the almost entire absence of lime, owing to which circumstance there is little or no waste of acid and the operation is much simplified. The mineral is reduced to a fine powder, and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert the sulphate of iron which may be present into red oxide. It is then dissolved in water, and sulphuret of lime added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared at the Baltimore works by this process is generally very pure and clean, although it sometimes contains sulphate of iron.

Sulphate of magnesia is a colourless transparent salt, without smell, and of a bitter, nauseous, saline taste. It crystallizes in quadrangular prisms, terminating in a four-sided pyramid or in a dihedral summit. It usually occurs in small acicular crystals. It slowly effloresces in the air. At 32° of Fahrenheit, 100 parts of water dissolve 25.76 parts of the anhydrous salt, and for every increased degree of heat 0.8597 parts additional are taken up. The crystals contain 51.22 per cent. of water of crystallization, and dissolve in their own weight of water at 60°, and in three-fourths of their weight of boiling water; they melt in their water of crystallization, and at a high temperature fuse into an enamel. (*Berzelius.*) This salt consists of one equivalent of acid = 40.1, one of base = 20.7, and seven of water = 63; and its combining number is 123.8.

Sulphate of magnesia is completely decomposed by potassa, soda, and their carbonates; by lime, baryta, and strontia, and their soluble salts. Ammonia partially decomposes it, and forms with the remaining salt a double sulphate. The bicarbonates of potassa and soda do not decompose the sulphate of magnesia, except by the aid of heat.

Sulphate of magnesia is liable to contain iron and muriate of magnesia, the former of which may be detected by ferrocyanate of potassa, and the latter by its occasioning the salt to deliquesce. Sulphate of soda, made to crystallize in small needle-shaped crystals by constant stirring while it is cooling, was formerly substituted for this salt; but the fraud is no longer profitable, on account of the cheapness of the magnesian sulphate. The Baltimore works supply the whole United States with sulphate of magnesia.

Medical Properties and Uses. Sulphate of magnesia is a mild and safe cathartic, operating with little pain or nausea, and producing watery stools. It is more acceptable to the stomach than most medicines of its class, and will often be retained when others are rejected. Like many of the other neutral salts it is refrigerant, and may be made to act as a diuretic, by keeping the skin cool and walking about after it has been taken. It is well adapted to the treatment of fevers and inflammatory affections, especially after a previous thorough evacuation of the bowels by a more energetic cathartic. It is also useful in colic and obstinate constipation, and may be employed in most cases which require the use of a cathartic, without being attended with debility or relaxation of the stomach and bowels. The medium dose is an ounce; but advantage often results from its administration in divided doses frequently repeated. It is frequently given in combination with other medicines, especially with senna, the griping effect of which it tends to obviate. The pleasantest form for administering the salt, and that in which it usually agrees best with the stomach, is a solution in carbonic acid water with lemon syrup. By Dr. Henry of Dublin it is highly recommended in connexion with sulphuric acid. To seven ounces of the saturated aqueous solution of the salt he adds an ounce of the diluted sulphuric acid of the Pharmacopœias, and gives a tablespoonful of the mixture for a dose, in a wineglassful of water.

MAGNOLIA. *U.S. Secondary.*

Magnolia.

"Magnolia glauca, Magnolia acuminata, et Magnolia tripetala. Cortex. *The bark.*" *U.S.*

Magnolia. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Magnoliaceæ.

Gen. Ch. Calyx three-leaved. *Petals* six or more. *Capsules* two-valved, one-seeded, imbricated in a cone. *Seeds* berried, pendulous. *Bigelow.*

The medicinal properties which have rendered the bark of the Magnolia officinal, are common to most, if not all of the species composing this splendid genus. Among the numerous trees which adorn the American landscape, these are most conspicuous for the beautiful richness of their foliage, and the magnificence as well as delicious odour of their flowers; and the *M. grandiflora* of the Southern States rivals in magnitude the largest inhabitants of our forests. The Pharmacopœia designates the *M. glauca*, *M. acuminata*, and *M. tripetala*, each of which we shall briefly describe.

1. *Magnolia glauca.* Willd. *Sp. Plant.* ii. 1256; Bigelow, *Am. Med. Bot.* ii. 67; Barton, *Med. Bot.* i. 77; Michaux, *N. Am. Sylv.* ii. 8. This species of Magnolia, which in the Northern States is often nothing more than a shrub, sometimes attains in the South the height of forty feet. The leaves are scattered, petiolate, oval, obtuse, entire, glabrous, thick, opaque, yellowish-green on their upper surface, and of a beautiful pale glaucous colour beneath. The flowers are large, terminal, solitary, cream-coloured, strongly and gratefully odorous, often scenting the air to a considerable distance. The calyx is composed of three leaves; the petals, from eight to fourteen in number, are obovate, obtuse, concave, and contracted at the base; the stamens are very numerous, and inserted on a conical receptacle; the germs are collected into a cone, and each is surmounted by a linear recurved style. The fruit is conical, about an inch in length, consisting of numerous imbricated cells, each containing a single scarlet seed. This escapes through a longitudinal opening in the cell, but remains for some time suspended from the cone by a slender thread to which it is attached.

The M. glauca extends along the seaboard of the United States, from Cape Ann in Massachusetts to the shores of the Gulf of Mexico. It is abundant in the Middle and Southern States, usually growing in swamps and morasses; and is seldom met with in the interior of the country west of the mountains. It begins to flower in May, June, or July, according to the latitude. It is known by the name of *magnolia* simply in the Northern and Middle States; by that of *white bay* or *sweet bay* in the South, and is occasionly called *swamp sassafras, beaver tree, &c.*

2. *M. acuminata.* Willd. *Sp. Plant.* ii. 1257; Michaux, *N. Am. Sylv.* ii. 12. This species is much larger than the preceding, often growing to the height of seventy or eighty feet. The leaves are six or seven inches long, by three or four in breadth, oval, acuminate, and pubescent on their

under surface. The flowers are five or six inches in diameter, bluish or cream-coloured, slightly odorous, with obovate rather obtuse petals from six to nine in number. Mingled with the splendid foliage, they give a magnificent aspect to the tree when large and in full bloom. The tree grows in the mountainous regions in the interior of the United States, extending along the Alleghanies from the state of New York to their termination in Georgia, and seldom existing in the low country far either to the east or the west of this range. Wherever it is found, it is called *cucumber tree*, from the resemblance of its fruit in shape and size to this product of the gardens.

3. *M. tripetala.* Willd. *Sp. Plant.* ii. 1258; Michaux, *N. Am. Sylv.* ii. 18. This is a small tree, sometimes though rarely reaching an elevation of thirty feet, and almost always having an inclined trunk. It is remarkable for the size of its leaves and flowers. The former are eighteen or twenty inches long, by seven or eight in breadth, thin, obovate, somewhat wedge-shaped, entire, acute at both extremities, pubescent when young, and often disposed in rays at the extremity of the shoots, displaying a surface thirty inches in diameter. Hence has arisen the name of *umbrella tree*, by which this species is distinguished. The flowers are terminal, seven or eight inches in diameter, white, with from five to twelve oval acute petals, of which the three outer are reflexed. This species extends from the northern parts of New York to the southern limits of the United States. It is found only in situations which are shady, with a strong, deep, and fertile soil. It is common in some of the islands of the Susquehanna, and still more so in the Southern and South Western States. *Michaux.*

The bark and fruit of all the species of Magnolia are possessed of similar medicinal properties; but the bark only is officinal; and that of the root is thought to be most efficient. It has an aromatic odour, and a bitter, pungent, spicy taste. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency.

Medical Properties and Uses. Magnolia is a gently stimulant aromatic tonic and diaphoretic, useful in chronic rheumatism, and capable, if freely given, of arresting the paroxysms of intermittent fever. It has been used advantageously in these complaints, and in remittents, especially of a typhoid character. The dose of the recently dried bark in powder is from half a drachm to a drachm, frequently repeated. The infusion may also be used, but is less efficient. Diluted alcohol extracts all the virtues of the medicine; and a tincture made by macerating the fresh bark or cones in brandy, is a popular remedy in chronic rheumatism. W.

MALVA. *Lond.*

Mallows.

"Malva sylvestris." *Lond.*

Off. Syn. MALVÆ SYLVESTRIS HERBA. MALVÆ SYLVESTRIS FLORES. *Ed.*

Mauve sauvage, *Fr.;* Waldmalve, *Germ.;* Malva, *Ital., Span.*

Malva. *Sex. Syst.* Monadelphia Polyandria.—*Nat. Ord.* Malvaceæ.

Gen. Ch. Calyx double, the exterior three-leaved. *Capsules* very many, one-seeded. *Willd.*

Malva sylvestris. Willd. *Sp. Plant.* iii. 787; Woodv. *Med. Bot.* p. 554. t. 197. This is a perennial, herbaceous plant, with a round, hairy, branching, usually erect stem, from one to three feet high, bearing alternate, petiolate, cordate, roughish leaves, which are divided into five or seven crenate lobes, and on the upper part of the stem are almost palmate. The flowers are large, purplish, and placed from three to five together at the axils of the leaves, upon long slender peduncles, which, as well as the petioles, are pubescent. The petals are five in number, inversely cordate, and three times as long as the calyx. The capsules are disposed compactly in a circular form.

This species of mallow is a native of Europe, where it grows abundantly on waste grounds and by the way-sides, flowering from May to August. It is sometimes cultivated in our gardens. Other species, indigenous or naturalized in this country, are possessed of the same properties, which are in fact common to the whole genus. The *M. rotundifolia* is one of the most common, and may be substituted for the *sylvestris* without disadvantage.

The herb and flowers, which are the officinal parts, have a weak, herbaceous, slimy taste, without any odour. They abound in mucilage, which they readily impart to water; and the solution is precipitated by acetate of lead. The infusion and tincture of the flowers are blue, and serve as an excellent test of acids and alkalies, being reddened by the former, and rendered green by the latter. The roots and seeds are also mucilaginous, but are less used.

Medical Properties and Uses. Mallows are emollient and demulcent. The infusion and decoction are sometimes employed in catarrhal, dysenteric, and nephritic complaints; and are applicable to all other cases which call for the use of mucilaginous liquids. They are also used as an emollient injection; and the fresh plant forms a good suppurative or relaxing cataplasm in external inflammation. Mallows were formerly among the culinary herbs.

W.

MANGANESII OXYDUM. *Dub.*

Oxide of Manganese.

Manganese, Black oxide of manganese; Oxide noir de manganese, *Fr.;* Braunstein, *Germ.;* Manganese, *Ital., Span.*

Of the Pharmacopœias noticed in this work, black oxide of manganese is officinal only in that of the Dublin College. It is the peroxide of a peculiar metal properly called manganese; though this name is commonly applied to the oxide under consideration. *Metallic manganese* was discovered by Scheele and Gahn in 1774, and is obtained from the native black oxide by intense ignition with charcoal. It is hard, brittle, granular, of a grayish-white colour, and emits a disagreeable odour in a moist atmosphere. It oxidizes readily by the action of the air, first tarnishing, then assuming a yellowish or violet colour, and finally becoming converted into a black powder. Its sp. gr. is 8, melting point 160° of Wedgwood, and equivalent number 27.7. With oxygen it forms five combinations, three regular oxides and two acids. The *protoxide* is of a light green colour, and is the oxide present in the salts of manganese. The *sesquioxide* is black or dark brown, and the *peroxide* black. The two acids are formed by the action of potassa on the peroxide, and are called *manganic* and *permanganic acid.* Assuming one equiv. of manganese in each of these combinations, the protoxide is found to contain one, the sesquioxide one and a half,* the peroxide two, manganic acid three, and permanganic acid three and a half equivalents of oxygen. (*Berzelius.*) Besides these, there exist a double oxide, of a brownish-red colour, called the *red oxide*, consisting of one equiv. of protoxide and one of sesquioxide, and invariably formed when any one of the other oxides of manganese is exposed to a white heat; and a native oxide, called *Varvicite*, composed of two equiv. of peroxide, and one of sesquioxide. Metallic manganese is an occasional constituent of organic matter. It was detected in minute quantity in bones by Fourcroy and Vauquelin, and is often present in the ashes of plants. In the mineral kingdom, it occurs sometimes as a sulphuret, rarely as a phosphate, but very abundantly as the black or peroxide. It is this latter mineral which constitutes the officinal oxide of the Dublin College.

Properties. Peroxide of manganese, as it occurs in nature, is very variable in its appearance. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having the metallic lustre, but far more frequently in the form of a dull earthy looking substance of a black or brown colour. When crystallized it is the purest. As it occurs in commerce it is usually in the form of powder, of a black colour, insoluble in water, and containing as impurities more or less oxide of iron, carbonate of lime, and argillaceous matter. When exposed to a red heat it yields a considerable quantity of oxygen, and is reduced to the state of sesquioxide. It is distinguished from the sulphuret of antimony by its infusibility, and by its causing the evolution of chlorine on the addition of muriatic acid. When of a brown colour, it is not of good quality. Its composition has been given above.

But few mines of peroxide of manganese exist, though the metal itself is very generally diffused throughout the mineral kingdom. It occurs most abundantly in Bohemia, Saxony, the Hartz, France, and Great Britain. In England the most abundant mine is that of Upton Pine, near Exeter, which furnishes the best oxide of manganese found in Great Britain. In the United States no mines have been opened, except in Vermont, from which state an inferior brown ferruginous manganese is supplied through Boston. Besides this source of supply, the mineral is received from Nova Scotia, France, Germany, England, and occasionally Scotland. It comes packed in casks or barrels, generally in lumps and coarse powder, just as it is dug out of the mines; though occasionally it is received from England ready pulverized. It is a good general rule to buy it unpowdered, as its quality can be better judged of in that state. A dark shining crystalline appearance may be taken as an indication of good quality. The Nova Scotia manganese is better than the Vermont; but that received from Germany and England is the best, and commands the highest price in the market. The Scotch manganese, which has only been latterly received in this country, is of good quality.

Medical Properties and Uses. The therapeutic effects of this oxide have not been regularly investigated. The only notice we have seen of its medical use is its employment in the form of ointment, in the proportion of one or two drachms to the ounce of lard, for the cure of porrigo, in which disease it is said to succeed well.

Peroxide of manganese is used in the arts for obtaining chlorine for the purpose of bleaching, to give a black glazing to pottery, and for freeing glass from the colour which it derives from the peroxide of iron. According to Berzelius, a few pounds of it added to each cask of water intended for sea-voyages, will preserve it sweet. In the laboratory, it is employed to obtain oxygen and chlorine, and to form the salts of manganese. The only use made of it by the Dublin College is to procure the aqueous solution of chlorine. (See *Aqua Chlorinii.*) B.

---

* In order to avoid fractional equivalents, the sesquioxide is supposed to consist of two equiv. of metal, and three of oxygen, which is the same proportion and given in the text.

MANNA. *U.S., Lond., Ed., Dub.*

Manna.

"Fraxinus ornus. Succus concretus. *The concrete juice.*" *U. S.*

Manne, *Fr.;* Manna, *Germ., Ital.;* Mana, *Span.*

Manna is not the product of one plant exclusively. Besides the *Fraxinus Ornus* indicated by the Pharmacopœias, it is afforded by several other species of the same genus, among which the *F. rotundifolia*, *F. excelsior*, and *F. parviflora* are particularly mentioned. Burkhardt states that a species of manna, which exudes from the tamarisk of the North of Africa, is used by the Bedouin Arabs of the neighbourhood of Mount Sanai with their food. It is, however, chemically different from common manna, as, according to M. Mitscherlich, it contains no mannite, but consists wholly of mucilaginous sugar. Dr. Ehrenbergh found the tree which produces it to be a variety of the Tamarix Gallica. The manna used in India is said to be the product of the *Hedysarum Alhagi* of Linn., the *Alhagi Maurorum* of De Candolle, a thorny shrub, which grows abundantly in the deserts of Persia and Arabia. It is, however, much inferior to that obtained from the different species of ash. We are told by Dr. Richardson, that a substance exactly resembling manna, is procured by exudation from a species of *Eucalyptus* called the *E. manifera*, growing in New South Wales. The substance known, in France, by the name of *Briançon Manna*, is an exudation upon the surface of the common European larch—*Pinus Larix* or *Larix Europæa*—and differs chemically from the product of the Fraxinus, in containing no mannite.

Fraxinus. *Sex. Syst.* Polygamia Diœcia.—*Nat. Ord.* Jasmineæ, *Juss.;* Oleaceæ, *Lindley.*

Gen. Ch. Hermaphrodite. *Calyx* none, or four-parted. *Corolla* none, or four-petaled. *Stamens* two. *Pistil* one. *Samarra* one-seeded, terminated by a lanceolate wing. Female. *Calyx* none, or four-parted. *Corolla* none, or four-petaled. *Pistil* one. *Samarra* one-seeded, terminated by a lanceolate wing. *Willd.*

Fraxinus Ornus. Willd. *Sp. Plant.* iv. 1104; Woodv. *Med. Bot.* p. 589. t. 209. The *flowering ash* is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiolate, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the extremity. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright green colour, and stand on short footstalks. The flowers are white, and usually expand at the same time with the leaves. They grow in close panicles at the extremity of the young branches, and have a very short calyx with four teeth, and a corolla composed of four linear lanceolate petals.

Both this species of Fraxinus, and the *F. rotundifolia*, are natives of Sicily, Calabria, and Apulia; and both contribute to supply the manna of commerce. During the hot months, the juice exudes spontaneously from the bark, and concretes upon its surface; but as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for thirty or forty years, during which the trees are said to yield manna. Straws or clean chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies much in its character, according to the mode of collection and nature of the season, and the period of the year in which the exudation takes place. That procured in Sicily is said to be the best. Three varieties are distinguishable in commerce.

1. The purest is that usually known by the name of *flake manna.* It exudes spontaneously or by incisions during the hottest and dryest weather in the months of July and August. It is in irregular, unequal pieces, somewhat similar in appearance to stalactites, rough, light, porous, brittle, of a whitish or yellowish-white colour, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces present a crystalline or granular structure.

2. *Common manna—manne en sorte* of French Pharmacy—is next in quality, and is collected in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. The common manna consists of whitish or yellowish fragments similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized, brownish mass, identical with that which constitutes the following variety.

3. *Fat manna* is collected in the latter part of October and November, when the weather is cooler and rains more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce it is in the form of a soft, viscous mass, containing few crystalline fragments, of a brown or yellowish-brown colour, and full of impurities.

Manna may be found in the shops of every grade, from the most impure of the third variety to the purest of the first.

Attempts have sometimes been made to counterfeit it; but the facility of detection renders frauds of this kind unprofitable, and they are not often practised.

Properties. Manna has a slight, peculiar odour, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna, scarcely so much so as to be disagreeable. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold, and in its own weight of boiling water. From a boiling saturated aqueous solution, it separates in partially crystalline masses. Alcohol also dissolves it, and if saturated by means of heat, deposites upon cooling a large proportion of the manna in a beautifully crystalline form. Analyzed by Fourcroy and Vauquelin, manna was found to consist of, 1. a peculiar crystallizable saccharine principle, called *mannite,* which constitutes seventy-five per cent.; 2. true sugar; 3. a yellow nauseous matter, upon which the purgative property chiefly depends; and 4. a small quantity of mucilage. It is owing to the presence of true sugar that manna is capable of fermenting. *Mannite* is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and precipitated when it cools. Unlike sugar, it is incapable of undergoing the vinous fermentation. It may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate. It is the pure mannite which is now thrown down. This principle has been found in numerous vegetables. It is said to act as a gentle laxative, in the dose of one or two ounces.

Manna, when long kept, acquires a deeper colour, softens, and ferments. That which is dryest resists this change the longest. We are told that when recently gathered it is less purgative than it afterwards becomes.

Medical Properties and Uses. Manna is a gentle laxative, usually operating pleasantly, but in some cases, producing flatulence and pain. Though peculiarly adapted to children and pregnant women, it may be given with advantage in ordinary cases of piles from constipation, unattended with dyspeptic symptoms. It is usually, however, prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect.

The dose for an adult is from one to two ounces; for children, from one to four drachms. It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be conveniently administered in substance.

MARANTA. *U.S.*

Arrow-root.

"Maranta arundinacea. Radicis fæcula. *The fecula of the root.*" *U.S.*

Arrow-root, *Fr.;* Amerikanisches Stärkmehl, Arrowmehl, *Germ.*

Maranta. *Sex. Syst.* Monandria Monogynia.—*Nat. Ord.* Cannæ, *Juss.;* Marantaceæ, *Lindley.*

Gen. Ch. *Anther* attached to the petal-like filament. *Style* petal-shaped. *Stigma* three-sided. *Flowers* panicled. *Loudon's Encyc.*

Maranta arundinacea. Willd. *Sp. Plant.* i. 13; *Loudon's Encyc. of Plants*, p. 2. The root of this plant is perennial, tuberous, fleshy, horizontal, nearly cylindrical, scaly, from six inches to a foot or more in length, and furnished with numerous long, white fibres. The stems, of which several rise from the same root, are annual, slender, branched, jointed, leafy, and about three feet in height. The leaves are ovate lanceolate, about four inches long, alternate, and supported solitarily at the joints of the stem upon long, sheathing footstalks. The flowers are in a long, loose, spreading, terminal panicle, at each ramification of which is a solitary linear bracte. The calyx consists of three small lanceolate leaves. The corolla is white and monopetalous, with a tube longer than the calyx, and a double border, of which the three outermost segments are smallest, and the two inner obovate, and slightly emarginate.

The arrow-root plant is a native of South America and of the West Indies, where it is largely cultivated. It grows also in Florida, and has been cultivated in our Southern States, but not very extensively, as we still derive our supplies of its product from abroad. The plant is easily propagated by cuttings of the root. In the West Indies, the fecula, so well known by the name of arrow-root, is prepared in the following manner. The roots are dug up when a year old, washed, and then beat into a pulp, which is thrown into water, and agitated so as to separate the amylaceous from the fibrous portion. The fibres are removed by the hand, and the starch remains suspended in the water, to which it gives a milky colour. This milky fluid is strained through coarse linen, and allowed to stand that the fecula may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun. We obtain arrow-root chiefly from the West Indies, and the ports of Brazil.

It is probable that other plants contribute to furnish the arrow-root of commerce. Lindley states that it is procured in the West Indies from the *Maranta Allouya* and *M. nobilis*, besides the *M. arundinacea*. Under the name of *M. Indica*, Tussac describes a distinct species which he says was originally brought from the East Indies, and is now cultivated in Jamaica. This species, however, is not admitted by any of the British botanists whom we have consulted. Very fine arrow-root is obtained in the East Indies from the root of the *Curcuma angustifolia* of Roxburgh, which is abundantly cultivated in Travancore. Parcels have occasionally reached this country; but from the length of the voyage are apt to be more or less musty. The East India arrow-root is lighter than ours, and does not so quickly make a jelly. Ainslie informs us that the *M. arundinacea* has lately been introduced from the West Indies into Ceylon, where good arrow-root is prepared from it. A fecula closely resembling that of the Maranta, is said by Guibourt to be prepared in the West Indies from the root of the cassava plant, *Jatropha Manihot;* and it is not improbable that a portion of the arrow-root brought to the United States has a similar origin. In fact, that imported from South America often contains small lumps, as large as a pin's head, identical with tapioca, which is a product of the *J. Manihot*. Arrow-root has recently been advertised as coming from the Sandwich Islands. It is probably identical with that said to be procured from the root of the *Tacca pinnatifida*, which grows abundantly in Tahiti and other islands of the South Pacific.

Arrow-root is in the form of a light white powder, or of small pulverulent masses, without smell or taste. It is a pure starch, identical in chemical properties with that of wheat and the potato. It is very apt to be musty, and should then be rejected. It is said to be sometimes adulterated with common starch, and with that of the potato. There is no certain mode of detecting these, unless the microscope may afford the means. (See *Amylum.*) The odour and taste are the best criteria of its purity. It should be perfectly free from smell and unpleasant flavour.

Attempts have been made to substitute finely prepared potato starch for arrow-root; and there is no doubt that, medically considered, it is quite equal; but patients complain of an unpleasant taste of the potato which it is apt to retain.

Medical Properties and Uses. Arrow-root is nutritious and demulcent, affording a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties to bowel complaints and diseases of the urinary passages. It is much used as food for infants after weaning, or when the mother's milk is insufficient. It is prepared by dissolving it in hot water, with which it forms a pearly gelatinous solution, and, if in sufficient quantity, a jelly-like mass on cooling. A table-spoonful will communicate sufficient consistence to a pint of water. It should first be formed into a paste with a small quantity of cold water, and the boiling water then gradually added with brisk agitation. The preparation may be rendered more palatable by the addition of lemon-juice and sugar, or in low forms of disease by that of wine and spices, if the latter are not contraindicated. For children the arrow-root is usually prepared with milk. W.

MARRUBIUM. *U.S. Secondary.*

Horehound.

"Marrubium vulgare. Herba. *The herb.*" *U.S.*

Off. Syn. MARRUBIUM. Marrubium vulgare. *Lond.;* MARRUBII VULGARIS HERBA. *Ed.;* MARRUBIUM VULGARE. *Dub.*

Marrube blanc, *Fr.;* Weisser Andorn, *Germ.;* Marrubio, *Ital., Spa n.*

Marrubium. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Calyx* salver-shaped, rigid, ten-streaked. *Corolla* with the upper lip bifid, linear, and straight.

Marrubium vulgare. Willd. *Sp. Plant.* iii. 111; Woodv. *Med. Bot.* p. 332. t. 118. The *white horehound* has a perennial fibrous root, and numerous annual stems, which are quadrangular, erect, very downy, and from twelve to eighteen inches high. The leaves are roundish ovate, dentate or deeply serrate, wrinkled, veined, hoary on the under surface, and supported in pairs upon strong footstalks. The flowers are white, and disposed in crowded axillary whorls. The calyx is tubular, and divided at the margin into ten narrow segments which are hooked at the end. The corolla is also tubular, with a labiate margin, of which the upper lip is bifid, the under reflected and three-cleft, with the middle segment broad and slightly scolloped. The seeds are four, and lie in the bottom of the calyx.

This plant is a native of Europe, but has been naturalized in this country, where it grows on the roadsides, and flowers in July and August. It is also cultivated in our gardens.

The herb has a strong rather agreeable odour, which is diminished by drying, and is lost by keeping. Its taste is bitter and durable. The bitterness is extracted by water and alcohol.

Medical Properties and Uses. Horehound is tonic, in large doses laxative, and may be so given as to increase the secretion from the skin, and occasionally from the kidneys. It was formerly considered a valuable deobstruent, and recommended in chronic hepatitis, jaundice, menstrual obstructions, phthisis, and various cachectic affections. By its gently tonic powers it may undoubtedly have proved advantageous in some of these complaints; but it exerts no specific influence over any; and has now passed almost entirely from the hands of physicians into domestic use. It is employed chiefly in catarrh, and other chronic affections of the lungs attended with cough and copious expectoration. The infusion made in the proportion of an ounce of the herb to a pint of boiling water, may be given in wineglassful doses. The dose of the powder is from thirty grains to a drachm. The medicine is also much used in the shape of syrup and candy.

MASTICHE. *Lond.*

Mastich.

"Pistacia Lentiscus. *Resina.*" *Lond.*

Off. Syn. PISTACIÆ LENTISCI RESINA. *Ed.;* MASTICHE. PISTACIA LENTISCUS. Resina. *Dub.*

Mastic, *Fr.;* Mastix, *Germ.;* Mastice, *Ital.;* Almastiga, *Span.;* Sakes, *Turk.;* Arab, *Arab.*

Pistacia. *Sex. Syst.* Diœcia Pentandria.—*Nat. Ord.* Terebintaceæ, *Juss.;* Anacardiaceæ, *Lindley.*

Gen. Ch. Male. *Calyx* five-cleft. *Corolla* none. Female. *Calyx* three-cleft. *Corolla* none. *Styles* three. *Drupe* one-seeded. *Willd.*

Pistacia Lentiscus. Willd. *Sp. Plant.* iv. 753; Woodv. *Med. Bot.* p. 26. t. 11. The *lentisk* is a shrub or small tree, seldom rising more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The leaflets are from eight to twelve in number, usually alternate, with the exception of the two upper which are opposite. They are ovate lanceolate, entire, obtuse, often mucronate, and sessile upon the common footstalk, which is winged, or furnished with a narrow foliaceous expansion on each side. The flowers are diœcious, and very small. The male are in an axillary ament; the female are arranged alternately upon a common peduncle, which is also axillary.

This tree is a native of the countries which border upon the Mediterranean; but does not yield mastich in all places. The island of Scio in the Grecian Archipelago is the place whence the drug is chiefly obtained. Incisions are made in the trunk and principal branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is sometimes received upon cloths spread for the purpose, sometimes upon the bare earth, and concretes in irregular masses. The tears are most highly valued.

They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale yellow colour, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. The masses are composed of yellowish tears agglutinated together, with others of a darker colour and less translucent, and often fragments of wood, bark, or earthy matter intermingled.

Mastich is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable under the teeth, but soon becomes soft and ductile, and acquires a white opaque appearance. Its sp. gr. is 1.074. It is fusible and inflammable by heat. Alcohol dissolves about four-fifths of it, leaving a viscid substance which becomes brittle when dried, and for which the name of *masticin* has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. According to Berzelius, it enjoys the same general properties as copal, and should be considered as a variety of resin. Mastich is wholly soluble in ether and in oil of turpentine, scarcely soluble in the fixed oils, and insoluble in water. It consists chiefly of resin, with *masticin*, and a minute proportion of volatile oil, which can scarcely be said to have been obtained in a separate state, though it imparts flavour to alcohol and water distilled from the mastich, especially when this has been previously triturated with an equal weight of carbonate of potassa.

Medical Properties and Uses. Mastich was formerly thought to possess properties analogous to those of the turpentines, and was used in debility of the stomach, hæmoptysis from ulceration, leucorrhœa, chronic diarrhœa, &c.; but its virtues were overrated; and it is at present scarcely ever given internally. It is sometimes employed to fill the cavities of carious teeth, for which purpose it is well fitted by its softness. Great quantities of it are consumed in Turkey, where it is habitually chewed by the women, under the impression that it sweetens the breath and preserves the gums and teeth. Dissolved in alcohol or oil of turpentine, it serves for the formation of a brilliant varnish.

The following mode of applying it to carious teeth is highly recommended. Dissolve four parts of mastich in one part of sulphuric ether, in a bottle well stopped. With the solution thus formed, which is of a yellow colour and oily consistence, saturate a small piece of cotton of the size of the carious cavity, and having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The ether is soon evaporated, and the resin, remaining soft and adhesive, attaches itself to the diseased surface of the tooth, which it protects from the action of the air, and of the food taken into the mouth. (*Journ. de Pharm.* xx. 597.) W.

MEL. *U.S., Lond., Ed., Dub.*

Honey.

Miel, *Fr.;* Honig, *Germ.;* Miele, *Ital.;* Miel, *Span.*

Naturalists have not yet determined whether honey is a secretion of the bee, *Apis mellifica*, or whether it exists already formed in plants. It is certain that the nectaries of flowers contain a saccharine matter, which is extracted by the insect; and the fact is well known that the flavour and character of honey are very much affected by the nature of the plants which predominate in the vicinity of the hive; so much so, that when these plants are poisonous, the fluid sometimes partakes of their noxious qualities. Still, it probably undergoes some change in the organs of the bee; as the saccharine matter of the nectaries, so far as it has been possible to examine it, wants some of the characteristic properties of honey.

The finest honey is that which is allowed to drain from the comb. If obtained from hives which have never swarmed, it is called *virgin honey*. An inferior kind is procured by exposing the comb to pressure, and if heat be employed previously to expression, the product is still more impure.

Much honey is collected in different parts of the United States; but that with which the shops of cities on the seaboard are supplied, is derived chiefly from Cuba.

In the recent state honey is fluid; but on being kept, it forms a crystalline deposite, and is ultimately converted into a soft granular mass. In the shops it is found of every consistence, from that of a viscid liquid like thin syrup or oil, to that of lard or soft suet. Its colour is sometimes white, but usually yellowish, and occasionally of a brown or reddish tinge. It has a peculiar agreeable odour, varying somewhat with the flowers from which it was collected, and a very sweet feebly aromatic taste, which is followed by a slight prickling or sense of acrimony in the fauces. Its specific gravity is about 1.333. (*Duncan.*) Cold water dissolves it readily, alcohol with less facility. It contains crystallizable sugar analogous to that of the cane, uncrystallizable sugar, an aromatic principle, an acid, wax, and, according to Guibourt, a small quantity of mannite. The crystalline sugar may be obtained by treating granular honey with a small quantity of alcohol, which when expressed takes along with it the other ingredients, leaving the crystals nearly untouched. The same end may be attained by melting the honey, saturating its acid with carbonate of lime, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a larger proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation; and treated with nitric acid, is converted into oxalic acid.

In warm weather, honey, if not very pure, sometimes ferments, acquiring a pungent taste, and a deeper colour. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration may be detected by dilution with water, which dissolves the honey and leaves the starch at the bottom of the vessel. The nature of the deposite may be tested by the tincture of iodine. Water is said to be sometimes added to honey to increase its bulk. Its presence may be suspected from the greater thinness of the liquid, and its want of disposition to crystallize.

Medical Properties and Uses. Honey possesses the same medical properties with sugar, but is more disposed to run off by the bowels, and to occasion griping pain. Though largely consumed as an article of food, it is seldom employed medicinally, except as the vehicle of more active substances. Its taste and detergent qualities render it a useful addition to gargles, and it is sometimes employed as an application to foul ulcers, and in the form of enema.

MELISSA OFFICINALIS. Herba. *Dub.*

Balm.

Off. Syn. MELISSÆ OFFICINALIS FOLIA. *Ed.*

Melisse, *Fr.;* Garten-Melisse, *Germ.;* Melissa, *Ital.;* Torongil, *Span.*

Melissa. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Labiatæ.

Gen. Ch. Calyx dry, nearly flat above; with the upper lip sub-fastigiate. *Corolla,* upper lip somewhat arched, bifid; lower lip with the middle lobe cordate. *Willd.*

Melissa officinalis. Willd. *Sp. Plant.* iii. 146; Woodv. *Med. Bot.* p. 334. t. 119. Balm has a perennial root, which sends up annually several erect, quadrangular stems, usually branched towards the base, and a foot or two in height. The leaves are opposite, ovate or cordate, deeply serrate, pubescent; the lower on long footstalks, the uppermost nearly sessile. The flowers are white or yellowish, upon short peduncles, and in axillary whorls, surrounding only half the stem. The calyx is tubular, pentangular, and bilabiate, with the upper lip tridentate and flattened, the lower cut into two pointed teeth. The corolla is also tubular and bilabiate, the upper lip less convex and notched, the lower three-cleft.

The plant is a native of the South of Europe. It has been introduced into this country, where it is cultivated in gardens, and grows wild along the fences of our roads and lanes. For medical use the herb should be cut before the appearance of the flowers, which begin to expand in July.

In the fresh state, it has a fragrant odour very similar to that of lemons; but is nearly inodorous when dried. The taste is somewhat austere and slightly aromatic. The herb contains a minute proportion of a yellowish or reddish-yellow essential oil, which has its peculiar flavour in a very high degree. It contains also tannin, bitter extractive, and gum.

Medical Properties and Uses. Balm scarcely produces any remedial operation upon the system. The quantity of oil which it contains is not more than sufficient to communicate a pleasant flavour to the infusion, which forms an excellent drink in febrile complaints, and when taken warm tends to promote the operation of diaphoretic medicines. MENTHA PIPERITA. *U.S., Lond., Dub.*

Peppermint.

"Mentha piperita. Herba. *The herb.*" *U.S.*

Off. Syn. MENTHÆ PIPERITÆ HERBA. *Ed.*

Menthe poivrée, *Fr.;* Pfeffermünze, *Germ.;* Menta piperita, *Ital.;* Pimenta piperita, *Span.*

MENTHA. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Corolla* nearly equal, four-cleft; the broader segment emarginate. *Stamens* upright, distant. *Willd.*

Mentha piperita. Willd. *Sp. Plant.* iii. 79; Woodv. *Med. Bot.* p. 336. t. 120. Peppermint is a perennial herbaceous plant, with a creeping root, and erect, quadrangular, channeled, purplish, somewhat hairy stems, which are branched towards the top, and about two feet in height. The leaves are opposite, petiolate, ovate, serrate, pointed, smoother on the upper than the under surface, and of a dark green colour which is paler beneath. The flowers are small, purple, and disposed in terminal obtuse spikes, which are interrupted below. The calyx is tubular, furrowed, and five-toothed; the corolla is also tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its apex. The anthers are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The four-cleft germ is converted into four seeds, which are lodged in the calyx.

This species of mint is a native of Great Britain, whence it has been conveyed to the continent of Europe and to this country. In some parts of the United States, especially in New England, the western part of New York, Ohio, and New Jersey, it is largely cultivated for the sake of its volatile oil. We occasionally find it growing wild along the fences of our villages. The cultivators of this herb have observed, that in order to maintain its flavour in perfection, it is necessary to transplant the roots every three years. It should be cut for medical use in dry weather, about the period of the expansion of the flowers. These appear in August.

The herb, both in the recent and dried state, has a penetrating, grateful odour, somewhat resembling that of camphor. The taste is aromatic, warm, pungent, glowing, camphorous, bitterish, and attended with a sensation of coolness when air is admitted into the mouth. These properties depend on a volatile oil which abounds in the herb, and may be separated by distillation with water. (See *Oleum Menthæ Piperitæ.*) Peppermint also contains camphor, which rises with the oil. The virtues of the herb are imparted to water, and more readily to alcohol.

Medical Properties and Uses. Peppermint is a very grateful aromatic stimulant, much used for all the purposes to which medicines of this class are applied. To allay nausea, to relieve spasmodic pains of the stomach and bowels, to expel flatus, to cover the taste or qualify the nauseating or griping effects of other medicines, are among the most common of these purposes. The fresh herb, bruised and applied over the epigastrium, often allays sick stomach, and is especially useful in the cholera of children. The medicine may be given in infusion; but the volatile oil, either alone, or in some state of preparation, is almost always preferred.

MENTHA VIRIDIS. *U.S.*, *Lond.*, *Dub.*

Spearmint.

"Mentha viridis. Herba. *The herb.*" *U.S.*

Menthe a epi, *Fr.;* Grüne Münze, *Germ.;* Menta Romana, *Ital.;* Yerba buena puntiaguda, *Span.*

MENTHA. See MENTHA PIPERITA.

Mentha viridis. Willd. *Sp. Plant.* iii. 76; Woodv. *Med. Bot.* p. 338. t. 121. Spearmint, sometimes called simply *mint*, differs from the *M. piperita* chiefly in having sessile, or nearly sessile, lanceolate, naked leaves; elongated, interrupted, panicled spikes; setaceous bractes; and stamens longer than the tube of the corolla. Like the two preceding species, it is a native of England. In this country it is cultivated in gardens for domestic use, and in some places more largely for the sake of its oil. It also grows wild in low grounds in parts of the country which have been long settled. Its flowering season is August. According to Thomson, it should be cut in very dry weather, and, if intended for medical use, just as the flowers appear; if for obtaining the oil, after they have expanded.

The odour of spearmint is strong and aromatic, the taste warm and slightly bitter, less pungent than that of peppermint, but considered by some as more agreeable. These properties are retained for some time by the dried plant. They depend on a volatile oil which rises on distillation with water, and is imparted to alcohol and water by maceration. (See *Oleum Menthæ Viridis.*)

Medical Properties. The virtues and application of this plant are the same with those of peppermint.

Off. Prep. Aqua Menthæ Viridis, *Lond.*, *Dub.;* Infusum Menthæ Compositum, *Dub.;* Oleum Menthæ Viridis, *U.S.*, *Lond.*, *Dub.;* Spiritus Menthæ Viridis, *Lond.* W.

MENYANTHES. *U.S. Secondary.*

Buckbean.

"Menyanthes trifoliata. Radix. *The root.*" *U.S.*

MENYANTHES. *Sex. Syst.* Pentandria Monogynia.—*Nat.Ord.* Gentianeæ.

Gen. Ch. Corolla hirsute. *Stigma* bifid. *Capsule* one-celled. *Willd.*

Menyanthes trifoliata.. Willd. *Sp. Plant.* i. 811; Bigelow, *Am. Med. Bot.* iii. 55. The *buckbean* or *marsh trefoil* has a perennial, long, round, jointed, horizontal, branching, dark-coloured root, about as thick as the finger, and sending out numerous fibres from its under surface. The leaves are ternate, and stand upon long stalks, which proceed from the end of the root, and are furnished at their base with sheathing stipules. The leaflets are obovate, obtuse, entire or bluntly denticulate, very smooth, beautifully green on their upper surface, and paler beneath. The scape or flower stalk is erect, round, smooth, from six to twelve inches high, longer than the leaves, and terminated by a conical raceme of whitish somewhat rose-coloured flowers. The calyx is five parted; the corolla funnel-shaped, with a short tube, and a five-cleft, revolute border, covered on the upper side with numerous long, fleshy fibres. The anthers are red and saggittate; the germ ovate, supporting a slender style longer than the stamens, and terminating in a bifid stigma. The fruit is an ovate, two-valved, one-celled capsule containing numerous seeds.

This beautiful plant is a native both of Europe and North America, growing in boggy and marshy places which are always moist, and occasionally overflowed with water. It prevails, in the United States, from the northern boundary to Virginia. In this country the flowers appear in May, in England not till June or July. All parts of it are medicinal. The leaves are directed by the Edinburgh College, the whole plant by those of London and Dublin, the root by the Pharmacopœia of the United States.

The taste of buckbean is intensely bitter and somewhat nauseous, the odour of the leaves faint and disagreeable. The virtues of the plant depend on a bitter extractive matter which is dissolved by water and alcohol.

Medical Properties and Uses. With the ordinary properties of the bitter tonics, menyanthes unites a cathartic power, and in large doses is apt to vomit. It was formerly held in high estimation in Europe as a remedy in numerous complaints, among which were intermittents, rheumatism, scrofula, scurvy, dropsy, jaundice, and various cachectic and cutaneous affections. In most of these complaints it was administered under a vague impression of its alterative powers. It is scarcely ever employed in this country; but as it is a native plant, capable of useful application in cases where a combined tonic and purgative effect is demanded, it is desirable that our country practitioners should be aware of its properties, and prepared to take advantage of them should occasion offer.

The dose of the powdered leaves or root as a tonic is from twenty to thirty grains; of an infusion prepared with half an ounce to a pint of boiling water, from one to two fluidounces; and of the extract ten or fifteen grains, to be repeated three or four times a day. A drachm of the powder, or a gill of the strong decoction, generally purges, and often occasions vomiting.

W.

MEZEREUM. *U.S.*

Mezereon.

"Daphne mezereum. Radicis cortex. *The bark of the root.*" *U.S.*

Off. Syn. MEZEREI CORTEX. Daphne Mezereum. Radicis cortex. *Lond.;* DAPHNES MEZEREI CORTEX. *Ex radice. Ed.;* MEZEREON. DAPHNE MEZEREUM. Cortex. *Dub.*

Bois gentil, *Fr.;* Kellerhals, *Germ.;* Mezereo, *Ital.;* Mecereon, *Span.*

DAPHNE. *Sex. Syst.* Octandria Monogynia.—*Nat. Ord.* Thymeleæ.

Gen. Ch. *Calyx* none. *Corolla* four-cleft, withering, enclosing the stamens. *Drupe* one-seeded. *Willd.*

All the species of Daphne are possessed of active properties; and though the *D. Mezereum* is the only one recognised in the Pharmacopœias, either of the United States or Great Britain, at least two others, the *D. Gnidium* and *D. Laureola,* probably contribute to furnish the mezereon of commerce, and have been adopted as officinal in the French Codex.

1. *Daphne Mezereum.* Willd. *Sp. Plant.* ii. 415; Woodv. *Med. Bot.* p. 717. t. 245. This is a very hardy shrub, three or four feet high, with a branching stem, and a smooth dark-gray bark, which is very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate lanceolate, entire, smooth, of a pale green colour, somewhat glaucous beneath, and about two inches long. They are preceded by the flowers, which appear very early in spring, and sometimes bloom even amidst the snow. These are of a pale rose colour, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red colour, and contains a single round seed. Another variety produces white flowers and yellow fruit.

This species of Daphne is a native of Great Britain and the neighbouring continent, in the northern parts of which it is particularly abundant. It is cultivated in Europe both for medicinal purposes, and as an ornamental plant, and is occasionally found in our own gardens. It flowers in February, March, or April, according to the greater or less mildness of the climate.

2. *D. Gnidium.* Willd. *Sp. Plant.* ii. 420. In this species, called *garou* or *sain-bois* by the French, the leaves are linear lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicled racemes. The fruit is globular, dry, at first green, but ultimately black. The *D. Gnidium* grows in dry uncultivated places, in the South of Europe, and flowers in June. In France its bark is used indiscriminately with that of the former species.

3. *D. Laureola.* Willd. *Sp. Plant.* ii. 418; *Eng. Bot.* t. 119. The *D. Laureola* or *spurge laurel* is a strongly marked species, resembling the laurel, from which it derived its name. The leaves are thick-set, evergreen, lanceolate, acute, entire, coriaceous, smooth, and shining. The flowers are of a greenish colour, and disposed in axillary five-flowered racemes. The fruit is of a deep red colour, approaching to black. The plant is common in the moist woods of the southern and temperate parts of Europe. Its bark is said to be frequently substituted for that of the *D. Mezereum.*

The bark of the root is the part of the mezereon plant directed in the

Pharmacopœias. In Great Britain the root itself is frequently kept in the shops; and it was formerly brought to a considerable extent into the United States. But the mezereon with which our markets are now supplied is evidently the bark of the stem, and is brought chiefly from Germany. There is no reason to believe it inferior in virtues to that derived from the root. The berries and leaves of the plant are also possessed of active properties; and the former have sometimes proved fatal to children, who have been attracted by their beautiful colour. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to produce this effect. The French authors observe that fifteen are sufficient to kill a Frenchman.

Properties. Mezereon, as it comes to us, is usually in strips from two to four feet long and about an inch broad, sometimes flat, sometimes partially rolled, and always folded in bundles, or wrapped in the shape of balls. It is covered externally with a grayish or reddish-brown wrinkled epidermis, very thin, and easily separable from the bark. Beneath the epidermis is a soft greenish tissue. The inner bark is tough, pliable, fibrous, striated, and of a whitish colour. When fresh it has a nauseous smell, but in the dry state is nearly inodorous. Its taste is at first sweetish, but afterwards highly acrid, and even corrosive. It yields its virtues to water by decoction. Vauquelin ascertained the presence of a peculiar principle in the bark of the *D. Alpina.* This has subsequently been discovered in other species, and has received the name of *daphnin.* Gmelin and Bär found it in the bark of the *D. Mezereum* associated with wax, an acrid resin, a yellow colouring matter, a reddish-brown extractive matter, an uncrystallizable and fermentable sugar, a gummy matter containing azote, ligneous fibre, malic acid, and several malates. *Daphnin* is in prismatic crystals grouped together, colourless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water, ether, and alcohol, without odour, and of a bitter, somewhat austere taste. It is obtained by treating the alcoholic extract of the bark with water, decanting the solution, precipitating with subacetate of lead, filtering, decomposing the excess of the subacetate by sulphuretted hydrogen, again filtering, evaporating to dryness, submitting the residue to the action of anhydrous alcohol, and evaporating the alcoholic solution to the point of crystallization. Though daphnin is probably not inactive, it is not the principle upon which the virtues of mezereon chiefly depend. Vauquelin thinks that in the recent plant these reside in an essential oil, which by time and exposure is changed into a resin, without losing its activity. The acrid resin, observed by Gmelin and Bär, is probably the characteristic principle to which the bark owes its vesicating properties. It is obtained separate by boiling mezereon in alcohol, allowing the liquor to cool in order that it may deposite some wax which it has taken up, then distilling off the alcohol, and treating the residue with water, which leaves the resin. This is of a dark green, almost black colour, hard and brittle, and of an exceedingly acrid and permanent taste. In the isolated state, it is slightly soluble in water, and much more so when combined with the other principles of the bark. It appears, however, not to be a pure proximate principle, but rather a resinoid combination of an acrid vesicating fixed oil with another substance.

Medical Properties and Uses. The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic from time immemorial in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues, in cases which do not admit of the use of

Spanish flies. A small square piece of the bark, moistened with vinegar, is applied to the skin, and renewed twice a day till a blister is formed, and occasionally afterwards in order to maintain the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. An epispastic ointment is proposed by Guibourt, consisting of two drachms of the alcoholic extract of mezereon, nine ounces of lard, and one of wax. He employs the bark of the *D. Gnidium* (*garou*); but that of the other species will answer the same purpose. This preparation would form an excellent substitute for the savine ointment for maintaining the discharge from blistered surfaces. It may also be applied advantageously to obstinate, ill-conditioned, indolent ulcers.

Internally administered, mezereon is a stimulant capable of being directed to the skin or kidneys, and in large doses apt to excite purging, nausea, and vomiting. In overdoses it produces all the fatal effects of the acrid poisons. It had at one time much reputation as a remedy in the secondary stages of the venereal disease, and still enters as an ingredient into the officinal compound decoction of sarsaparilla. It has also been thought to act favourably as an alterative in scrofulous affections, chronic rheumatism, and obstinate diseases of the skin. For this purpose it is usually administered in decoction. (See *Decoctum Mezerei.*) Dr. Withering cured a case of difficult swallowing, arising from paralysis, by directing the patient to chew frequently small pieces of the root. The affection, which had continued three years, was removed in a month. The dose of the bark in substance may be stated at ten grains, though it is seldom used in this way.

MONARDA. *U.S.*

Horsemint.

"Monarda punctata. Herba. *The herb.*" *U. S.*

Monarda. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Calyx* five-toothed, cylindric, striate. *Corolla* ringent, with a long cylindric tube; *upper lip* linear, nearly straight and entire, involving the filaments, *lower lip* reflected, broader, three-lobed, the middle lobe longer. *Nuttall.*

Monarda punctata. Willd. *Sp. Plant.* i. 126; *Am. Med. Recorder*, vol. ii. p. 496. This is an indigenous perennial or biennial plant, with herbaceous, obtusely angled, downy, whitish, branching stems, which rise one or two feet in height, and are furnished with oblong lanceolate, remotely serrate, smooth, punctate leaves. The flowers are yellow, spotted with red or brown, and are disposed in numerous whorls, provided with lanceolate, coloured bractes, longer than the whorl.

The horsemint grows in light gravelly or sandy soils from New Jersey to Louisiana, and flowers from June to September. The whole herb is employed. It has an aromatic smell, and a warm, pungent, bitterish taste; and abounds in a volatile oil, which may be separated by distillation with water.

Medical Properties and Uses. Horsemint is stimulant and carminative; but is seldom used in regular practice. In the state of infusion it is occasionally employed in families as a remedy for flatulent colic and sick stomach, and for other purposes to which the aromatic herbs are applied. It was introduced into the primary catalogue of the United States Pharmacopœia on account of the volatile oil which it affords. (See *Oleum Monardæ.*)

MORI BACCÆ. *Lond.*

Mulberries.

"Morus nigra. *Baccæ.*" *Lond.*

Off. Syn. MORUS NIGRA. Baccæ. *Dub.*

Mures, *Fr.;* Schwarze Maulbeeren, *Germ.;* Morone, *Ital.;* Moras, *Span.*

Morus. *Sex. Syst.* Monœcia Tetrandria.—*Nat. Ord.* Urticæ, *Juss.;* Artocarpeæ, *R. Brown, Lindley.*

Gen. Ch. Male. *Calyx* four-parted. *Corolla* none. Female. *Calyx* four-leaved. *Corolla* none. *Styles* two. *Calyx* berried. *Seed* one. *Willd.*

Morus nigra. Willd. *Sp. Plant.* iv. 36; Woodv. *Med. Bot.* p. 712. t. 243. This species of mulberry is distinguished by its cordate ovate, or lobed, unequally toothed, and scabrous leaves. It is a tree of middle size, supposed to have been brought originally from Persia into Italy, and thence spread over Europe and America. Its leaves afford food for the silk-worm; and the bark of the root, which is bitter and slightly acrid, has been employed as a vermifuge, especially in cases of the tape-worm, in the dose of two drachms infused in eight ounces of boiling water. But the fruit is the only portion directed by the Colleges.

This is oblong oval, of a dark reddish-purple almost black colour; and consists of numerous minute berries united together and attached to a common receptacle, each containing a single seed, the succulent envelope of which is formed by the calyx. It is inodorous, has a sweet, mucilaginous, acidulous taste, and abounds in a deep red juice. The sourish taste is owing, according to Hermbstadt, to the presence of tartaric acid.

Medical Properties and Uses. Mulberries are refreshing and laxative, and serve to prepare a grateful drink well adapted to febrile cases. A syrup is prepared from them, and used as a pleasant addition to gargles in inflammation of the throat. They are, however, more used as food than medicine. Our native mulberry, the fruit of the *M. rubra,* is quite equal to that of the imported species. The *M. alba,* originally from China, and now extensively cultivated as a source of food for the silk-worm, bears a white fruit, which is sweeter and less grateful than the others.

MOSCHUS. *U.S., Lond., Ed., Dub.*

Musk.

"Moschus moschiferus. Concretum sui generis. *A peculiar concrete substance.*" *U.S.*

Musc, *Fr.;* Bisam, *Germ.;* Muschio, *Ital.;* Almizcle, *Span.*

Moschus. *Class* Mammalia. *Order* Pecora.

Gen. Ch. *Horns* none. *Fore teeth* eight in the lower jaw. *Tusks* one on each side in the upper jaw, projecting out of the mouth.

Moschus moschiferus. Gmelin, *Syst. Nat.* i. 172; Rees's *Cyclopædia.* This animal bears a close resemblance to the deer in shape and size. It is usually less than three feet in length, with haunches considerably more elevated than the shoulders. From its upper jaw two tusks project downwards out of the mouth, each about two inches long, curved backwards, and serving to extract the roots which are used as food by the animal. The ears are long and narrow and the tail very short. The fleece, which consists of strong, elastic, undulated hairs, varies in colour with the season, the age of the animal, and perhaps the place which it inhabits. The general colour is a deep iron gray. The individual hairs are whitish near the root, and fawn-coloured or blackish towards the tip. The musk is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two to three inches long, and from one to two broad, communicating externally by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, which is thrown into a number of irregular folds forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old seldom more than two drachms, and none in the young. The musk is secreted by the lining membrane, and in the living animal forms a consistent mass, which on the outside is compact and marked with the folds of the membrane, but is less firm towards the centre, where there is sometimes a vacant space. As first secreted it is probably in the liquid state, and a portion is occasionally forced out by the animal, to which it communicates its odour.

The musk deer inhabits the vast mountainous regions of central Asia, extending from India to Siberia, and from the country of the Turcomans to China. It is an active and timid animal, springing from rock to rock with surprising agility, and frequenting the snowy recesses, and most inaccessible crags of the mountains. Concealing itself during the day, it chooses the night for roaming in search of food; and though said to be abundant in its native regions, is taken with difficulty. It is hunted for its hide, as well as for the musk. As soon as the animal is killed the sac is cut off, and dried with its contents; and in this state is sent into the market.

Musk varies in quality with the country inhabited by the animal. That procured from the mountains on the southern borders of Siberia, and brought into the market through Russia, is comparatively feeble. The best is imported from China, and is said to be the product of Tonquin. A variety in-ermediate between these is procured in the Himalaya Mountains and Thibet, and sent to Calcutta. We derive our chief supply from Canton, though, when the drug is scarce, portions are occasionally brought hither from Europe.

Two varieties are distinguished in the market, the Chinese and Russian. Both come in sacs convex and hairy on one side, flat and destitute of hair on the other. The Chinese, which is the most highly valued, is in bags of a rounder shape, covered with brownish-yellow or reddish-brown hairs, and containing at most a drachm and a half of large grained, dark, strong-scented musk, having an ammoniacal odour. The Russian, which is contained in longer and larger bags, is small grained, of a clear yellow-brown colour, of a weaker and more fetid odour, with less smell of ammonia.

Properties. Musk is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous colour, resembling that of dried blood. The odour is peculiar, strong, penetrating, and so powerfully diffusive, that one part of musk communicates its smell to more than 3000 parts of inodorous powder. (*Fée.*) In some delicate individuals it produces headach and other disagreeable symptoms, and has even given rise to convulsions. The taste is bitter, disagreeable, and somewhat acrid.

The colour of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. It yields, upon analysis, a great number of proximate principles. Guibourt and Blondeau obtained water, ammonia, stearin, elaïn, cholesterin, an acid oil combined with ammonia, a volatile oil, muriates of ammonia, potassa, and lime, an uncertain acid saturated by the same bases, gelatin, albumen, fibrin, a highly carbonated matter soluble in water, a soluble calcareous salt with a combustible acid, carbonate and phosphate of lime, hair, and sand. (*Annal. de Phys. et de Chim.* ix. 327.) According to the same chemists, it contains 47 per cent. of volatile matter, thought by some to be chiefly ammonia, by others to be a compound of ammonia and volatile oil. Theimann obtained only from 10 to 15 per cent. But the quantity of volatile as well as of soluble matter varies exceedingly in different specimens. Thus Theimann found from 80 to 90 per cent. of matter soluble in water, Buchner only 54.5 per cent., and other chemists intermediate proportions. The proportion soluble in alcohol, as ascertained by different experimenters, varies from 25 to 62 per cent. Sulphuric ether is a good solvent. The watery infusion has a yellowish-brown colour, a bitterish taste, a strong smell of musk, and an acid reaction. The alcoholic tincture is transparent, and of a reddish-brown colour. Dr. A. T. Thomson is mistaken in stating that it has scarcely any of the peculiar odour of the medicine. The action of potassa upon musk is accompanied with the extrication of ammonia. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocire, but, according to Guibourt, without diminishing the activity of the medicinal principles. The correctness, however, of this opinion, is perhaps questionable; and it is advisable to preserve the musk as much as possible unaltered. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change.

Adulterations. The price of this medicine is so high, and the sources of supply so limited, as to offer strong temptations to adulteration; and it is said that little of the genuine, unmixed musk is to be found in the market. The sophistication commences with the Chinese, and is completed in Europe and this country. A common practice in the East is to open the sac, and to supply the place of the musk with an adulterated mixture. Sometimes the scrotum of the animal is filled with this mixture, and not unfrequently the sacs are manufactured out of the skin. Dried blood, from its resemblance in appearance to musk, is among the most common adulterations; but besides this, sand, lead, iron-filings, hair, animal membrane, tobacco, the dung of birds, wax, benzoin, storax, asphaltum, and other substances are introduced. These are mixed with a portion of musk, the powerful odour of which is diffused through the mass, and renders the discovery of the fraud sometimes difficult. It is said that the Chinese sometimes mix the musk of Tonquin with that of Siberia. The bags containing the drug should have the characters before described as belonging to the natural sac, and should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. Musk which burns with difficulty, which has a feeble odour, and a colour either pale or entirely black, which feels gritty to the finger, is very moist, or contains obvious impurities, should be rejected.

Medical Properties and Uses. Musk is stimulant and antispasmodic, increasing the vigour of the circulation, and exalting the nervous energy, without producing, either as an immediate or secondary effect, any considerable derangement of the purely cerebral functions. Its medical uses are such as may be inferred from its general operation. In almost all spasmodic diseases, so far as mere relaxation of spasm is desirable, it is more or less efficacious; but peculiar advantages may be expected from it in those cases in which a prostrate condition of the system, attended with great nervous agitation, or irregular muscular action, calls for the united influence of a highly diffusible stimulant and powerful antispasmodic. Such are very low cases of typhus disease, accompanied with subsultus tendinum, tremors, and singultus. Such also are many instances of gout in the stomach, and other spasmodic affections of this organ. In very obstinate hiccough we have found it more effectual than any other remedy; and have seen great advantage from its use in those alarming and dangerous convulsions of infants which have their origin in spasm of the intestines. It is said to have done much good combined with opium, and administered in very large doses in tetanus. Epilepsy, hysteria, asthma, pertussis, palpitations, cholera, and colic, are among the numerous spasmodic affections in which circumstances may render the employment of musk desirable. The chief obstacles to its general use are its very high price, and the great uncertainty as regards the degree of its purity. Musk was unknown to the ancients. Aëtius was the first writer who noticed it as a medicine. It was introduced into Europe through the Arabians, from whose language its name was derived.

It may be given in the form of pill or emulsion. The medium dose is ten grains, to be repeated every two or three hours. In the cases of children it may be given with great advantage in the form of enema. The tincture, which is an officinal preparation, is sometimes prescribed.

◆

MOXA. *Dub.*

Moxa.

"Artemisia Chinensis et A. Indica. *Folia.*" *Dub.*

The term *moxa* is employed to designate small masses of combustible matter, intended, by being burnt slowly in contact with the skin, to produce an eschar. They are of various forms, and made of different materials. The Chinese moxa is in small cones, from eight to twelve lines in height; and is prepared from the leaves of the *Artemisia Chinensis* and *A. Indica.* According to some authors, the part used is the down which covers the leaves and stems; but others, with greater probability, assert that it is a fine lanuginous substance prepared from the leaves by beating them in a mortar. A coarser and a finer product are obtained, the former of which is used for tinder, the latter worked up into moxa. A similar moxa has been made in France, by a similar process, from the leaves of the *A. vulgaris* or common European mugwort.

Various substitutes have been proposed for the Chinese moxa, all composed of some light, porous, soft, inflammable substance, which burns slowly, and thus allows the heat to be regulated according to the effect desired. Linen rolled into a cylinder, cotton formed into the same shape and enclosed in a piece of linen, cords of cotton in small masses of various shapes, and even common spunk made from the agaric of the oak, have been employed by different persons with the desired effect. But all these bodies are subject to the inconvenience of requiring to be constantly blown upon in order that their combustion may be sustained.

To remedy this defect, cotton impregnated with nitre has been recommended; and the moxa usually employed is prepared from this substance. It is important that the impregnation should be uniform, as otherwise different parts of the cylinder, burning with different degrees of rapidity, would produce unequal effects upon the skin. The following process is commonly employed in France. One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied, till all the liquid is evaporated. The cotton when perfectly dry is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sown firmly around it; and when used may be cut by a razor into transverse slices a few lines in length. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced.

The pith of the *Helianthus annuus*, or common sun-flower, has been proposed by M. Percy for the preparation of moxa, for which it is well adapted by the nitre which it naturally contains, and which enables it to burn without insufflation. The stem is cut into transverse sections about half an inch in thickness, which must be dried carefully, and afterwards kept in a perfectly dry place. They have this advantage in application, that, in consequence of the retention of the cortical portion, they may be held with impunity, while burning, between the fingers of the operator. They are, however, frequently defective in consequence of an insufficiency of nitre in the pith, or of the unequal inflammability of different parts of it. The stems of the plant employed should have attained perfect maturity.

M. Robinet has perfected the preparation of moxa, by combining the advantages of the two kinds last described. He rolls cotton round a small central cylinder of pith, and envelopes the whole in a piece of muslin, which is more or less firmly applied, according to the degree of compactness required. The cylinders thus made burn without assistance, uniformly, and with a rapidity proportionate to their firmness.

Dr. Jacobson, of Copenhagen, has recently proposed, as a substitute for the ordinary forms of moxa, small cylinders formed out of strips of paper embued with a solution of chromate of potassa; and cotton, impregnated with the solution of chlorate of potassa instead of nitre, is said to answer an excellent purpose. (*Journ. de Pharm.* xix. 608.)

Medical Use. Cauterization by fire, in the treatment of disease, has been commonly practised among savage and half civilized nations from the earliest periods of history, and has not been unknown as a remedy in the most polished communities. The ancient Egyptians and Greeks were acquainted with the use of moxa; and in China, Japan and other countries of Asia, it appears to have been employed from time immemorial. From these countries the early Portuguese navigators introduced it into Europe; and the term *moxa* is said to have been derived from their language, though supposed by some to be of Chinese origin. The true Chinese name is said to be *kiew.* (*Percy and Laurent.*) Within a few years the remedy has become very popular in France, and has attracted some attention in this country, though not generally employed. It acts on the principle of revulsion; relieving deep seated inflammation, and local irritation whether vascular or nervous, by inviting the current of excitement to the skin. In some cases it may also operate advantageously by the propagation of a stimulant impression to neighbouring parts in which the natural actions are enfeebled. The idea that moxa produces a peculiar effect by the substances which result from its combustion, is probably without foundation.

The celebrated Larrey is among those who have contributed most to bring this remedy into repute. The diseases in which it is recommended by this author are amaurosis, loss of taste, deafness, paralytic affections of the muscular system, asthma, chronic catarrh and pleurisy, phthisis, chronic engorgement of the liver and spleen, rachitis, diseased spine, coxalgia, and other forms of scrofulous and rheumatic inflammation of the joints. It has also been used advantageously in neuralgic affections, and is applicable to chronic complaints generally, in which powerful external revulsion is indicated.

The parts of the body upon which, according to Larrey, it should not be applied are the cranium when protected only by the skin and pericranium; the eye-lids, nose, and ears; the skin over the larynx, trachea, and mammary glands, over superficial tendons, projecting points of bones, and articular prominences in which the capsular ligament might be involved; the anterior surface of the abdomen; and the privates.

As a general rule it should be applied as near as possible to the seat of the disease; and, in neuralgic or paralytic cases, at the origin or over the course of the nerves proceeding to the part affected. Some advise that the cylinder be attached to the skin by some adhesive liquid; but a more general practice is to retain it in the proper position by a pair of forceps or other instrument. Larrey recommends that the skin around it be covered with a piece of moistened lint, having a hole in its centre to admit the base of the cylinder. The moxa should be set on fire at the summit, and the combustion sustained if necessary by the breath, the blow-pipe, or the bellows The size of the cylinder should vary, according to the effect desired, from half an inch to an inch or more in diameter, and from a few lines to an inch in height. Any degree of effect may be obtained, from a slight inflammation to the death of the skin, by regulating the time during which the moxa is allowed to burn. When a slough is required, it should be suffered to burn until consumed. The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe.

Myristica moschata. Willd. *Sp. Plant.* iv. 869; Woodv. *Med. Bot.* p. 698. t. 238. The nutmeg-tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves stand alternately on short footstalks, are oval lanceolate, pointed, entire, undulated, obliquely nerved, from two to three inches long and about an inch and a half broad, bright green on their upper surface, whitish beneath, and of an aromatic taste. The flowers are male and female upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish colour. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, with a smooth surface, at first pale-green, but yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy, and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and separating into two valves from the apex, discloses a yellowish or reddish reticulated membrane or arillus, commonly called *mace*, closely investing a slender, brown, shining shell, which contains the kernel or *nutmeg*. Not less than eight varieties of this species are said by Crawford to be cultivated in the East Indies; but they have not been well defined.

The *Myristica moschata* is a native of the Moluccas and other neighbouring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs have long been derived. The plant, however, is now cultivated in Sumatra, Java, Penang, and some other parts of the East Indies; and has been introduced into the Isle of France and Bourbon, the French colony of Cayenne, and some of the West India islands.

The tree is raised from the seed. It does not flower till the eighth or ninth year, after which it bears flowers and fruit together, without intermission; and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the female tree is grafted into all the young plants when about two years old, so as to ensure their early fruitfulness. In the Moluccas the tree yields three crops annually. The fruit is gathered by the hand, and the outside covering is rejected as useless. The mace is then carefully separated, so as to break it as little as possible, is flattened, and dried in the sun. It is afterwards sprinkled with salt water, with the view of contributing to its preservation. The nuts are dried in the sun or by ovens, and exposed to smoke, till the kernel rattles in the shell. They are then broken open, and the kernels having been removed, and steeped for a short time in a mixture of lime and water, probably in order to preserve them from the attack of worms, are next cleaned, and packed in casks or chests for exportation.

Nutmegs are brought to this country either directly from the East Indies, or indirectly through England and Holland. They are also occasionally imported in very small quantities from the West Indies.

Properties. The nutmeg, *nux moschata*, is of a roundish or oval shape, obtuse at the extremities, marked with vermicular furrows, of a grayish colour, hard, smooth to the touch, yielding readily to the knife or the grater, but not very pulverulent. When cut or broken it presents a yellowish surface, varied with reddish-brown, branching, irregular veins, which give to it a marbled appearance. These dark veins abound in oily matter, upon which the medicinal properties depend. The odour of nutmeg is delightfully fragrant, the taste warm, aromatic, and grateful. Its virtues are extracted by alcohol and ether. M. Bonastre obtained from 500 parts, 120 of a white insoluble oily substance (stearin), 38 of a coloured soluble oil (elaïn), 30 of volatile oil, 4 of acid, 12 of fecula, 6 of gum, 270 of lignin; and 20 parts were lost. (*Journ. de Pharm.* ix. 281.) The *volatile oil* is obtained by distillation with water. It is of a pale straw-colour, limpid, lighter than water, with a pungent spicy taste, and a strong smell of nutmeg. It consists of two oils, which may be separated by agitation with water, one rising to the surface, the other sinking to the bottom. Upon standing it deposites a stearoptene in the form of a crystalline crust, which is called by John *myristicin.* (*Berzelius, Trait. de Chim.*) The volatile oil of nutmegs is ranked among the officinal medicines by the Dublin College. By pressure with heat an oily matter is obtained from the kernels, which becomes solid on cooling, and is commonly though erroneously called *oil of mace.* It consists of fixed and volatile oil united. (See *Oleum Myristicæ.*) Both the volatile and expressed oils are imported from the East Indies.

It is said that nutmegs are often punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their greater levity. They are also apt to be injured by worms, which, however, attack preferably those parts which are least impregnated with the volatile oil. We are told that the Dutch heat them in a stove in order to deprive them of the power of germinating, and thus prevent the propagation of the tree. The small and round nutmegs are preferred to those which are large and oval. They should be rejected when very light, with a feeble taste and smell, worm eaten, musty, or marked with black veins.

A variety of nutmeg was formerly in the market, derived from the *M. tomentosa* of Willdenow, the *M. Malabarica* of Lamarck, distinguished from that just described by its much greater length, its elliptical shape, the absence of the brown veins, and its comparatively feeble odour, and disagreeable taste. It was called *male* or *wild nutmeg*, the other being designated as the *female* or *cultivated nutmeg.*

Mace is in the shape of a flat membrane irregularly slit, smooth, soft, flexible, of a reddish or orange-yellow colour, and an odour and taste closely resembling those of nutmeg. It consists, according to M. Henry, of an essential oil in small quantity; a fixed oil, odorous, yellow, soluble in ether, insoluble in boiling alcohol; another fixed oil, odorous, red, soluble in alcohol and ether in every proportion; a peculiar gummy matter, analogous to amydin and gum, constituting one-third of the whole mass; and a small proportion of ligneous fibre. Mace yields a volatile oil by distillation, and a fixed oil by pressure. Neumann found the former heavier than water. The latter is less consistent than the fixed oil of nutmegs. Mace is inferior when it is brittle, less than usually divided, whitish or pale yellow, or with little taste and smell.

Medical Properties and Uses. Nutmeg unites with the medicinal properties of the ordinary aromatics, considerable narcotic power. In the quantity of two or three drachms it has been known to produce stupor and delirium; and dangerous if not fatal consequences are said to have followed its free use in India. It is employed to cover the taste or correct the operation of other medicines, but more frequently as an agreeable addition to farinaceous articles of diet, and to various kinds of drink in cases of languid appetite, and delicate stomach. It is usually given in substance, and is brought by grating to the state of a powder. *Mace* possesses properties essentially the same with those of nutmeg, but is less used as a medicine. The dose of either is from five to twenty grains. As the virtues of nutmeg depend chiefly if not exclusively on the volatile oil, the latter may be substituted, in the dose of two or three drops, whenever a liquid preparation is desirable.

The ancients were wholly unacquainted with this spice; and Avicenna is said to be the first author by whom it is noticed.

MYROXYLON. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Leguminosæ.

Gen. Ch. *Calyx* bell-shaped, five-toothed. *Petals* five, the upper one larger than the others. *Germen* longer than the corolla. *Legume* with one seed only at the point. *Willd.*

Myroxylon Peruiferum. Willd. *Sp. Plant.* ii. 546; Lambert's *Illustrations*, A.D. 1821. p. 97. This is a tall and very beautiful tree, with a straight, smooth trunk, and branches nearly horizontal. The bark is of a gray colour, compact, heavy, and highly resinous; and has the aromatic flavour of the balsam. The leaves are alternate, and composed of two, three, four, and sometimes five pairs of leaflets, which are nearly opposite, ovate lanceolate, with a lengthened but somewhat blunt and emarginate apex, entire, smooth and shining, hairy on the under surface, marked with numerous transparent points, and placed on short footstalks. Many leaves terminate unequally, consisting of five, six, or nine leaflets. The common petioles are rather thick, and hairy. The flowers are white or rose-coloured, and disposed in axillary racemes, longer than the leaves. The fruit is a pendulous, straw-coloured legume, club-shaped, somewhat curved, terminating in the curved style, and globular near the extremity, where there is a single cell, containing a crescent-shaped seed.

The tree is a native of the warmer regions of South America, growing in various parts of Peru and New Granada, where it is called *quinquino* by the natives. The wood is employed in building, and is valuable for its durability. The bark and fruit are used to perfume apartments. The tree yields by incision a balsamic juice, which, when received in bottles, may be preserved in a liquid state for some years. This is called *white liquid balsam.* When this juice is deposited in mats or calabashes, as is commonly done in Carthagena and the mountains of Tolu, it becomes concrete, and acquires the name of *dry white balsam*, or *balsam of Tolu*, by which it is known in the shops. By boiling the bark in water. a dark coloured liquid is procured, which retains its fluid consistence, and is called *black Peruvian balsam.* According to Ruiz, from whose account the above details were derived, "there is no difference in these three balsams, excepting in the name, colour, and consistence." It is only the dark coloured liquid that is known with us by the name of *balsam of Peru*, and to this the following remarks are confined.

In stating that it is procured by boiling the bark in water, Ruiz does not speak from his own knowledge. A general opinion is, that it is prepared by decoction from the smaller branches. As brought into the United States, it is usually in tin canisters, with a whitish scum upon its surface, and more or less deposite, which, however, is dissolved with the aid of heat.

In a recent communication by M. Guibourt to the Society of Pharmacy at Paris, it is stated, on the authority of M. Bazire, that a product exactly resembling the dark coloured Peruvian balsam of commerce is collected largely in Guatemala, and thence sent to Peru. It is obtained from a tree belonging to the genus *Myrospermum* of Jacquin—*Myroxylon* of Linnæus—but specifically different from the *M. Peruiferum.*

Properties. Balsam of Peru is viscid like syrup or honey, of a dark reddish-brown colour, a fragrant odour, and a warm bitterish taste, leaving when swallowed a burning or prickling sensation in the throat. Its sp. gr. is from 1.14 to 1.15. When exposed to flame it takes fire, diffusing a white smoke, and a fragrant odour. Consisting chiefly of resin, essential oil, and benzoic acid, it is properly considered a balsam, though probably altered by heat. Alcohol in large proportion entirely dissolves it. Boiling water extracts the benzoic acid. From 1000 parts of the balsam, Stoltze obtained 24 parts of a brown nearly insoluble resinous matter, 207 of resin readily soluble, 690 of oil, 64 of benzoic acid, 6 of extractive matter, and a small proportion of water. The oil he considers to be of a peculiar nature, differing from the volatile, the fixed, and the empyreumatic oils.

Medical Properties and Uses. This balsam is a warm stimulating tonic and expectorant; and has been recommended in chronic catarrhs, certain forms of asthma, phthisis, and other pectoral complaints attended with debility. It has also been used in gonorrhœa, leucorrhœa, amenorrhœa, chronic rheumatism, and palsy. At present, however, it is little employed by American physicians. As an external application it has been found beneficial in chronic indolent ulcers. The dose is half a fluidrachm. It is best administered diffused in water by means of sugar and the yolk of eggs or gum Arabic. W.

MYRRHA. *U.S., Lond., Ed., Dub.*

Myrrh.

"Balsamodendron myrrha. Succus concretus. *The concrete juice.*" *U.S.*
Myrrhe, *Fr., Germ.;* Mirra, *Ital., Span.;* Murr, *Arab.;* Bowl, *Hindoost.*

Though myrrh has been employed from the earliest periods of history, the plant which yields it has not been certainly known till a very recent period. The *Amyris Kataf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient evidence. More recently Ehrenberg, a German traveller, met on the frontiers of Arabia Felix with a plant, from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From specimens of the plant taken by Ehrenberg to Germany, Nees of Esenbeck referred it to the genus Balsamodendron of Kunth, and named it *Balsamodendron Myrrha.* This genus was formed by Kunth from the *Amyris*, and includes the *Amyris Kataf* of Forskhal, which may possibly also produce a variety of myrrh. The new genus differs from the *Amyris*, chiefly in having the stamens beneath instead of upon the germ. It is not thought by De Candolle sufficiently distinct. For the generic character of Amyris, see *Elemi.*

Balsamodendron Myrrha. Fée, *Cours d' Hist. Nat. Pharm.* i. 641. This is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two lateral are much smaller than that at the end. The fruit is oval lanceolate, pointed, longitudinally furrowed, of a brown colour, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighbourhood of Gison, in dwarfish thickets, interspersed among the Acaciæ and Euphorbiæ. The juice exudes spontaneously, and concretes upon the bark.

Two varieties of myrrh are distinguished in the market—the *India* and the *Turkey myrrh*—the former imported from the East Indies, the latter from the Levant. It is said that the India myrrh is collected in Abyssinia, and thence taken to the ports of Hindostan, while that which goes under the name of Turkey myrrh, is brought from Arabia by the route of Egypt.

Properties. Myrrh is in small irregular fragments somewhat like tears, or in larger masses composed apparently of agglutinated portions differing somewhat in their shade of colour. When of good quality, it is reddish-yellow and translucent, of a strong peculiar somewhat fragrant odour, and a bitter aromatic taste. It is brittle and pulverizable, presenting, when broken, a shining surface, which in the larger masses is very irregular. Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously; and is not fusible by heat. Its specific gravity is stated at 1.36. Turkey myrrh, to the best of which the above description is applicable, generally much excels in quality that imported from the East Indies. The latter is much darker, more opaque, less odorous, and often abounds with impurities. We have seen pieces of India myrrh enclosing large crystals of common salt, as if the juice might have fallen from the tree and concreted upon the ground, where this mineral abounds. Is not this fact confirmatory of the statement, that the India myrrh is partly at least brought originally from Abyssinia, where we know that salt exists abundantly in some places upon the surface of the earth?

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish solution, which deposites the larger portion of the myrrh upon standing. The alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odour and taste. By distillation a volatile oil rises, having the peculiar flavour of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in the liquid alkalies, and when triturated with them in a crystalline state forms a tenacious liquid. Braconnot found 23 parts of an odorous bitter resin, and 77 of a peculiar gummy substance in the hundred. (*Fée Hist. Nat. Pharm.*) Pelletier gives as the result of his analysis, 34 per cent. of resin, with a small proportion of volatile oil, and 66 per cent. of gum. According to Brandes, it contains in one hundred parts, 2.60 of volatile oil, 22.24 of a soft, bitter resin, soluble in ether, 5.56 of a tasteless resin, insoluble in ether, 54.38 of gum with traces of various salts, 9.30 of tragacanthin (bassorin), besides salts of potassa and lime, water, and impurities.

Medical Properties and Uses. Myrrh is a stimulant tonic, with some tendency to the lungs, and perhaps to the uterus. Hence it is employed as an expectorant and emmenagogue, in debilitated states of the system, in the absence of febrile excitement or acute inflammation. The complaints in which it is usually administered are chronic catarrh, phthisis pulmonalis, humoral asthma, other pectoral affections in which the secretion of mucus is abundant but not easily expectorated, chlorosis, amenorrhœa, and the various affections connected with this state of the uterine function. It is generally given combined with the chalybeates or other tonics, and in amenorrhœa, very frequently with aloes. It is used also as a local application to spongy gums, the aphthous sore mouth of children, and various kinds of unhealthy ulcers. The dose is from ten to thirty grains, and may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Dr. Griffith, which has been introduced into the Pharmacopœias with the title of *Mistura Ferri Composita.* The watery infusion is also sometimes given, and an aqueous extract has been recommended as milder than the medicine in substance. The tincture is used chiefly as an external application.

NUX VOMICA. *U.S. Dub.*

Nux Vomica.

"Strychnos nux vomica. Semina. *The seeds.*" *U. S.*

Noix vomique, *Fr.;* Krähenaugen, Brechnüsse, *Germ.;* Noce vomica, *Ital.;* Nuez vomica, *Span.*

STRYCHNOS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Apocyneæ.

Gen. Ch. *Corolla* five-cleft. *Berry* one-celled, with a ligneous rind. *Willd.*

Strychnos Nux Vomica. Willd. *Sp. Plant.* i. 1052; Woodv. *Med. Bot.* p. 222. t. 79. This tree is of a moderate size, with numerous strong branches covered with a smooth, dark gray bark. The young branches are long, flexuous, very smooth, dark green, and furnished with oval roundish, entire, smooth, and shining leaves, having three or five ribs, and placed opposite to each other on short footstalks. The flowers are small, white, funnel-shaped, and disposed in terminal corymbs. The fruit is a round berry, about as large as an orange, covered with a smooth, yellow, or orange-coloured, hard, fragile rind, and containing numerous seeds embedded in a juicy pulp.

The tree is a native of the East Indies, growing in Malabar, on the coast of Coromandel, in Ceylon, in numerous islands of the Indian Archipelago, in Cochin China, and other neighbouring countries. The wood and the root are very bitter, and employed in the East Indies for the cure of intermittents. The *radices colubrinæ*, and *lignum colubrinum*, of the older writers, which have been long known in Europe as narcotic poisons, are ascribed by some writers to this species of Strychnos, under the impression that it is identical with the *S. Colubrina*, to which Linnæus refers them. They have been ascertained by Pelletier and Caventou to contain a large quantity of strychnia. The only officinal portion of the plant is the seeds, and to these it is that the title of nux vomica is applied.

They are flat, circular, about three quarters of an inch in diameter, and two or three lines in thickness, generally somewhat curved, with a depression on one side, and a corresponding prominence on the other. They are thickly covered with fine, silky, shining, ash-coloured or yellowish-gray hairs, attached to a thin fragile coating, which closely invests the interior nucleus or kernel. This is very hard, horny, usually whitish and semitransparent, sometimes dark coloured and opaque, and of very difficult pulverization. The seeds are destitute of odour, but have an acrid very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. Nux vomica has been analyzed by several chemists, but most accurately by Pelletier and Caventou, who discovered in it two alkaline principles, *strychnia* and *brucia*, united with a peculiar acid which they named *igasuric*. Its other constituents are a yellow colouring matter, a concrete oil, gum, starch, bassorin, a small quantity of wax, and, according to M. Corriol, zumic acid. Strychnia and brucia are its active principles, and as they have been employed in the separate state, deserve a particular consideration.

Strychnia was discovered by Pelletier and Caventou, A.D. 1818, both in the nux vomica and bean of St. Ignatius, and received its name from the generic title of the plants (*Strychnos*), to which these two products belong. According to these chemists, it exists much more abundantly in the bean of St. Ignatius than in the nux vomica, the former yielding 1.2 per cent., the latter only 0.4 per cent. of the alkali. Pure strychnia crystallizes in quadrilateral prisms, terminated by quadrilateral pyramids. Rapidly crystallized, it is in the form of a white granular powder. It is permanent in the air, inodorous, but excessively bitter, with a metallic after taste. So intense is the bitterness, that one part of strychnia communicates a sensible taste to 600,000 parts of water. It is neither volatile nor fusible, being melted by heat only at the moment of decomposition, which takes place, however, at a comparatively low temperature. It is soluble in 6667 parts of water at 50°, and about 2500 parts at the boiling point. Alcohol and the volatile oils dissolve it freely, ether very sparingly. The acids unite with it to form crystallizable salts. Its ultimate constituents are carbon, nitrogen, hydrogen, and oxygen. It may be obtained by the following process.

Prepare a decoction of nux vomica previously rasped, or what is better, boil the alcoholic extract in water. Treat the solution with an excess of subacetate of lead, which precipitates various foreign matters, leaving the strychnia and brucia dissolved. Throw down the excess of lead by hydrosulphuric acid (*sulphuretted hydrogen*); filter the solution; boil it in order to expel the excess of hydrosulphuric acid; then boil with magnesia, which decomposes the salts of strychnia and brucia, and precipitates these alkalies mingled with the excess of magnesia. Collect the precipitate on a filter, wash it with cold water, and treat it with boiling alcohol, which dissolves the vegetable alkalies, leaving the magnesia. Filter the liquor while still hot, and evaporate it to dryness. A mixture of strychnia, brucia, and colouring matter is thus obtained. Treat the mixture with cold dilute alcohol, which dissolves the brucia and colouring matter, leaving the strychnia in the form of a powder. This may be purified by dissolving it in boiling rectified alcohol, which on cooling deposites the strychnia, and yields still more by evaporation; while a small quantity of brucia which had escaped the weak alcohol, remains in the mother liquor. To purify it still further it may be dissolved in a diluted acid, the saline solution treated with animal charcoal, and precipitated by an alkali; and the precipitated strychnia washed, dissolved in alcohol, and obtained in a crystalline state by evaporation.

The salts of strychnia are very soluble, intensely bitter, and powerful in their action on the system. They are precipitated from their solutions by tannin. The sulphate is sometimes employed. It is soluble in less than six times its weight of cold water, and consists of 9.5 parts of acid and 90.5 of base in the hundred. The mineral acids, acetic, tartaric, and citric acids, added to strychnia, render it more soluble, and therefore more energetic in its action on the system.

Strychnia is, from its high price, very liable to be adulterated. It should be entirely soluble in alcohol and the diluted acids, and should leave no residue when submitted to a calcining heat, with access of air. Magnesia and phosphate of lime are said to be among the most frequent adulterations. When entirely pure, it is not reddened by nitric acid; but a very small proportion of brucia, which can hardly be considered as an adulteration, is sufficient to impart this property. Robiquet states that all adulterations may be avoided by purchasing strychnia in the crystallized state. (*Journ. of Phil. Col. of Pharm.* vi. 232.)

Brucia was discovered by Pelletier and Caventou, first in the bark called *false Angustura*, (see *Angustura*,) and subsequently, associated with strychnia, in the nux vomica and bean of Saint Ignatius. It is crystallizable; without smell, but of a permanent, harsh very bitter taste; soluble in 850 parts of cold, and 500 of boiling water; and very soluble in alcohol, whether hot or cold. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. It forms crystallizable salts with the acids. Concentrated nitric acid produces with brucia or its salts an intense crimson colour, which changes to yellow by heat, and upon the addition of protomuriate of tin becomes violet. These effects are peculiar to brucia, and if produced with strychnia, evince the presence of the former alkali. Brucia is analogous in its operation to strychnia, but possesses, according to M. Andral, jun., only about one-twelfth of its strength, when the latter principle is entirely pure. It is therefore seldom employed; and it is unnecessary to insert a process for its preparation. It is sufficient to observe, that it may be procured from false Angustura bark, in a manner essentially the same with that in which strychnia is procured from the nux vomica, with this difference, that the alcoholic extract obtained from the magnesian precipitate should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which take up the colouring matter, leaving the oxalate of brucia. This is decomposed by magnesia, and the brucia separated by alcohol, which, by spontaneous evaporation, yields it in the state of crystals.

Medical Properties and Uses. Nux vomica is very peculiar in its operation upon the system. It appears to be chiefly directed to the nerves of motion, probably through the medium of the spinal marrow. When given in a quantity sufficient to bring the system under its influence, it produces involuntary contractions of the muscles, which are usually of that permanently rigid character which we observe in tetanus; but at the same time there occur frequent and sometimes violent starts or muscular spasms, alternating with intervals of relaxation, as if the patient had received a shock of electricity. A sense of heat in the stomach, constriction of the abdomen, tightness of the chest, and retention of urine are also frequently experienced, to a greater or less extent, according to the quantity of the medicine administered. Given to the inferior animals in fatal doses it produces great anxiety, difficult and confined breathing, retching to vomit, universal tremors, spasmodic action of the muscles, and ultimately violent convulsions. Death is supposed to take place from a suspension of respiration, resulting from a spasmodic constriction of the muscles concerned in the process. Upon dissection, no traces of inflammatory action are observable, unless large quantities of the nux vomica have been swallowed, when the stomach appears inflamed. A division of the spinal marrow near the occiput, does not prevent the peculiar effects of the medicine, so that the intervention of the brain is not essential to its action. That it enters the circulation and is brought into contact with the parts upon which it acts, is rendered evident by the experiments of Magendie and others.

It has long been employed in India, and was known as a medicine to the Arabian physicians. On the continent of Europe it has at various times been recommended as an antidote to the plague, and as a remedy in intermittents, worms, mania, hypochondriasis, hysteria, rheumatism, hydrophobia, and dysentery; but in none of these complaints is it now much employed. It is said to have effectually cured obstinate spasmodic asthma. Its peculiar influence upon the nerves of motion, to which the public attention was first called by Magendie, suggested to M. Fouquier, a French physician, the application of the remedy to paralytic affections; and his success was such as to induce him to communicate to the public the result of his experience. Others have subsequently employed it with variable success; but the experience in its favour so much predominates, that it may now be considered a standard remedy in palsy. It is a singular fact, attested by numerous witnesses, that its action is directed more especially to the paralytic part, exciting contraction in this before it is extended to other muscles. The medicine, however, should be administered with judgment, and never given in cases depending on inflammation or organic lesion of the brain or spinal marrow, until after the removal of the primary affection by bleeding or other depletory measures. It has been found more successful in general palsy and paraplegia than in hemiplegia, and has frequently effected cures in palsy of the bladder, incontinence of urine from paralysis of the sphincter, in amaurosis, and other cases of partial palsy.

Nux vomica may be given in powder in the dose of five grains, repeated three or four times a day, and gradually increased till its effects are experienced. In this form, however, it is very uncertain; and fifty grains have been given with little or no effect. It is most readily reduced to powder by filing or grating; and the raspings may be rendered finer by first steaming them, then drying them by stove heat, and lastly rubbing them in a mortar.

The alcoholic extract is more convenient and more certain in its operation. From half a grain to two grains may be given in the form of pill, repeated as before, and gradually increased. (See *Extractum Nucis Vomicæ.*) The watery extract is comparatively feeble.

Strychnia has recently been much used, and possesses the advantage of greater certainty and uniformity of action. Its effects are precisely similar. With the exception of prussic acid, it is perhaps the most violent poison with which we are acquainted, and should therefore be administered with great caution. Dr. Bardsley bears very decided testimony to its favourable effects in palsy. He gave it in thirty-five cases, of which twenty-two were hemiplegia, and thirteen paraplegia; of the former, twelve were cured and eight considerably relieved; of the latter, eleven were cured and one relieved. The duration of the treatment was from six weeks or less to three months. Strychnia has also been highly recommended in the palsy resulting from the poisonous action of lead. The dose is from one-twelfth to one-sixth of a grain, repeated twice or three times a day, and gradually increased. Dr. Bardsley began with one-sixth of a grain, and seldom increased the dose to half a grain, three times a day, without producing spasmodic symptoms. The system is not so soon habituated to its impression as to that of the narcotics generally, so that after its effects are experienced it is unnecessary to go on increasing the dose.

Strychnia has been applied externally with advantage in amaurosis. It should be sprinkled upon a blistered surface near the temples, in the quantity of half a grain or a grain morning and evening, and the quantity may be gradually augmented. It has also been given internally with favourable results in the same complaint. The best form of administration is that of pill, in consequence of the excessive bitterness of the solution. Strychnia may, however, be given, dissolved in alcohol, or in water by the intervention of an acid.

Brucia may be used for the same purposes with strychnia in the dose of one grain twice or three times a day. Dr. Bardsley found that the quantity of two grains three or four times a day, was seldom exceeded without the occurrence of the characteristic effects of the medicine. Magendie has found this alkali very useful in small doses as a tonic. He employed for this purpose, one-eighth of a grain, frequently repeated.

◆

OLEA.

Oils.

These are liquid or solid substances, characterized by an unctuous feel, inflammability, and the property of leaving a greasy stain upon paper. They are divided into two classes, the *fixed* and *volatile*, distinguished, as their names imply, by their different habitudes in relation to the vaporizing influence of caloric.

1. OLEA FIXA. *Fixed Oils.*

The oils thus designated by the Edinburgh Pharmacopœia, are less correctly termed Olea expressa, *expressed oils*, by the London and Dublin Colleges; for they are not obtained exclusively by expression; and this process is sometimes employed in procuring the volatile oils. They are not designated as a class in the United States Pharmacopœia.

The fixed oils, though existing in greater or less proportion in various parts of plants, are furnished for use exclusively by the fruit; and, as a general rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press, by exposing them to a moderate heat, so as to render the oil more liquid, and thus enable it to flow out more readily.

The consistence of the fixed oils varies from that of tallow to perfect fluidity; but by far the greater number are liquid at ordinary temperatures. They are somewhat viscid, transparent, and usually of a yellowish colour, which disappears when they are treated with animal charcoal. When pure they have little taste or smell. They are lighter than water, varying in specific gravity from 0.913 to 0.936. (*Berzelius.*) They differ very much in their point of congelation, olive oil becoming solid a little above 32° F., while linseed oil remains fluid at 4° below zero. They are not volatilizable without decomposition. At about 600° they boil, and are converted into vapour, which, when condensed, is found to contain a large proportion of oleic and margaric acids together with benzoic acid, another volatile acid, and an empyreumatic oil. Exposed to a red heat, in close vessels, they yield, among other products of the destructive distillation of vegetables, a large quantity of the combustible compounds of carbon and hydrogen. Heated in the open air they take fire, burning with a bright flame, and producing water and carbonic acid. When kept in air-tight vessels, they remain unchanged for a great length of time; but exposed to the atmosphere, they attract oxygen, and ultimately become concrete. Some, in drying, lose their unctuous feel, and are converted into a transparent, yellowish, flexible solid. These are called drying oils. Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste and unpleasant smell. This change is owing to the formation of an acid, from which the oil may be freed by boiling it for a short time with hydrate of magnesia and water. The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they dissolve sulphur and phosphorus. Chlorine and iodine are converted by them into muriatic and hydriodic acids, which reacting upon the oils increase their consistence, and ultimately render them as hard as wax. The stronger acids decompose them, giving rise, among other products, to the oleic and margaric acids. Boiled with diluted nitric acid, they are converted into malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They combine with salifiable bases; but at the moment of combination undergo a change, by which they are converted into a peculiar substance, called glycerin, and into the oleic, margaric, and perhaps stearic acids, which unite with the base employed. The compounds of these acids with potassa and soda are called soaps. (See *Sapo* and *Emplastrum Plumbi.*) The fixed oils dissolve many of the vegetable alkalies, the volatile oils, resin, and other proximate principles of plants. They have been ascertained by Chevreul to consist of two distinct substances, one of which is liquid at ordinary temperatures, and therefore called *elaïn*, (from ελαιον, oil,) the other solid, and called *stearin*, (from στέαρ, suet). These are found equally in animal oils; and the mode of obtaining them, with their distinctive properties, is treated of under the head of *Adeps*, to which the reader is referred. These principles, however, are not absolutely identical in the different oils, and have different points of congelation and liquefaction, according to the substance from which they are derived. (*Berzelius.*) The ultimate constituents of the fixed oils are carbon, hydrogen, and oxygen, the hydrogen being in much larger proportion than is necessary to form water with the oxygen. Those which are least fusible contain most carbon and least oxygen; and, according to Saussure, their solubility in alcohol is greater in proportion to their amount of oxygen. (*Berzelius.*) Some of them contain a very minute proportion of nitrogen.

2. OLEA VOLATILIA. *Volatile Oils.*

These are sometimes called *distilled oils*, from the mode in which they are usually procured; sometimes *essential oils*, from the circumstance that they possess, in a concentrated state, the properties of the plants from which they are derived. In the Pharmacopœias of the United States and London, the former title has been adopted; in that of Dublin, the latter; the Edinburgh College uses the term *volatile oils*.

They exist in all odoriferous vegetables, sometimes pervading the whole plant, sometimes confined to a single part; in some instances contained in distinct cellules, and preserved after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as they are formed. Occasionally two or more are found in different parts of the same plant. Thus the orange tree produces one volatile oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing in distinct cellules, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally procured by distillation with water. (See *Olea Destillata.*)

The volatile oils are usually yellowish, but sometimes brown, red, green, or even blue, and occasionally colourless. They have a strong odour, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent; and when they are diluted, is often gratefully aromatic. The greater number are lighter than water; some are heavier; and their sp. gr. varies from 0.847 to 1.17.* They partially rise in vapour at ordinary temperatures, diffusing their peculiar odour, and are completely volatilized by heat. Their boiling point is various, generally as high as 320° F. and sometimes higher; but most of them rise readily with the vapour of boiling water. When distilled alone, they almost always undergo partial decomposition. They differ also in their point of congelation. A few are solid at ordinary temperatures, several become so at 32° F., and many remain liquid considerably below this point. Heated in the open air, the volatile oils take fire, and burn with a bright flame, attended with much smoke. Exposed at ordinary temperatures, they absorb oxygen, assume a deeper colour, become thicker and less odorous, and are ultimately converted into resin. This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation.

The volatile oils are very slightly soluble in water. Agitated with this fluid they render it milky; but separate upon standing, leaving the water impregnated with their odour and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing them. Trituration with magnesia or its carbonate renders them much more soluble, probably in consequence of presenting, by their minute division, a more extensive surface to the action of the solvent. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. Most of them are very soluble in alcohol, and in a degree proportionate to its freedom from water. The oils which contain no oxygen are scarcely soluble in diluted alcohol; and, according to Saussure, their solubility generally in this liquid is proportionate to the quantity of oxygen which they contain. They are readily dissolved by ether.

---

* The oil of the *Gaultheria procumbens*, a native plant, is said to have the extraordinary sp. gr. of 1.17. *Journ. of the Phil. Col. of Pharm.* iii. 199.

The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposite them on cooling. By long boiling with sulphur they form brown, unctuous, fetid substances, formerly called *balsams of sulphur.* They absorb chlorine, which converts them into resin, and then combines with the resin. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with several of those from the vegetable kingdom. With the exception of the oil of cloves they do not combine directly with salifiable bases; but when treated with a caustic alkali, they are converted into resin, which unites with the alkali to form a kind of soap. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resin. The volatile oils dissolve many of the proximate principles of plants and animals; such as the fixed oils and fats, resin, camphor, and several of the vegetable alkalies.

The volatile, like the fixed oils, consist of distinct principles, which are congealed at different temperatures, and may be separated by compressing the frozen oil between the folds of bibulous paper. The solid matter remains within the folds; and the fluid is absorbed by the paper, from which it may be separated by distillation with water. The name of *stearoptene* has been proposed for the former, that of *eleoptene* for the latter. The solid crystalline substances deposited by certain volatile oils upon standing, usually considered as camphor, are examples of stearoptene. Some oils, under the influence of water, deposite crystalline bodies which appear to be hydrates of the respective oils.

The ultimate constituents of the volatile oils are usually carbon, hydrogen, and oxygen. Some, as the oils of turpentine and copaiba, in their purest state, contain only carbon and hydrogen. Several, according to De Saussure, have a very minute proportion of nitrogen in their composition.

The volatile oils are often sophisticated. Among the most common adulterations are fixed oils, resinous substances, and alcohol. The fixed oils may be discovered by the permanent stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol is present, the oil becomes milky when agitated with water, and after the separation of the liquids, the water occupies more space, and the oil less than before. The following method of detecting alcohol has been proposed by M. Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remain for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than four per cent. If it disappear in five minutes, the oil contains more than four per cent. of alcohol; if in less than a minute, twenty-five per cent. or more. Sometimes oils of little value are mixed with those which are costly. The taste and smell afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of their purity. When oils of which one is lighter and one heavier than water, are mixed, they are separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities. But it sometimes happens that an unadulterated oil may thus be separated into two portions. When oil of turpentine is used as the adulteration, it may be known by remaining in part undissolved, when the mixture is treated with three or four times its volume of alcohol of the sp. gr. 0.84.

Volatile oils may be preserved without change in small well-stopped bottles, entirely filled with the oil, and excluded from the light. W.

OLEUM AMYGDALÆ. *U. S.*

Oil of Almonds.

"Amygdalus communis. Nucleorum oleum fixum. *The fixed oil of the kernels.*" *U. S.*

Off. Syn. OLEUM AMYGDALARUM, *Lond.*, *Dub.*; OLEUM AMYGDALI COMMUNIS, *Ed.*

Huile d'amandes, *Fr.*; Mandelöl, *Germ.*; Olio di mandorle, *Ital.*; Aceyte de almendras, *Span.*

See AMYGDALA.

This oil is obtained equally pure from sweet and bitter almonds. In its preparation, the almonds, after having been deprived of a reddish-brown powder adhering to their surface, by rubbing them together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then submitted to pressure in canvass sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. The London College directs the oil to be prepared by macerating the almonds in cold water for twelve hours, bruising them, and then expressing without heat. The Edinburgh and Dublin Colleges employ the same process, omitting the previous maceration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove previously to expression. The oil is thus obtained free from colour, but in no other respect better. Bitter almonds, when treated in this way, are said to impart a smell of hydrocyanic acid to the oil. With regard to these, therefore, the process is objectionable. M. Boullay obtained fifty-four per cent. of oil from sweet almonds, Vogel twenty-eight per cent. from bitter almonds.

The oil of almonds is clear and colourless, or slightly tinged of a greenish-yellow, is nearly inodorous, and has a bland sweetish taste. It remains liquid at temperatures considerably below the freezing point of water. Its sp. gr. is from 0.917 to 0.92.

It may be used for the same purposes with olive oil; and when suspended in water by means of mucilage or the yolk of eggs and loaf sugar, forms a very pleasant emulsion, useful in catarrhal and other pulmonary affections attended with cough. From a fluidrachm to a fluidounce may be given at a dose.

OLEUM BUBULUM. *U.S.*

Neats-foot Oil.

"Bos domesticus. Oleum ex ossibus præparatum. *The oil prepared from the bones.*" *U.S.*

Huile de pied de bœuf, *Fr.;* Ochsenfussefett, *Germ.*

Neats-foot oil is obtained by boiling in water for a long time the feet of the ox, previously deprived of their hoof. The fat and oil which rise to the surface are removed, and introduced into a fresh portion of water heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to cool, the fat concretes, and the oil is removed and strained, or filtered through layers of small fragments of charcoal free from powder.

This oil is yellowish, and when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is therefore very useful for greasing machinery in order to prevent friction.

It was introduced into the officinal catalogue of the United States Pharmacopœia as an ingredient of the ointment of nitrate of mercury.

OLEUM CAJUPUTI. *U.S. Secondary.*

Cajuput Oil.

"Melaleuca cajuputi. Oleum volatile. *The volatile oil.*" *U.S.*

Off. Syn. CAJUPUTI OLEUM. Melaleuca Cajuputi. Oleum essentiale. *Lond.;* MELALEUCÆ LEUCADENDRI OLEUM VOLATILE. *Ed.;* MELALEUCA LEUCADENDRON. Oleum volatile Cajeput. *Dub.*

Huile de cajéput, *Fr.;* Kajeputöl, *Germ.;* Olio di cajeput, *Ital.;* Kayuputieh, *Malay.*

Melaleuca. *Sex. Syst.* Polyadelphia Icosandria.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. *Calyx* five-parted, semi-superior. *Corolla* five-petalled. *Stamens* about forty-five, very long, conjoined in five bodies. *Style* single. *Capsule* three-celled. *Seeds* numerous. *Roxburgh.*

It was long supposed that the oil of cajuput was derived from the *Melaleuca leucadendron;* but from specimens of the plant which really yields this medicine, sent from the Moluccas and cultivated in the botanical garden of Calcutta, it appears to be a distinct species, upon which the trivial name of *Cajuputi* has been conferred. It corresponds with the *arbor alba minor* of Rumphius, and is a smaller plant than the *M. leucadendron.*

Melaleuca Cajuputi. Rumphius, *Herbar. Amboinense,* tom. ii. tab. 17; Roxburgh, *Trans. Lond. Med. Bot. Soc.,* A. D., 1829; *Journ. of the Phil. Col. of Pharm.,* vol. i. p. 193. This is a small tree, with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish-ash colour, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes, like the birch tree. The leaves have short footstalks; are alternate, lanceolate, when young sericeous, when full grown smooth, deep green, three and five-nerved, slightly falcate, entire, from three to five inches long, from one half to three quarters of an inch broad; and when bruised exhale a strong aromatic odour. The flowers, which are small, white, inodorous, and sessile, are disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bractes. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx.

This species of Melaleuca is a native of the Moluccas, and other neighbouring islands. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves, and the extensive use made of it in India, render it very costly.

Properties. Cajuput oil is very fluid, transparent, of a fine bluish-green colour, a lively and penetrating odour analogous to that of camphor, and a warm pungent taste. It is very volatile, lighter than water, (of the sp. gr. 0.978 at 48°,) and burns without any residue. The green colour is ascribed by some writers to the presence of a salt of copper derived from the vessels in which the distillation is performed; but neither Brande nor Gœrtner could detect copper by chemical reagents. M. Lesson, who witnessed the process for preparing the oil at Bouro, attributes its colour to chlorophylle, or some analogous principle, and states that it is rendered colourless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a Melaleuca cultivated at Paris.

The high price of cajuput oil has led to its occasional adulteration. The oil of rosemary, or that of turpentine, impregnated with camphor, and coloured with the resin of milfoil, is said to be employed for the purpose.

Medical Properties and Uses. This oil is highly stimulant, producing when swallowed a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is very highly esteemed by the Malays and other people of the East, who consider it a universal panacea. (*Lesson, Journ. de Chim. Med.* 1827.) They are said to employ it with great success in epilepsy and palsy. (*Ainslie.*) The complaints to which it is best adapted are probably chronic rheumatism, and spasmodic affections of the stomach and bowels, unconnected with inflammation. It has been highly extolled as a remedy in spasmodic cholera. Diluted with an equal proportion of olive oil, it is applied externally to relieve gouty and rheumatic pains. Like most other highly stimulating essential oils, it relieves toothach, if introduced into the hollow of the carious tooth. It is little used in the United States. The dose is from one to five drops, given in emulsion, or upon a lump of sugar. W.

OLEUM CARYOPHYLLI. *U.S.*

Oil of Cloves.

"Eugenia caryophyllata. Gemmarum floralium oleum volatile. *The volatile oil of the flower-buds.*" *U.S.*

Off. Syn. CARYOPHYLLORUM OLEUM. *Lond.;* EUGENIÆ CARYOPHYLLATÆ OLEUM VOLATILE. Ex floribus nondum explicitis. *Ed.;* EUGENIA CARYOPHYLLATA. Oleum volatile. *Dub.*

Huile de girofle, *Fr.;* Nelkenöl, *Germ.;* Olio di garofani, *Ital.;* Aceyte de clavos *Span.*

See CARYOPHYLLUS.

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. The product of good cloves is said to be about one-sixth of their weight. The oil was formerly brought from Holland or the East Indies; but since the introduction of the Cayenne cloves into our markets, the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country; and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties. Oil of cloves, when recently distilled, is very fluid, clear, and colourless, but becomes yellowish by exposure, and ultimately brown. As found in our shops it is frequently of a reddish-brown colour, answering in appearance to the oil described by Lewis, and after him by other British writers on the Materia Medica, as derived from the Dutch. In the properties of taste and smell, the oil resembles cloves, but is comparatively less pungent. The taste of the Dutch oil of cloves is more pungent and fiery than that freshly obtained by distillation, owing, as is supposed, to the presence of a portion of the resin. The sp. gr. of the oil, according to Bonastre, is 1.061. It is one of the least volatile of the essential oils, and requires for congelation a temperature from zero of Fahrenheit to —4°. It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its colour to a deep red, and converts it by the aid of heat into oxalic acid. It combines directly with the mineral alkalies, forming soluble and crystallizable compounds. When long kept it deposites a crystalline *stearoptene.* It is frequently adulterated with fixed oils, and sometimes also with oil of pimento and with copaiba. The oil of cloves should sink in pure water.

Medical Properties and Uses. Its medical effects are similar to those of cloves, and it is used for the same purposes; but its most common employment is as a corrigent of other medicines. Like other powerful irritants it is sometimes effectual in relieving toothach, when introduced into the cavity of a carious tooth. The dose is from two six minims.

OLEUM CINNAMOMI. *U.S.*

Oil of Cinnamon.

"Laurus cinnamomum. Corticis oleum volatile. *The volatile oil of the bark.*" *U.S.*

Off. Syn. CINNAMOMI OLEUM. *Lond.;* LAURUS CINNAMOMUM. Oleum volatile. *Dub.*

Huile de cannelle, *Fr.;* Zimmtöl, *Germ.;* Olio di cannella, *Ital.;* Aceyte de canela, *Span.*

See CINNAMOMUM.

This oil is prepared exclusively in the East. In Ceylon, the cinnamon which was not considered of sufficiently good quality for the East India Company's investment, was formerly appropriated to this purpose. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea-water, and then submitted to distillation. A light and a heavy oil come over with the water, the former of which separates in a few hours, and swims upon the surface, the latter falls to the bottom of the receiver, and continues to be precipitated for ten or twelve days. In future distillations the saturated cinnamon water is employed in connexion with sea-water to macerate the cinnamon. Eighty pounds of the bark freshly prepared yield about two and a half ounces of the lighter oil, and five and a half of the heavier. From the same quantity of cinnamon which has been kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce. An oil is also distilled from the Chinese cinnamon or commercial cassia; but is inferior in flavour to that afforded by the aromatic of Ceylon, and commands a much smaller price. It is called *oil of cassia.* The two are said to be frequently mixed together.

Recently prepared oil of cinnamon is of a light yellow colour, which becomes deeper by age, and ultimately reddish. It has the flavour of cinnamon in a concentrated state. When applied undiluted to the tongue it is excessively hot and pungent. Dr. Duncan states that it sometimes has a peppery taste, which he ascribes to an admixture of the leaves with the bark in the preparation of the oil. It is heavier than water, having the specific gravity 1.035. It congeals below the freezing point of water, and reassumes the liquid form at 41° F. Alcohol completely dissolves it; and as it does not rise in any considerable quantity at the boiling temperature of this liquid, it may be obtained by forming a tincture of cinnamon, and distilling off the menstruum. When very long kept it deposites a *stearoptene* in large, regular, colourless or yellowish crystals. According to Dumas and Péligot, this is a compound of the pure oil with oxygen, and possesses acid properties analogous to those of benzoic acid. They propose to call it cinnamic acid. (*Journ. de Pharm.* xx. 546.) The oil of cinnamon is said to be frequently adulterated with alcohol and fixed oil.

Medical Properties and Uses. It has the cordial and carminative properties of the cinnamon, without its astringency; and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in gastrodynia, flatulent colic, and languor from gastric debility. The dose is one or two minims, and may be most conveniently administered in the form of emulsion.

◆

COCI BUTYRACEÆ OLEUM FIXUM. *Ed.*

Palm Oil.

Huile de palme, *Fr.;* Palmöl, *Germ.;* Aceyte de palma, *Span.*

The *Cocos butyracea* belongs to the class and order *Monœcia Hexandria* and to the family of the Palms. It grows in Brazil, and other parts of South America, and bears a nut, from the kernel of which an oil is obtained by expression, used by the natives in its recent state for dressing food, and when old for burning in lamps. But the Edinburgh College probably errs in ascribing the palm oil of commerce to this tree. That employed in Europe and the United States is thought to be derived chiefly from the *Elais Guiniensis*, a native of the western coast of Africa, and cultivated in the West Indies and South America. This is also a palm, and is placed by systematic writers in the class and order *Diœcia Hexandria*, though stated b others to be really monœcious. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia, and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. The probability is that various species of palms contribute to the supply of this article of commerce.

Palm oil has the consistence of butter, a rich orange-yellow colour, a sweetish taste, and an agreeable odour, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid, and of a whitish colour. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. According to M. Henry, it consists of 31 parts of stearin and 69 of of elaïn.

It is said to be frequently imitated by a mixture of lard and suet, coloured with tumeric, and scented with Florentine orris. The use to which it is chiefly applied, is the manufacture of a toilet soap, which retains the pleasant odour of the oil.

Medical Properties and Uses. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances. W.

* * *

OLEUM LIMONIS. *U.S.*

Oil of Lemons.

"Citrus medica. Fructûs corticis oleum volatile. *The volatile oil of the rind of the fruit.*" *U. S.*

Off. Syn. LIMONUM OLEUM. Corticis exterioris oleum essentiale. *Lond.;* CITRI MEDICÆ OLEUM VOLATILE. Ex cortice fructûs. *Ed.;* CITRUS MEDICA. Fructûs tunicæ exterioris oleum volatile. *Dub.*

Huile de citron, *Fr.;* Cetronenöl, *Germ.;* Olio di limone, *Ital.;* Aceyte de limon, *Span.* See LIMON.

The exterior rind of the lemon abounds in an essential oil, which, as it is contained in distinct cellules, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and preserved in stopped bottles. By a similar process, that delightful perfume, the *essence of bergamot*, is procured from the fruit of the *Citrus bergamia vulgaris* of Risso, or common bergamot tree; and the oil called by the French *huile de cedrat*, from the citron, or fruit of the proper *Citrus medica*, of which the lemon-tree is a variety. All these oils may also be obtained by distillation; but thus procured, they have less of the peculiar flavour of the fruit, and the mode by expression is generally preferred. They are all brought originally from Italy, Portugal, or the South of France.

Properties. The oil of lemons is a very volatile fluid, having the odour of the fruit, and a warm, pungent, aromatic taste. As ordinarily procured it is yellow, and has the specific gravity 0.8517; but by distillation it is rendered colourless; and if three-fifths only are distilled, its sp. gr. is reduced to 0.847, at 71° F. When perfectly pure, it consists exclusively of carbon and hydrogen, and is said to be identical in composition with pure oil of turpentine. In this state it is capable of absorbing almost half its weight of muriatic acid gas, by which it is converted into a crystalline substance, and a yellow oily fuming liquid. The crystals are analogous to the artificial camphor which results from the action of muriatic acid upon the oil of turpentine.

The oil of lemons is often adulterated by the fixed oils and by alcohol, the former of which may be detected by the permanent stain which it imparts to paper, the latter by the milkiness produced by the addition of water.

Medical Properties and Uses. This oil has the stimulant properties of the aromatics; but is almost exclusively used to impart a pleasant flavour to other medicines.

Off. Prep. Alcohol Ammoniatum Aromaticum, *U. S.*, *Ed.*, *Dub.* W.

OLEUM LINI. *U.S.*, *Lond.*, *Dub.*

Flaxseed Oil.

"Linum usitatissimum. Seminum oleum. *The oil of the seeds.*" *U.S.*

Off. Syn. OLEUM LINI USITATISSIMI. *Ed.*

Linseed oil; Huile de lin, *Fr.;* Leinöl, *Germ.;* Olio di lino, *Ital.;* Aceyte de linaza *Span.*

See LINUM.

This oil is obtained by expression from the seeds of the *Linum usitatissimum*, or common flax. In the British Pharmacopœias, directions are given for preparing it by expressing the bruised seeds without heat; but as it is always in this country purchased by the druggists, it has been introduced in the United States Pharmacopœia, into the catalogue of the Materia Medica. In its preparation on a large scale, the seeds are usually roasted before being submitted to pressure, in order to destroy the gummy matter contained in their exterior coating. The oil is thus obtained more free from mucilage, but more acrid than that procured by cold expression. Flaxseed oil is of a yellowish-brown colour, a disagreeable odour, and nauseous taste; is of the sp. gr. 0.932; boils at 600° F.; does not congeal at zero; becomes rancid with facility, and has the property of drying or becoming solid on exposure to the air. On account of its drying property, it is highly useful in painting, and the formation of printers' ink.

Medical Properties and Uses. It is laxative in the dose of a fluidounce, but on account of its disagreeable taste is seldom given internally. It is sometimes added to purgative enemata; but its most ordinary application is externally to burns, usually in combination with lime-water.

Off. Prep. Linimentum Calcis, *U.S.*, *Ed.*, *Dub.* W.

OLEUM MYRISTICÆ. *U.S.*

Oil of Nutmeg.

"Myristica moschata. Nucleorum oleum expressum. *The expressed oil of the kernels.*" *U.S.*

See MYRISTICA.

This substance, usually but erroneously called *oil of mace*, is obtained from nutmegs by bruising them in a heated mortar, and afterwards compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. It has been admitted into the London and Dublin Pharmacopœias, and that of the United States. Nutmegs are said to yield from ten to twelve per cent. of this oil.

The best is imported from the East Indies in stone jars. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow colour more or less mottled, with the odour and taste of nutmeg. It is composed, according to Schrader, of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; a white, pulverulent, inodorous substance, insoluble in these liquids; and a volatile oil, to which it owes its aromatic odour. Eighteen parts are said to furnish one part of volatile oil.

An inferior kind is prepared in Holland, and sometimes found in the shops. It is in hard, shining, square cakes, of a lighter colour than that from the East Indies, with less smell and taste. It is supposed to be prepared from nutmegs, previously deprived of most of their essential oil by distillation.

An artificial preparation is sometimes substituted for the genuine oil. It is made by mixing together various fatty matters, such as suet, palm oil, spermaceti, wax, lard, &c., adding some colouring substance, and giving flavour to the mixture by the volatile oil of nutmeg.

The expressed oil of nutmeg is never used in medicine, except as a gentle external stimulant, and seldom even for this purpose.

Gen. Ch. Corolla four-cleft, with subovate segments. *Drupe* one-seeded. *Willd.*

Olea Europœa. Willd. *Sp. Plant.* i. 44; Woodv. *Med. Bot.* p. 280. t. 98. This valuable tree is usually from fifteen to twenty feet in height, though it sometimes attains a much greater size, particularly in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dull green colour on their upper surface, whitish and almost silvery beneath. The flowers are small, whitish, and disposed in opposite axillary clusters, which are about half as long as the leaves, and accompanied with small, obtuse, hoary bractes. The fruit or olive is a smooth, oval drupe, of a greenish, whitish, or violet colour, with a fleshy pericarp, and a very hard nut of a similar shape. The flowers are not at all fruitful, as clusters containing not less than thirty yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the

Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the South of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are several varieties, distinguished by the form of the leaves, and the shape, colour, and size of the fruit. The variety *longifolia* of Willdenow is said to be the most esteemed.

The leaves and bark of the olive tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. In hot countries a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties; but is not now employed. Analyzed by Pelletier, it was found to contain resinous matter, a small quantity of benzoic acid, and a peculiar principle analogous to gum, which has received the name of *oliville.* But the fruit is by far the most useful product of the tree. In the state in which it is gathered, it is hard and insupportably acrid; but when macerated in water, or an alkaline solution, and afterwards introduced into a solution of common salt, it loses these properties, and becomes a pleasant and highly esteemed article of diet. The pericarp, or fleshy part of the olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in the South of Europe. The oil is obtained by first bruising the olives in a mill, and then submitting them to pressure. The product varies much, according to the state of the fruit and the circumstances of the process. The best oil, called *virgin oil*, is obtained from the fruit picked before it has arrived at perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes, and in the manufacture of the finest soaps, is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case, the pulp is thrown into boiling water, and the oil removed as it rises to the surface. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, &c., is afforded by fruit which has been thrown into heaps and allowed to ferment for several days, or by the *marc* left after the expression of the finer kinds of oil, broken up, exposed to the fermenting process, and again introduced into the press.

Olive oil is imported in glass bottles, or in flasks surrounded by a peculiar kind of net-work made of grass, and usually called Florence flasks. The best comes from the South of France, where most care is exercised in the selection of the fruit.

Properties. The pure oil is an unctuous liquid, of a pale yellow or greenish-yellow colour, with scarcely any smell, and a bland slightly sweetish taste. Its sp. gr. is 0.9153. It begins to congeal at 38° F. At a freezing temperature its stearin becomes solid, and the elaïn, retaining its liquid consistence, may be separated by pressure. or by the agency of cold alcohol, which dissolves it, leaving the concrete principle.

Olive oil when exposed to the air is apt to become rancid, acquiring a disagreeable smell, a sharp taste, a thicker consistence, and a deeper colour; and the change is promoted by heat. It is said to be frequently adulterated with the cheaper fixed oils, especially with that of poppies; but the adulteration may usually be detected by reducing the temperature to the freezing point. As other oils are less readily congealed than the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by M. Poutet, founded on the property possessed by the supernitrate of mercury of solidifying the oil of olives, without a similar influence upon the other oils. Six parts of mercury are dissolved at a low temperature in seven parts and a half of nitric acid of the sp. gr. 1.35; and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it is converted after some hours into a yellow solid mass; if it contain a minute proportion, even so small as a twentieth of poppy oil, the resulting mass is much less firm; and a tenth prevents a greater degree of consistence than oils usually acquire when they concrete by cold.

Medical Properties and Uses. Olive oil is nutritious and mildly laxative, and is occasionally given in cases of irritable intestines, when the patient objects to more disagreeable medicines. Taken into the stomach in large quantities, it serves to involve acrid and poisonous substances, and mitigate their action. It has also been recommended as a remedy for worms, and is a very common ingredient in laxative enemata. Externally applied, it is useful in relaxing the skin, and sheathing irritated surfaces from the action of the air; and is much employed as a vehicle or diluent of more active substances. In the countries bordering on the Mediterranean, it is thought, when smeared over the skin, to afford some protection against the plague; and applied warm, by means of friction over the surface, is said to be useful as a remedy in the early stages of that complaint. But the most extensive use of olive oil is in pharmacy, as a constituent of liniments, ointments, cerates, and plasters.

The dose as a laxative is from one to two fluidounces. W.

Ricinus communis. Willd. *Sp. Plant.* iv. 564; Woodv. *Med. Bot.* p. 624. t. 221. The castor oil plant, or *palma Christi*, as it was formerly called, attains in the East Indies and Africa the character of a tree; and rises sometimes thirty or forty feet in height. In the temperate latitudes of North America and Europe it is an annual plant; though we are informed by M. Achille Richard, that in the South of France, in the vicinity of Nice, on the seacoast, he saw a small wood consisting entirely of this species of Ricinus. The following description applies to the plant as cultivated in cool latitudes. Its general aspect is very peculiar, and not inelegant. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate; peltate or supported upon footstalks inserted into their lower disk; palmate, with seven or nine pointed serrate lobes; smooth on both sides; and of a bluish-green colour. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the male flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, which are united into fasciculi at their base. In the female, the calyx has three or five narrow lanceolate segments; and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish glaucous capsule, with three projecting sides, covered with tough spines, and divided into three cells, each containing one seed, which is expelled by the bursting of the capsule.

This species of Ricinus is a native of the East Indies and Northern Africa; has become naturalized in the West Indies; and is cultivated in various parts of the world, in no country perhaps more largely than in the United States. New Jersey, Virginia, North Carolina, and the States upon the right bank of the Ohio, are the sections in which it is most abundant. The flowers appear in July, and the seeds ripen successively in August and September. The part employed in medicine is the fixed oil extracted from the seeds; and as this is always purchased by the apothecary, it has been very correctly placed, in the United States Pharmacopœia, among the original articles of the Materia Medica. The London College gives a process for its preparation, and therefore directs the seeds in its officinal catalogue.

1. The SEEDS. These are about as large as a small bean, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash colour, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish tubercle, from which an obscure longitudinal ridge proceeds to the opposite extremity, dividing the side upon which it is situated into two flattish surfaces. In its general appearance the seed is thought to resemble the insect called the *tick*, the Latin name of which has been adopted as the generic title of the plant. Its variegated colour depends upon a very thin pellicle, closely investing a hard, brittle, blackish, tasteless, easily separable shell, within which is the kernel, highly oleaginous, of a white colour, and a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts of the seeds Geiger found, exclusive of moisture, 23.82 parts of envelope, and 69.09 of kernel. These 69.09 parts contained 46.19 of fixed oil, 2.40 of gum, 20.00 of starch and lignin, and 0.50 of albumen.

Taken internally the seeds are powerfully cathartic, and often emetic. Two or three are sufficient to purge, and seven or eight act with great violence. This property depends upon an acrid principle, which has by some been thought to exist exclusively in the integuments, by others in the embryo. But it is now satisfactorily ascertained that the integuments are inert; and Guibourt maintains that the principle alluded to pervades the whole kernel, in connexion with the oil. This principle is volatile, and dissipated by the heat of boiling water. By a much greater heat the oil itself becomes altered, and acquires acrid properties.

2. The OIL. This may be extracted from the seeds in three ways; 1. by decoction, 2. by expression, and 3. by the agency of alcohol.

The process by decoction, which is practised in the East and West Indies, consists in bruising the seeds previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. To increase the product it is said that the seeds are sometimes roasted. The oil is thus rendered brownish and acrid; and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated. Hence it happens that the West India oil has generally a brownish colour, an acrid taste, and irritating properties.

The mode by expression is directed by the London College, which simply orders the seeds, previously decorticated, to be bruised, and the oil expressed without heat. But these directions are both redundant and deficient. The removal of the outer covering of the seeds is unnecessary, as it contains no injurious principle; and something more than simple expression is requisite to obtain the oil in a state fit to be kept in the shops. The following, as we have been informed, are the outlines of the process usually employed by those who prepare the oil on a large scale in this country. The seeds having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful screw press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers, supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed; and the process is completed by boiling it with a minute proportion of water, and continuing the application of heat till aqueous vapour ceases to rise, and till a small portion of the liquid taken out in a vial, preserves a perfect transparency when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far, as the oil then acquires a brownish hue, and an acrid, peppery taste, similar to those of the West India medicine. After the completion of the process, the oil is put into barrels, and thus sent into the market. One bushel of good seeds yields five or six quarts, or about twenty-five per cent. of the best oil. If not very carefully prepared, it is apt to deposite a sediment upon standing; and the apothecary frequently finds it necessary to filter it through paper before dispensing it. Perhaps this may be owing to the plan adopted by some of purifying the oil after expression, by merely allowing it to stand for some time, and then drawing off the supernatant liquid. We have been told that the oil in barrels occasionally deposites a copious whitish sediment in cold weather, which it redissolves when the temperature rises. This substance is probably stearin, or an analogous principle. A large proportion of the drug consumed in the eastern section of the Union, is derived by way of New Orleans from Illinois and the neighbouring States, where it is so abundant that it is sometimes used for burning in lamps.

The process for obtaining castor oil by means of alcohol has been practised in France; but the product is said to become rancid more speedily than that procured in the ordinary mode.

Properties. Pure castor oil is a thick, viscid, colourless fluid, with little or no odour, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in the shops it is often tinged with yellow, and has an unpleasant smell; and parcels are sometimes though rarely met with, of a brownish colour, and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque, and it ranks among the drying oils. It is heavier than most of the other fixed oils, from which it differs also in being soluble in all proportions in cold absolute alcohol. Weaker alcohol, of the sp. gr. 0.8425, takes up about three-fifths of its weight. Adulterations with other fixed oils may thus be detected, as the latter are but slightly soluble in this fluid. Such adulterations, however, are not practised in this country. Castor oil is also soluble in sulphuric ether. When distilled it yields, according to MM. Bussy and Lecanu, 1. a colourless, highly odorous volatile oil, which crystallizes by cold, 2. two oleaginous acids, denominated ricinic and oleo-ricinic, which are excessively acrid and nearly concrete, and 3. a solid spongy residue, amounting to two-thirds of the oil employed. Supposing these acids to be developed by heat, we can readily account for the injurious influence of too high a temperature in the preparation of the oil. Alkalies unite with castor oil forming soaps, and determine the formation of the margaric acid, besides the two above mentioned. Its purgative property is ascribed by MM. Bussy and Lecanu to the oil itself, and not to any distinct principle which it may hold in solution. It differs in this respect from the croton oil, though derived from a plant belonging to the same natural family.

Castor oil which is acrid to the taste may be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through paper. On exposure to the air, it is apt to become rancid, and is then unfit for use.

Medical Properties and Uses. Good castor oil is a mild cathartic, speedy in its action, usually operating with little griping or uneasiness, and evacuating the contents of the bowels without much increasing the alvine secretions. Hence it is particularly applicable to cases of constipation from collections of indurated feces, and to those cases in which acrid substances have been swallowed, or acrid secretions have accumulated in the bowels. From its mildness it is also especially adapted to diseases attended with irritation or inflammation of the bowels, as colic, diarrhœa, dysentery, and enteritis. It is habitually resorted to in the cases of pregnant and puerperal women; and is decidedly, as a general rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults, probably because they digest a larger proportion of the oil.

The dose for an adult is about a fluidounce, for an infant from one to three or four fluidrachms. It is sometimes of exceedingly difficult administration, not so much from any peculiarly unpleasant taste, as from the recollection of former nausea, or other uneasiness which it may have produced, and from its clamminess and unpleasant adhesiveness to the mouth. In a few cases the disgust which it excites is utterly unconquerable by any effort of resolution. It is desirable, therefore, to obviate this inconvenience as far as possible by the mode of exhibition. A common method is to give it floating on the surface of mint or cinnamon water; but that which we have found upon the whole the least offensive, is to mix it with a cup of hot sweetened coffee, by which it is rendered more fluid, and its taste considerably disguised. Some take it in wine or spirituous liquors; but these are generally contraindicated in the cases to which the medicine is applicable. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf sugar, and some aromatic water. To this mixture laudanum may be added in cases of intestinal irritation. Castor oil may also be beneficially used as an enema in the quantity of two or three fluidounces mixed with some mucilaginous liquid.

Though apt to become rancid by itself, it loses much of this susceptibility when mixed with lard; and some apothecaries are said to use it as a substitute for olive oil in unguents and cerates. But the slightly irritating properties of even the mildest castor oil, render it inapplicable in those preparations which are intended rather to alleviate irritation than to produce it.

See TEREBINTHINA.

The oil of turpentine is prepared by distillation from our common turpentine, though equally afforded by other varieties. The Dublin College gives the following formula for its preparation. "Take of common turpentine, [*Terebinthina Vulgaris*, Lond.] five pounds; water, four pints. Draw off the oil in a copper alembic." But it is at present never prepared by the apothecary, and in all the other Pharmacopœias is placed in the catalogue of the Materia Medica. The turpentine of the *Pinus palustris* is said to yield about seventeen per cent. of oil; while the common turpentine of Europe affords twenty-four per cent. Large quantities of the oil are distilled in North Carolina for exportation.

Pure oil of turpentine is perfectly limpid and colourless, of a strong, penetrating, peculiar odour, and a hot, pungent, bitterish taste. It is much lighter than water, having the specific gravity 0.86 at 72° F.; is highly volatile and inflammable; boils at a temperature somewhat higher than 300°; is very slightly soluble in water, less soluble in alcohol than most other volatile oils, and readily soluble in sulphuric ether. Boiling alcohol dissolves it with facility, but deposites most of the oil upon cooling. One hundred parts of alcohol of 0.84, dissolve 13.5 parts of the oil at 72°. As found in commerce, it always contains oxygen; but when perfectly pure, it consists exclusively of carbon and hydrogen, and, according to Dumas, is isomeric with the base of camphor. MM. Blanchet and Sell think they have shown that it consists of two distinct isomeric oils, which, by the absorption of oxygen are converted into two distinct resins, corresponding to those found by Unverdorben in colophony, and differing from each other in their solubilities in alcohol. (*Journ. de Pharm.* xx. 226.) On exposure to the air and light, oil of turpentine deposites a white solid matter in acicular crystals, which are without taste or smell, insoluble in cold water, but soluble in ether and alcohol. (*Boissenot, Journ. de Chim. Med.* ii. 143.) White crystals of stearoptene, heavier than water and fusible at 20°, separate from the oil at the temperature of 18° below zero. The oil of turpentine absorbs muriatic acid gas, which forms with it a white crystalline substance which bears a strong resemblance to camphor, and on this account is usually called *artificial camphor.*

Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity. Hence the British Colleges direct a process for its rectification, consisting in distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary, as the recent oil can be obtained at an expense less than that which would be incurred by its redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the portion that has become resinous by the absorption of oxygen. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water.

Medical Properties and Uses. The oil of turpentine is stimulant, diuretic, anthelmintic, in large doses cathartic, and externally rubefacient. When swallowed in moderate quantities it produces a sense of warmth in the stomach, accelerates the circulation, and increases the heat of the skin, without especially affecting the functions of the brain. In small doses frequently repeated it stimulates the kidneys, augmenting the secretion of urine, and often producing, especially if long continued, painful irritation of the urinary passages, amounting sometimes to violent strangury. At the same time it imparts the odour of violets to the urine; and this effect is also produced by its external application, or even by breathing the air of an apartment impregnated with its vapours. In large doses it occasions slight vertigo, or a sense of fulness in the head, sometimes amounting to intoxication, attended frequently with nausea, and succeeded generally, though not always, by speedy and brisk catharsis. When this effect is experienced, the oil is carried out of the bowels, and, no time being allowed for absorption, is less apt to irritate the kidneys and bladder than when taken in small and repeated doses. In some constitutions it produces, even when taken internally, an erythematic eruption on the skin.

The oil of turpentine is employed in numerous diseases. As a stimulant it is useful in low forms of fever, particularly in cases where there is reason to suspect ulcerations of the mucous membranes. There is a particular state of fever usually attended with much danger, in which we have found this remedy uniformly successful. The condition of things alluded to, is one which occurs in the latter stages of typhoid fevers or lingering remittents, in which the tongue having begun to throw off its load of fur in patches, has suddenly ceased to clean itself, and become dry and brownish. The skin is at the same time dry, the bowels torpid and distended with flatus, and the patient sometimes affected with slight delirium. Under the use of small doses of oil of turpentine frequently repeated, the tongue becomes moist, and again coated, the tympanitic state of the bowels disappears, and the patient goes on to recover as in a favourable case of fever. We are disposed to ascribe the effect to a healthy change produced by the oil in the ulcerated surface of the intestines. The medicine has also been recommended as a counter-irritant in yellow and puerperal fevers; and may undoubtedly be given with advantage in the latter stages of these diseases, and in other instances of gastric and enteritic inflammations, which require a resort to stimulation; but the highly favourable reports which have been made of its effects in the early stages of puerperal peritonitis, have probably originated in the confounding of intestinal irritation with that formidable disease. In chronic rheumatism, particularly sciatica and lumbago, the oil has often been given with great benefit. It has also been much extolled as a remedy in neuralgia, in epilepsy and tetanus, in passive hemorrhages, particularly from the bowels, in disordered conditions of the alimentary canal attended with sallow countenance, foul tongue, tumid abdomen, sour or fetid eructation, and general depravation of health, in obstructions of the bowels, in some forms of chronic dysentery and diarrhœa, in obstinate gleets and leucorrhœa, and in chronic nephritic and calculous affections. As a vermifuge also it is very highly esteemed, especially in cases of tænia. It appears, by its poisonous operation, to destroy or debilitate the worm, which losing its hold upon the bowels is then easily discharged. In cases of worms in the stomach it is often very beneficial. The worms, in this instance, are destroyed and digested as any other dead animal matter. In dropsies with feeble action, the oil may sometimes be advantageously given as a diuretic; and in amenorrhœa from torpor of the uterine vessels it is occasionally useful. As a local stimulant or carminative it may be given beneficially in some instances of flatulent colic, and gout in the stomach.

The dose for ordinary purposes is from five to thirty drops, repeated every hour or two in acute, and three or four times a day in chronic diseases. In rheumatism it is recommended by some in the dose of a fluidrachm every four hours. As a remedy for the tape-worm it is given in the quantity of one or two fluidounces, and should be followed by castor oil if it do not operate in three or four hours. In ordinary cases of worms, the dose is much smaller. It may be administered dropped on sugar, or in emulsion with gum Arabic, loaf sugar, and cinnamon or mint water.

In the form of enema it is highly useful in cases of ascarides, obstinate constipation, and distension of the bowels from accumulation of air. No remedy is more effectual in tympanites than injections of the oil of turpentine. From half a fluidounce to two fluidounces may be administered in this way, suspended by the yolk of eggs in a half pint or a pint of water or some mucilaginous fluid.

Externally applied, the oil of turpentine irritates and speedily inflames the skin; and in low forms of fever, with coldness of the surface, is when heated one of the most efficacious rubefacients. It is also used as a liniment in rheumatic and paralytic affections, and various internal inflammations. It should generally, in mild cases, be diluted with olive oil; and in some constitutions, even in this state, produces such violent inflammation of the skin, with extensive eruptions, as to render its external use in any shape improper. Mixed with some mild oil and introduced on cotton into the ear, it is sometimes beneficial in deafness arising from a deficient or unhealthy secretion of wax. Applied to recent burns it is thought by some to be highly useful in allaying the burning pain and promoting a disposition to heal. For this purpose, however, it is usually mixed with the resin cerate, (*basilicon ointment*,) so as to form a liniment capable of being spread upon linen rags. (See *Linimentum Terebinthinæ.*)*

Croton. See CASCARILLA.

Croton Tiglium. Willd. *Sp. Plant.* iv. 543; *Flor. Zeyl.*, 343, Rheede, *Malab.*, ii. p. 61. This species of Croton is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark green colour on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf—the lower being female, the upper male, with straw-coloured petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of continental and insular India. It is pervaded throughout by an acrid purgative principle, which is probably analogous to that found in other plants belonging to the family of the Euphorbiaceæ. Rumphius says that the root is employed in Amboyna in the dose of a few grains as a drastic purge in dropsy; and, according to the same author, the leaves are so acrid that, when chewed and swallowed, they excite painful inflammation in the lips, mouth, throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the portion in which the active principle of the plant is most concentrated. These have been long employed throughout the whole of India as a powerful purgative, and were introduced so early as the year 1630 into Europe, where they were known by the names of *Grana Molucca* and *Grana Tiglia.* But in consequence of their violent effects they passed into neglect, and had ceased to be ranked among medicinal substances, when at a recent period attention was again called to them by the writings of some English physicians in India. They are now imported for the oil which they afford, and which is the only portion of the plant considered officinal.

These seeds are rather larger than a grain of coffee, of an oblong form, rounded at the extremities, with two faces, the external considerably more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes, as in the grain of coffee, their internal surface is flat with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft yellowish-brown epidermis, beneath which the surface is black and smooth; and as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently of a mottled appearance, and sometimes nearly black. The kernel or nucleus is of a yellowish-brown colour, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable, and the acrid property thought to be mitigated. In the dose of one or two grains the kernel purges with great activity.

The oil is obtained by expression from the seeds, in general previously roasted, and deprived of the shell. It may also be separated by decoction in water, or by the action of ether, which dissolves the oil, and leaves it behind when evaporated. According to Dr. Nimmo, the seeds consist of 64 parts of kernel, and 36 of envelope, in the hundred; and the cotyledons yield 60 per cent. of oil.

Properties. Croton oil, as usually found in the shops, is of an orange or reddish-yellow colour, which is owing to the roasting of the seeds previously to expression, and varies more or less according to the greater or less duration of this process. When procured without roasting, it is very nearly colourless. Its smell is faint but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. The oil is wholly soluble in sulphuric ether and oil of turpentine, and partially so in alcohol. Dr. Nimmo ascertained that it consists of two portions, one acrid and purgative, amounting to forty-five per cent., soluble in cold alcohol, and having an acid reaction, the other a mild oleaginous substance like olive oil, soluble in ether and the oil of turpentine, and very slightly soluble in hot alcohol, from which it is precipitated when the liquor cools. The acrid portion consists of a resinous substance, and a very acrid volatile acid, for which Brandes has proposed the name of *crotonic acid.*

It is thought that the croton oil is often adulterated with other fixed oils; but, with the exception of castor oil, they may be detected by their less degree of solubility in alcohol, while the latter is discoverable by its greater solubility. If cold alcohol dissolve less than forty-five per cent. of a suspected sample, the presence of olive oil may be suspected, if more, that of castor oil. It would be difficult, as Dr. Duncan observes, to detect by this test a mixture of these two oils in certain proportions.

We have been told by Dr. Burrough, who was for some time in India, that much of the croton oil there prepared for exportation, is derived from the seeds of a plant wholly different from the Croton Tiglium. Dr. R. E. Griffith of Philadelphia informed us, that from a parcel of these seeds presented to him by Dr. Burrough, he had succeeded in raising a plant which proved to be the Jatropha Curcas, the seeds of which are known by the name of *Barbadoes nuts.* (See *Tapioca.*) The oil is weaker than the genuine croton oil, but is said by Dr. Burrough to be an efficient cathartic in the dose of three or four drops.

Medical Properties and Uses. The substance under consideration is a powerful hydragogue purgative, acting, for the most part, when administered in moderate doses, with ease to the patient; but in large doses apt to excite vomiting and severe griping pain, and capable, if immoderately taken, of producing fatal effects. It acts with very great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also a great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines, as in mania, coma, and the cases of children. A drop placed on the tongue of a person in a comatose state will generally operate. Though long used in India, and known a century ago to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Mr. Conwell. It is chiefly employed in cases of obstinate constipation, in which it often produces the happiest effects after the failure of other medicines; but it may also be advantageously employed in almost all cases in which powerful and speedy purging is demanded. Dropsy, apoplexy, mania, and visceral obstructions, are among the complaints in which it has been particularly recommended. The seeds are said to have been used with great success in India in amenorrhœa. Applied externally, the oil produces inflammation of the skin attended with a pustular eruption, and has been used in this way in rheumatism, gout, neuralgia, glandular and other indolent swellings, and in pulmonary diseases. It should be diluted with three parts of olive oil, soap-liniment, oil of turpentine, or other convenient vehicle, and applied in the way of liniment twice or oftener in the twenty-four hours. Sometimes the insusceptibility of the skin to its influence is such as to require its application undiluted. For further information on this subject the reader is referred to the *Amer. Journ. of Med. Sciences*, xv. 240.

The dose for an adult is one or two drops, and is most conveniently administered in the form of pill. A very safe and convenient plan is to make two drops into four pills with crumb of bread, and give one every hour till it operates. The oil may also be given in emulsion. The form of tincture may be advantageously resorted to when a minute quantity of the medicine is required, as it affords the means of readily dividing the dose. It is said that four drops of the oil applied externally by friction around the umbilicus, will produce a purgative effect. (*Dict. des Drogues.*) W.

Olibanum, the *frankincense* of the ancients, was ascribed by Linnæus to the *Juniperus Lycia*, which is still recognised as its source by the London and Edinburgh Colleges, though the conjecture of Linnæus is now universally admitted to have been incorrect. There appear to be two varieties of olibanum, one derived from the countries bordering on the Red Sea, and taken to Europe by way of the Mediterranean, the other brought directly from Calcutta. The origin of the former remains yet undecided; though some writers refer it to a species of Amyris. The latter has been satisfactorily ascertained to be the product of the *Boswellia serrata* of Roxburgh, a large tree growing in the mountains of India, and found by Mr. Colebrook abundant in the vicinity of Nagpur. The tree belongs to the class and order *Decandria Monogynia*, and to the natural order *Terebintaceæ* of Kunth.

The Arabian or African frankincense is in the form of yellowish tears and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastich, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger smell and taste than the tears, and are often mixed with fragments of bark, and small crystals of carbonate of lime.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous smell, and an acrid, bitterish, and somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame, and a fragrant odour. Triturated with water it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. From 100 parts, Braconnot obtained 8 parts of volatile oil, 56 of resin, 30 of gum, and 5.2 of a glutinous matter insoluble in water or alcohol, with 0.8 loss. Various saline substances were found in its ashes. The oil may be separated by distillation, and resembles that of lemons in colour and smell.

Medical Properties and Uses. Olibanum is stimulant like the other gum-resins; but is now never used internally. It is chiefly employed for fumigations, and enters into the composition of some unofficinal plasters.

Gen. Ch. *Corolla* four-petaled. *Calyx* two-leaved. *Capsule* one-celled, opening by pores under the persistent stigma. *Willd.*

Opium is at present generally believed to be derived exclusively from the *Papaver somniferum*, though every species of poppy is capable of yielding it to a greater or less extent, and some authors have indicated the *Papaver orientale* as its real source. The British and French Pharmacopœias unite with our own in recognising only the first mentioned species.

Papaver somniferum. Willd. *Sp. Plant.* ii. 1147; Woodv. *Med. Bot.* p. 376. t. 138. There are two varieties of this species, which are distinguished by the titles of the white and black poppy, derived from the colour of their seeds. It is the former which is usually described as the proper opium plant.

The *white poppy* is an annual plant, with a round, smooth, erect, glaucous, often branching stem, rising two or three feet in height, and sometimes attaining five or even six feet in favourable situations. The leaves are large, variously lobed and toothed, and alternately disposed upon the stem which they closely embrace. The flowers are terminal, very large, and of a white or silver gray colour, with a tinge of violet at their base. In India they appear in February, in Europe and the United States, not earlier than June, July, or August. The calyx is smooth, and composed of two leaves, which fall when the petals expand. These are usually four in number; but there is a variety in which the flower is double. The germen, which is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, of a rounded shape, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigma, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which, when perfectly ripe, escape through small openings beneath the stigma. The *black poppy* differs from the preceding variety only in the character of the fruit. The capsule is somewhat smaller and more globular, and the seeds are of a brown or blackish colour.

All parts of the poppy are said to contain a white opaque narcotic juice; but the leaves, when analyzed by M. Blondeau, yielded none of those active principles by which opium is characterized. (*Journ. de Pharm.* vii. 214.) It is in the capsule that the juice most abounds, and the virtues of the plant chiefly reside. Hence this part is sometimes employed medicinally in Europe, where it is considered officinal. (See *Papaveris Capsulæ.*) The seeds are wholly destitute of narcotic properties, and are even used as food in many parts of the world. The Romans employed them in the preparation of various dainties. They abound with a bland oil, which may be extracted by expression, and has most of the useful properties of olive oil. It is an article of much importance on the continent of Europe, particularly in France, in the northern departments of which the black poppy is very extensively cultivated for the seed alone. The oil is employed for culinary and pharmaceutic purposes, in painting, and the manufacture of soap, and in other ways as a substitute for olive oil, which is said to be frequently adulterated with it. The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside, before a certain period of its growth; for we are told that in Persia, the young plants which are pulled up to prevent too thick a crop, are used as pot-herbs; and the μήκων of the Greeks, which is believed to be identical with the Papaver somniferum, is said by Hippocrates to be nutritive.

Though generally believed to be a native of Asia, this species of poppy grows wild in the South of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, Egypt, and Asiatic Turkey, for the opium which it affords; and in several parts of Europe, especially in France, not only for this product, but also for the seed and capsules. In this country it is found only in our gardens as an ornamental flower.

The process for procuring opium from the poppy, as practised by the modern inhabitants of India and Persia, according to the accounts of Kerr and of Kœmpfer, is very nearly the same with that described by Dioscorides as employed in his own times, about eighteen hundred years since. As the capsules abound most in the narcotic juice, it is from these that the opium is procured. The operation commences when they are about half grown. When ripe, they afford little or no juice. In the evening, near sunset, two or more longitudinal incisions are made in the capsule, so as not to penetrate its cavity; and are repeated several successive evenings, at the same time, till the whole circumference is scarified. The evening is preferred for the operation, as the night dews are supposed to favour the flow of the juice. The portion which exudes during the night, is scraped off in the morning, and put into suitable vessels, where, by exposure to the sun, and by kneading with the hand, it acquires a sufficient consistence to retain the shape into which it may be moulded. It is then formed into cakes, which are still further dried, then wrapped in leaves, and sent into the market. That opium is obtained by incisions in the capsule, and the collection of the juice which exudes, is evinced not only by the reports of travellers and eye-witnesses, such as Chardin, Kœmpfer, Olivier, and Kerr, but also by the success which has attended the employment of this method in Great Britain and France. Considerable quantities of good opium have been obtained by different individuals in England by scarifying the capsules of the poppy.* Similar success has been met with in France; and the drug obtained by incisions in both countries has been found nearly, if not quite equal to that imported from the East. In the *Dictionnaire des Drogues* it is even stated, that a specimen of opium collected in this way in the vicinity of Provins, gave sixteen per cent. of the active principle, while a good commercial specimen examined by M. Petit, afforded only eight per cent. But results equally favourable have not been generally obtained; and neither in England nor France is it probable that agriculturists will be able to stand a competition, in the culture of this drug, with the low price of labour, united with the favourable influence of climate, in the opium countries of Asia.

Another method of extracting the virtues of the capsules, is to select such as have ceased to yield their juice by exudation, to beat them with a small proportion of water, and inspissate the liquid thus obtained by artificial heat. The ancient Greeks were acquainted with both processes, as appears from the writings of Dioscorides. The term οπιον, derived from οπος, juice, they applied to the substance procured by incision, and answering precisely to the modern opium. The inspissated expressed juice they called μηκωνιον, from μηκων, the name of the plant. Tournefort states that it is the latter preparation which is exported from Turkey as opium, the former being much more valuable, and therefore retained in the country for the use of the great and wealthy. This error has been copied by many writers on the Materia Medica; and till within a comparatively few years, opium was generally believed to be an extract obtained by evaporating either the expressed juice, or a decoction of the capsules. The mistake has been corrected by the experiments of cultivators in England and France, by whom, as before stated, a substance having all the characters of commercial opium, was procured by incisions, while the inspissated expressed juice of the capsules, prepared by M. Deslongchamps, was found not to have more than half the strength.

Commercial History. Commerce is supplied with opium chiefly from Hindostan, Persia, and the Asiatic dominions of Turkey. Large quantities are produced in the Indian provinces of Bahar and Benares, to which the British East India Company, who exercise a monopoly of this branch of agriculture within their dominions, have restricted the cultivation of the poppy. In the interior provinces, which, though under the political control, are not under the immediate civil government of the Company, the natives raise an almost incredible amount of the drug; but little of this enters into maritime commerce, the greater part being consumed in the neighbourhood, or carried still further into the interior. Sir John Malcolm informs us, in his work on Central India, that 350,000 pounds are annually raised in Malwa. The opium produced under the monopoly of the Company, is distributed extensively through continental and insular India, where the Mahometan population employ it habitually in the place of spirituous liquors. Great quantities are also sent to China, into which it finds an easy entrance notwithstanding prohibitory laws. Much was formerly imported by the Company into England, through which a small portion reached our own country; but at present India opium is considered so far inferior to that from Turkey, that it has been almost entirely excluded from our market, and none is brought directly from the East. The great demand for it in the Indian Archipelago and in China, and its consequent high price, have probably contributed more even than its reputed inferiority to this result. Indeed, Ainslie explicitly states that India opium is inferior to none; and it is probable that the specimens from which the description was drawn up that is now current among authors upon the materia medica, were the refuse of the Eastern market. We know that the drug was formerly very much and variously adulterated by the natives. Among the impurities mentioned by authors are the extract of the poppy procured by decoction, the powdered leaves and stems of the plant made into a paste with mucilage, the oil of sesamum, catechu, and even cow-dung. But a more careful superintendence by the officers of the Company is said to have resulted in a great improvement of the India opium; and it is possible that if now imported it might not be found to answer the description usually met with in books.

---

* So early as the year 1796, a premium was awarded by the society for the encouragement of arts, to Mr. Ball, for a specimen of British opium; and in 1823, Messrs. Cowley and Stains collected 196 pounds, which sold for nearly seven dollars a pound, from little more than twelve acres of land. This product, however, was by no means equal to that obtained in Scotland by Mr. John Young. From one acre of ground planted with poppies and potatoes, he procured fifty-six pounds of opium, valued at 450 dollars, while the whole expense was more than repaid by the potatoes, and the oil expressed from the seeds. For papers on the subject of the cultivation of the poppy in England, see *Edin. Philosoph. Journ.* vol. i. p. 258, and the *Quarterly Journal of Science*, vol. iv. p. 69.

Turkey opium is raised chiefly in Anatolia, and is shipped from the port of Smyrna. Much was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection. It was in fact for a long time generally known by the name of *Opium Thebaicum;* and laudanum is still frequently directed in prescriptions as the Tinctura Thebaica. Its cultivation has recently been again introduced into Egypt. The drug is imported into the United States, either directly from the Levant, or indirectly through the Mediterranean ports of France. From the treasury returns for the year 1829, it appears, that the value of opium brought from the Turkish dominions was 92,924 dollars, from France on the Mediterranean, 12,187 dollars, and from all other parts of the world only 2,040 dollars. None was imported from India. Turkey opium comes to us in masses of irregular size and shape, generally more or less flattened, covered with leaves, and with the reddish capsules of some species of *Rumex*, which are said to be absent in the inferior kinds, and may therefore be considered as affording some indication of the purity of the drug. We may account for this circumstance upon the very probable supposition, that the capsules are removed during the operation which the masses sometimes undergo in the hands of the merchants, after leaving those of the cultivators. We are told by the French writers, that extensive frauds are practised at Marseilles in this branch of commerce. The opium brought thither from the Levant is first softened, and then adulterated with various matters, which are incorporated in its substance. To use a strong expression of M. Guibourt, they make the opium over again at Marseilles. Our traders to the Mediterranean would do well to bear this assertion in mind. According to Dr. A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, the extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum Arabic, tragacanth, aloes, even small stones, and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug.*

* Three varieties of Turkey opium are to be met with in commerce, namely, the *Smyrna*, the *Constantinople*, and the *Egyptian*. The following description of these varieties is given by Guibourt in the *Journal de Pharmacie for December* 1831.

Opium is regarded as inferior when it is of a blackish colour; a weak or empyreumatic smell; a sweet or slightly nauseous and bitter taste; a soft, viscid, or greasy consistence; a dull fracture; or an irregular, heterogeneous texture, arising from the intermixture of foreign substances. It should not impart a deep brown colour to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

Properties. Good opium has a peculiar, strong, narcotic odour, and a bitter somewhat acrid taste. When long chewed it excites much irritation in the lips and tongue, and even blisters the mouth of those unaccustomed to its use. Its colour is a reddish-brown or deep fawn; its texture compact and uniform; its specific gravity 1.336. When drawn over paper it leaves an interrupted trace of a light brown colour. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a uniform

"1. *Smyrna opium.* In larger or smaller masses, often deformed and flattened on account of their original softness; covered externally with seeds analogous to those of Rumex; becoming black and dry in the air; of a strong virose odour. This opium is justly most esteemed; but it is proper to observe that it is liable to be mixed with a kind of opium in *balls* or *round masses*, which are hard and of inferior quality."

"2. *Constantinople opium.* In small, flattened, tolerably regular lumps, of a lenticular form, from two inches to two inches and a half in diameter, always covered with a poppy leaf, the middle nerve of which usually marks the middle of the mass. Odour similar to that of the preceding, but weaker. It blackens and dries in the air. Some persons say that this is nothing more than the Smyrna opium, which has been re-manufactured at Constantinople, and often mixed with gum, which injures its quality."

"3. *Egyptian opium.* In round flattened lumps, larger than the preceding, tolerably regular in their form, very clean upon their surface, and appearing to have been covered with a leaf, of which only vestiges remain. This opium is distinguishable from the preceding by its reddish colour, analogous to that of hepatic aloes, by a weaker odour, and by softening instead of drying in the open air. It has, moreover, a shining surface, somewhat adhesive to the fingers."

Four ounces of each of these varieties, well selected, yielded to Guibourt, under the same treatment, the following quantities of morphia not entirely pure:—viz. Smyrna opium 7 dr. 18 gr., Egyptian opium 5 dr. 20 gr., Constantinople opium 3 dr. 55 gr. From this experiment it would appear that the Smyrna is the most powerful, and the Constantinople the most feeble, the Egyptian being intermediate. The last variety has recently been introduced into this country in considerable quantities. As brought to our market, there is reason to believe that it is an article much inferior to Smyrna opium; as a specimen analyzed by Mr. J. Evans, yielded only 3.55 per cent. of pure morphia, while good opium is said to furnish from 9 to 14 per cent. (*Am. Journ. of Pharm.* vii. 6.) We have been informed by a respectable druggist of Philadelphia, that the Constantinople opium is most highly esteemed in our markets, as it is less apt to be mingled with obvious impurities. It will have been observed that Guibourt experimented with good specimens of each variety; and it is probable, that, though the opium which is here sold under the name of Smyrna opium, may from its frequent adulterations be on the whole inferior to the Constantinople, it may, nevertheless, contain pieces of greater strength and value.

Under the name of Persia opium, a variety of this drug exists in the London market, and has occasionally, though rarely, found its way to this country. A specimen sent to M. Guibourt from London is described as being in cylindrical pieces about 4 inches long and half an inch thick, of a reddish colour internally, a uniform texture, and a virose, musty smell. (*Journ. de Pharm.* xxi. 200.) From the report of a trial in the city of New York, published in the Journal of Commerce, it appears, that a parcel of Persia opium imported into that city from London in August last, was in small round balls, and contained only 3 per cent. of morphia. It is highly important that the real value of these commercial varieties of opium should be known to the physician and apothecary, as otherwise, there can be no certainty in relation to the strength of the preparations which may be made from them. In the preparation of laudanum and the other tinctures into which opium enters, it is understood that the drug employed should have the average quality of good Smyrna opium. The inferior kinds should be used only for the extraction of morphia.

shining fracture, and affording when pulverized a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. It is partially soluble in water, alcohol, ether, wine, vinegar, and lemon juice, to all which it imparts a deep brown colour. We are told, that when it is triturated with hot water, five parts out of twelve are dissolved, six suspended, and one remains unaffected. (*A. T. Thomson.*) This is viscid and tenacious, presenting characters strongly analogous to those of caoutchouc. Pelletier states that the proportion of opium taken up by water varies in all specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16. (*Journ. de Pharm. Nov.* 1832.)

Much attention has been devoted to the chemical constitution of opium; and very interesting results have been obtained. It was by their researches into the nature of this substance that chemists were led to the discovery of those vegetable alkaloids, which, as the active principles of the plants in which they are found, have recently attracted so much attention among physicians, and been applied so advantageously to the treatment of disease. To Sertürner, an apothecary at Eimbeck, in Hanover, certainly belongs the credit of having opened this new and most important field of experiment. In the year 1803, M. Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year, Seguin discovered another crystallizable body, which subsequent experience has proved to be the true narcotic principle of opium; but he did not fully investigate its nature, and no immediate practical advantage was derived from his excellent analysis. About the same time, Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained till the year 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance, which, though before discovered both by Seguin and by himself, had been hitherto but vaguely known. To the alkali, in which he correctly conceived the narcotic powers of the opium to reside, he gave the name of *morphium*, which has been subsequently changed to *morphia* by English writers, in order to render it analogous to the titles of the other alkalies. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by the experiments of Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne, and called by him *the salt of opium*, was a principle altogether distinct from the morphia, though supposed to possess very considerable influence over the system. In the belief of its narcotic powers, Robiquet denominated it *narcotin*, a title which it still retains. Several other peculiar principles have since been discovered; though it is difficult to resist the impression that some of them may be the result of the processes to which opium is submitted for their extraction. According to the views of its constitution at present admitted, opium contains 1. morphia; 2. narcotin (narcotina); 3. codein (codeia); 4. meconin; 5. narcein (narceia); 6. meconic acid; 7. a peculiar acid, not yet fully investigated; 8. extractive matter; 9. gum; 10. bassorin; 11. a peculiar resinous body insoluble in ether and containing nitrogen; 12. fixed oil; 13. a substance resembling caoutchouc; 14. an odorous volatile principle; besides a considerable quantity of vegetable remains, and a small proportion of acetic acid, sulphate of lime, sulphate of potassa, alumina, and iron.

Of these constituents *morphia* is by far the most important. Though generally admitted to exist in opium united with meconic acid in the state of meconate, it is also intimately associated with the extractive matter, according to the statement of M. Fauré, who found that the meconic acid of opium was alone insufficient to saturate all the morphia. By this experimenter, the morphia, meconic acid, and extractive, are believed to exist in chemical combination; and hence the meconate cannot be obtained separate from the last mentioned principle. (*Journ. de Pharm.* xv. 571.) Of morphia and the mode of procuring it, and of its salts, we shall treat at large under the head of the pharmaceutic preparations. (See *Morphia.*)

Narcotina is solid, white, tasteless, inodorous, crystallizable in silky flexible needles, usually larger than the crystals of morphia, fusible at a moderate elevation of temperature, insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol which precipitates it upon cooling, and very soluble in ether. The fixed and volatile oils also dissolve it. It exerts no alkaline reaction upon vegetable colours, but is dissolved by most of the acids, and with some of them forms definite compounds, which may be obtained in a separate state, and deserve to be considered as genuine salts. It must, therefore, be ranked among the vegetable alkalies. Robiquet states that he has obtained the sulphate and muriate of narcotina well crystallized. (*Journ. de Pharm.* xvii. 639, and xix. 59.) With acetic acid, however, it does not appear, according to the observation of Pelletier, to form a permanent combination; for though dissolved by cold acetic acid, it is separated by exposing the solution to heat. Though narcotina itself is tasteless, its salts are very bitter, even more so than those of morphia. (*Berzelius.*) They are all soluble in water, and in consequence of the weak neutralizing power of the base, redden litmus paper. Narcotina is precipitated by the alkalies from its solution in the diluted acids. It may be distinguished from morphia by its insipidity and its solubility in ether, by assuming a yellowish instead of a blood-red colour under the action of strong nitric acid, and by not producing, either pure or in the saline state, with the salts of iron, the blue colour which characterizes morphia and its salts. Water extracts it from opium in consequence of the acid which the latter contains, either free or combined with the narcotina; but the diluted acids extract it with greater facility. It is always obtained mixed with morphia in the processes for procuring this principle; and may be separated by the action of sulphuric ether, which dissolves it without affecting the morphia, and yields it upon evaporation. It may also be obtained by digesting opium or its aqueous extract in sulphuric ether, evaporating the ether, treating the residue of the evaporation with boiling water and animal charcoal, filtering, precipitating with ammonia, and purifying the precipitate if necessary, either by solution in hot alcohol which deposites it on cooling, or by solution in muriatic acid, digestion with animal charcoal, filtration, and precipitation by ammonia. In this process the ether takes up, besides the natural salt of narcotina, a fixed oil from the extract, and in addition, caoutchouc and resin from the opium. These are left behind by the water; and the salt of narcotina is decomposed by the ammonia. This at least is the explanation given by Berzelius; but Pelletier and Robiquet maintain that narcotina exists uncombined in opium; and according to the former of these chemists, though a small portion of narcotina, in the above process, is dissolved by water from the ethereal extract, this is owing to the presence of a little free acid; and a much larger proportion of the principle remains in the extract undissolved. (*Journ. de Pharm.*) Another mode of procuring narcotina is to treat opium, which has been exhausted by previous maceration in water, with acetic acid, filtering the solution, precipitating by an alkali, washing the precipitate with water, and purifying it by means of boiling alcohol, as in the former instance. Should it still be impure, the solution in alcohol and crystallization may be repeated.

Different opinions have been advanced relative to the action of narcotina on the system. Derosne believed it to be the active principle of opium; though upon experimenting with it, he obtained effects but little stronger than those produced by an equal dose of opium itself. Magendie found it to exercise a powerful influence upon the system of dogs. One grain dissolved in oil was sufficient to throw the animal into a state of stupor, which terminated in death in the course of twenty-four hours. This stupor was wholly different from the composed sleep produced by morphia and its preparations. He inferred, that while the latter principle exercises the remedial, anodyne, and soporific virtues of opium, the injurious excitant operation of the medicine is ascribable to the narcotina. Both Derosne and Magendie found its unpleasant effects to be modified or prevented by its conjunction with acetic acid. According to Magendie, twenty-four grains, dissolved in vinegar, may be given to a dog without destroying life. M. Baily prescribed it in the dose of sixty grains, both in the solid state and dissolved in muriatic acid, without observing from it any sensible effect. In the same state, Orfila found that it might be taken by man in very large doses with impunity; and thirty grains of it dissolved in acetic acid, produced no effect upon several patients to whom it was administered. Upon dogs, he informs us, that it is without action when dissolved in nitric or muriatic acid; but held in solution by acetic or sulphuric acid, or by olive oil, thirty or forty grains of it were sufficient to produce fatal effects. A singular circumstance noticed by the same experimenter is, that the solution in acetic or sulphuric acid occasioned violent excitement; while the contrary condition uniformly resulted from the use of that in olive oil. On the whole, we may conclude that narcotina is nearly inoperative upon the human system, either in the solid form or dissolved in acids; and that the narcotic effects which have been attributed to it, have probably arisen from the employment of a preparation not entirely freed from other principles contained in the opium. It may be considered as certain, that substances differing in some respects have been obtained and described under the name of narcotina; for the most skilful analytical chemists of the age have given statements of its composition wholly irreconcilable with each other, and to be accounted for only upon the supposition that they did not experiment on precisely the same body. Thus Pelletier and Dumas found 7.21 per cent. of nitrogen, and Liebig only 2.51 per cent. Perhaps the discovery of the new principles in opium may throw some light on this subject. Narcotina is composed, according to an analysis conducted with great care by Pelletier, of 65,16 parts of carbon, 4.31 of nitrogen, 5.45 of hydrogen, and 25.08 of oxygen. (*Journ. de Pharm.* xviii. 624.) According to Robiquet, its muriate consists of 4.585 parts of narcotina, and 0.409 parts of dry acid. (*Ibid.* xix. 63.)

Codeia was discovered in 1832 by Robiquet in the muriate of morphia prepared according to the process of Gregory. It exists in opium combined like morphia with meconic acid, and is extracted along with that alkali in the preparation of the muriate. (See *Morphia.*) When the solution of the mixed muriates of morphia and codeia is treated with ammonia, the former alkali is precipitated, and the codeia, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them and yields the codeia in colourless crystals by spontaneous evaporation. This alkaline product melts at 300°

without decomposition. It is soluble in water, which takes up 1.26 per cent. at 60°, 3.7 at 110°, and 5.9 at 212°. It is soluble also in alcohol and ether, but is insoluble in alkaline solutions. It combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphia. According to Robiquet, 1 part of muriatic acid is saturated by 7.837 of codeia, and by 7.88 of morphia. It is distinguishable, however, from the latter principle, by the different form of its crystals, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, by affording a copious precipitate with tincture of galls, and by not assuming a red colour with nitric acid, nor a blue one with the persalts of iron. (*Journ. de Pharm.* xix. 91.) Its crystals contain about 6 per cent. of water, which is driven off at 212°. Mr. Gregory tried the effects of *nitrate of codeia* upon himself and several of his pupils, and found that, in a dose of three grains or less, it produced no obvious effect, but in the quantity of from four to six grains, accelerated the pulse, occasioned a sense of heat in the head and face, and gave rise to an agreeable excitement of the spirits like that resulting from intoxicating drinks, which was attended with a sense of itching upon the skin, and after lasting for several hours, was followed by an unpleasant depression, with nausea and sometimes vomiting, No tendency to sleep was observed, except in the state of depression. In two or three cases the medicine produced a slight purgative effect; but in others it appeared to exercise no peculiar influence on the bowels. M. Barbier of Amiens administered codeia *uncombined* in numerous cases, and observed that, in the dose of one or two grains, it acted on the nervous system, and appeared to be directed especially to the nervous plexus of the great sympathetic, as it relieved painful affections having their origin apparently in disorders of this plexus, while it exerted no influence over pains of the back and extremities supplied by nerves from the spinal marrow. He did not find it to affect the circulation, to disturb digestion, or to produce constipation. In sufficient quantity, it induced sleep, without occasioning those marks of cerebral congestion induced by opium. On the whole, there can be no doubt that this principle has a decided action on the animal economy, and is among those upon which opium depends for its peculiar powers.

Meconin, the existence of which was announced in 1832 by M. Couerbe, is identical with a substance discovered several years previously by M. Dublanc, jun., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in ether, alcohol, and the essential oils, fusible at 195°, volatilizable without change, wholly destitute of nitrogen in its composition, and possessed of a degree of acrimony which favours the supposition that it may not be without action upon the system. It is neither acid nor alkaline. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the precipitate with water until the latter nearly ceases to acquire colour, mixing the watery fluids, evaporating them to the consistence of molasses, setting them aside for fifteen days or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquor while hot, and subjecting the crystals which form upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation. (*Journ. de Pharm., Decemb.* 1832.)

Narceia, discovered by Pelletier in 1832, is white, in silky acicular crystals, inodorous, of a slightly bitter taste, fusible at 197° F., soluble in 375 parts of cold and 230 of boiling water, soluble also in alcohol, and insoluble in ether. It is rendered blue by the action of mineral acids so far diluted as not to decompose it; but does not, like morphia, become blue by the action of the salts of iron, nor red by that of nitric acid. It combines with but does not neutralize the acids, in this respect corresponding with narcotina. Its constituents are carbon, hydrogen, nitrogen, and oxygen. Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphia by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta water, separated the excess of baryta by carbonate of ammonia, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, upon cooling, deposited crystals of *narceia*, which were easily purified by repeated solution and crystallization. When mixed with meconin, which often crystallizes with it, the latter may be separated by the agency of ether. It may be doubted whether these two substances really exist in opium, or are formed by the mutual reaction of other principles, during the process by which they are procured.

Meconic acid is white, solid, crystallizable, fusible at about 220° F., volatilizable without change, of a sour taste followed by bitterness, soluble in water and alcohol, with the property of reddening vegetable blues, and of striking a blood-red colour with the salts of iron. This last property is characteristic. The following is Robiquet's process for obtaining the acid. An infusion of opium is boiled, for fifteen or twenty minutes, with a quantity of caustic magnesia equal to about two per cent. of the opium employed, and then filtered; the matter deposited on the filter containing meconate of magnesia, morphia, &c., is washed with cold distilled water, and having been treated first with diluted alcohol, and afterwards with concentrated alcohol, to separate the colouring matter and morphia, is submitted to the action of very weak sulphuric acid with heat; the acid liquor is precipitated with solution of muriate of baryta, which throws down the meconate and sulphate of baryta, contaminated with colouring matter; the precipitate is washed and macerated with weak sulphuric acid, to separate the baryta from the meconic acid which is now dissolved; the liquor is filtered and concentrated by evaporation; and lastly the acid, which separates in the form of a reddish-yellow mass, is taken from the mother waters, washed with a small quantity of cold water, dried, and freed from the colouring matter by sublimation. Meconic acid is not used separately in medicine; but its natural relation with morphia requires that it should be understood.

The remarks which have hitherto been made on the physical properties and composition of opium, have reference to the variety procured from Turkey. The *India* opium, according to Dr. A. T. Thomson, is distinguished by the following characters. It is in round masses, covered with the petals of the poppy in successive layers, to the thickness of nearly one-fourth of an inch. It has a strong empyreumatic smell, with little of the peculiar heavy odour of the Turkey opium. Its taste is more bitter, and equally nauseous, but less acrid. Its colour is blacker, and its texture, though as tenacious, is less plastic. It is more friable, and when triturated with water, is wholly suspended or dissolved, leaving none of that plastic residue which is afforded by the other variety. It yielded to Dr. Thomson more narcotina than the Turkey opium, but only about one-third the quantity of morphia. It appears to us highly probable, from the characters of India opium detailed by Dr. Thomson, that the specimens he examined were, in fact, rather the extract of the poppy heads obtained by decoction, than the inspissated juice; for we cannot conceive that there should be so essential a difference between the genuine opium of India and that of Turkey, while the latter agrees almost precisely with that produced in England and France. The absence of the plastic principle analogous to caoutchouc, is a strong evidence in favour of this opinion; for it is obvious that water would not extract this from the capsules, while it is hardly probable that the juice is destitute of it. Besides, the strength of India opium, as above described, is very nearly the same with that of the extract of the capsules prepared in France. The best opium used in India is undoubtedly a very different substance; and we have been thus particular, in order that, should any of it reach us, we might be prepared to value it by its intrinsic merits, not by the reputation which it has acquired in books, and which is maintained by the habit among authors of copying each other's statements without due examination. Indeed, we find it stated in the *Journal de Pharmacie* for May, 1835, that a sample of India opium possessed by Dr. Christison of Edinburgh, yielded to him nine and a half per cent. of muriate of morphia, which very nearly equals the product of good Turkey opium.

Incompatibles. All the substances which produce precipitates with opium, do not necessarily affect its medical virtues; but the *alkalies*, and all vegetable infusions containing tannin and gallic acid, are strictly incompatible; the former separating and precipitating the active principle, the latter forming with it an insoluble compound.

The proportion of morphia which any particular specimen of opium will furnish, may be considered as the best test of its value, except that of actual trial upon the system. Good opium should yield ten or twelve per cent. of the impure morphia precipitated from the infusion by ammonia with alcohol according to the process of the United States Pharmacopœia. (See *Morphia.*)

The London College judiciously directs that opium, before being used, be carefully separated from all foreign substances, especially those which are external. The College also directs that it should be kept in two states —*soft*, fit to form pills; and *hard*, by drying it with the aid of a water-bath, so that it may be pulverized.

Medical Properties and Uses. Opium is a stimulant narcotic. Taken by a healthy person, in a moderate dose, it increases the force, fulness, and frequency of the pulse, augments the temperature of the skin, invigorates the muscular system, quickens the senses, animates the spirits, and gives new energy to the intellectual faculties. Its operation, while thus extending to all parts of the system, is directed with peculiar force to the brain, the functions of which it excites sometimes even to intoxication or delirium. In a short time this excitation subsides; a calmness of the corporeal actions, and a delightful placidity of mind succeed; and the individual, insensible to painful impressions, forgetting all sources of care and anxiety, submits himself to a current of undefined and unconnected, but pleasing fancies; and is conscious of no other feeling than that of a quiet and vague enjoyment. At the end of half an hour or an hour from the administration of the narcotic, all consciousness is lost in sleep. The soporific effect, after having continued for eight or ten hours, goes off, and is generally succeeded by more or less nausea, headach, tremors, and other symptoms of diminished or irregular nervous action, which soon yield to the recuperative energies of the system; and unless the dose be frequently repeated, and the powers of nature worn out by over-excitement, no injurious consequences ultimately result. Such is the obvious operation of opium when moderately taken; but other effects, very important in a remedial point of view, are also experienced. All the secretions, with the exception of that from the skin, are either suspended or diminished; the peristaltic motion of the bowels is lessened; pain and inordinate muscular contraction, if present, are allayed; and general nervous irritation is composed, if not entirely relieved.

When large doses are taken, the period of excitement and exhilaration is shorter; the soporific and anodyne effects are more intense and of longer duration; and the succeeding symptoms of debility are more obvious and alarming.

In quantities sufficient to destroy life, opium scarcely produces any sensible increase of the general powers of the system, but almost immediately reduces the frequency, though not the force of the pulse, diminishes muscular strength, and brings on languor and drowsiness, which soon eventuate in a deep apoplectic sleep. A stertorous respiration; a dark suffusion of the countenance; a full, slow, and labouring pulse; an almost total insensibility to external impressions; and—when a moment of consciousness has been obtained by violent agitation, or powerfully irritating applications—a confused state of intellect, and an irresistible disposition to sink back into comatose sleep, are symptoms which, for the first few hours, attend the operation of the poison. Though not signs of an elevated condition of the bodily powers, neither do they imply a state of pure, unmixed debility. The pulse is, indeed, slow; but it is often so full, and so powerful in its beat, that the practitioner feels himself obliged to use the lancet. In the space, however, of a few hours, varying according to the quantity of the narcotic taken, and the powers of the patient's constitution, a condition of genuine debility ensues; and this condition will be hastened in point of time, though it will be more under the control of remedies, if the opium be removed artificially from the stomach. Called to an individual labouring under the influence of a fatal dose of opium, at a period from six to eight hours after it has been swallowed, the practitioner will generally find him with a cool, clammy skin; cold extremities; a pallid countenance; a feeble, thread-like, scarcely perceptible pulse; a slow, interrupted, almost gasping respiration; and a torpor little short of absolute, deathlike insensibility. With such symptoms, the patient is usually beyond the reach of assistance: the poison has worked its fatal effects; and the last convulsive struggle of the system may be every moment expected.

No appearances are revealed by the dissection of those who have died of the immediate effects of opium, which can be considered as affording satisfactory evidence of its mode of operation. The redness occasionally observed in the mucous membrane of the stomach, is by no means constantly present, and is ascribable rather to the irritating substances prescribed as remedies, or to the spirituous vehicle in which the poison has been swallowed, than to the action of the poison itself. Such at least is the inference drawn by Nysten from his experiments and observations; and Orfila states that the stomachs of dogs which he had killed by opium internally administered, did not present the slightest vestige of inflammation. The force of the medicine is directed to the cerebral and nervous functions; and death is produced by a suspension of respiration arising from the want of due influence from the brain. The section of the par vagum on both sides has not been found to prevent or retard the death of animals to which large doses of opium have been given, nor even materially to modify its narcotic effects.*

---

* Nysten, quoted by Orfila.

It would seem, therefore, that the active principle is conveyed into the circulation, and operates upon the brain, and probably upon the nervous system at large, by immediate contact with their interior structure. It is an error to attribute the anodyne, sedative, and soporific effects of the medicine to the previous excitement. They are, as much as this very excitement, the direct results of its action upon the brain. It is in the state of exhaustion and collapse which ensue after the peculiar influence of the opium has ceased, that we are to look for an illustration of that principle of the system, by which any great exaltation of its energies above the natural standard is followed by a corresponding depression. We may be permitted to advance the conjecture, that the excitement which almost immediately supervenes upon the internal use of opium, is produced by means of nervous communication; while the succeeding narcotic effects are attributable to its absorption and entrance into the circulation; and the prostration of all the powers of the system which ultimately takes place, is a necessary consequence of the agitation into which the various organs have been thrown.

On some individuals opium produces very peculiar effects, totally differing from the ordinary results of its operation. In very small quantities it occasionally gives rise to excessive sickness and vomiting, and even spasm of the stomach; in other cases it produces restlessness, headach, and delirium; and we have known it, even in large doses, to occasion obstinate wakefulness. The headach, want of appetite, tremors, &c., which usually follow, in a slight degree, its narcotic operation, are uniformly experienced by some individuals to such an extent, as to render the use of the medicine very inconvenient. It is possible that some of these disagreeable effects may arise not from the meconate of morphia contained in the opium, but from some other of its ingredients; and those which do result from the meconate, may not be produced by other salts of morphia. It has, in fact, been found that the operation of opium may often be favourably modified by changing the state of combination in which its active principle naturally exists. Dissolved in vinegar or lemon juice, it had been known to act in some instances more pleasantly and effectually than in substance, or in the state of tincture, long before physicians had learned to explain the phenomenon by referring it to the production of an acetate or citrate of morphia. When upon the subject of morphia, we shall take occasion to treat of the medical properties of this principle in its various combinations.

An occasional effect of opium, which has not yet been alluded to, is a disagreeable itching or sense of pricking in the skin which is sometimes attended with a species of miliary eruption. We have found the effect to result equally from all the preparations of this narcotic.

The general operation of opium may be obtained by injecting it into the rectum, or applying it to the surface of the body, especially upon a part denuded of the cuticle. It has appeared to us, when thus applied, to produce less general excitement, in proportion to its other effects, than when administered by the mouth; but we do not make the statement with entire confidence. It is said that when introduced into the cellular membrane, it acts with great energy; and when thrown into the cavity of the peritoneum speedily produces convulsions and death. Injected into the cavity of the heart, it impairs, or altogether destroys the powers of this organ.

The local effects of opium are of a similar character with those which follow its general operation. An increased action of the part is first observable; then a diminution of its sensibility and contractility; and the latter effect is more speedy, more intense, and of longer continuance, the larger the quantity in which the narcotic is applied.

In all parts of the world, opium is habitually employed by many with a view to its exhilarating and anodyne influence. This is particularly the case among the Mahomedans and Hindoos, who find in this narcotic the most pleasing substitute for those alcoholic drinks which are interdicted by the precepts of their religion. In India, Persia, and Turkey, it is consumed in immense quantities; and many nations of the East smoke opium as those of the West smoke tobacco. This is not the place to speak of the fearful and blasting effects of such a practice upon both the intellectual and bodily faculties.

The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates; and it was probably employed before his time. It is at present more frequently prescribed than perhaps any other article of the materia medica. Its extensive applicability to the cure of disease, will be rendered evident by a view of the indications which it is calculated to fulfil. 1. It is excitant in its primary action. In low or typhoid complaints, requiring a supporting treatment, it exalts the actions of the arterial and nervous systems, and in moderate doses frequently repeated, may be employed with advantage in conjunction or alternation with other stimulants. 2. It relieves pain more speedily and effectually than any other medicine with which we are acquainted. If possessed of no other property than this, it would be entitled to high consideration. Not to mention cancer, and those other incurable affections, which, if not alleviated by opium, would render the remainder of life a scene of continued torture; we have numerous instances of painful diseases which are not only temporarily, but entirely cured by the remedy; and there is scarcely a complaint in the catalogue of human ailments, in the treatment of which it is not occasionally demanded for the relief of suffering, which, if allowed to continue, might aggravate the disorder, and protract, if not prevent a cure. 3. Another very important indication, which, beyond any other narcotic, it is capable of fulfilling, is the production of sleep. For this purpose it is given in a great variety of diseases—whenever, in fact, morbid vigilance exists, not dependent on acute inflammation of the brain. Among the complaints in which it proves most serviceable in this way, is the delirium tremens, or mania of drunkards, in which it is frequently sufficient of itself to effect a cure. Opium produces sleep in two ways; first, by its direct operation on the brain, secondly, by allaying that morbid nervous irritation upon which wakefulness generally depends. In the latter case it may frequently be advantageously combined with camphor or Hoffman's anodyne. 4. Opium is powerfully antispasmodic. No medicine is so efficient in relaxing spasm, and in controlling those irregular muscular movements which depend on unhealthy nervous action. Hence its great importance as a remedy in tetanus; colic; spasm of the stomach attending gout, dyspepsia, and cholera; spasm of the ureters in nephritis, and of the biliary ducts in the passage of calculi; and in various convulsive affections. 5. Probably dependent upon a similar influence over the nervous system, is the property which it possesses of allaying general and local irritations, whether exhibited in the nerves or blood-vessels, provided the action do not amount to positive inflammation; and even in this case it is sometimes prescribed with advantage. Hence its use in composing restlessness, quieting cough, and relieving nausea, tenesmus, and strangury. 6. In suppressing morbid discharges, it answers another indication which fits it for the treatment of a long list of diseases. This effect it is, perhaps, enabled to produce by diminishing the nervous energy upon which secretion and muscular motion depend. Upon this principle it is useful in diarrhœa, when the complaint consists merely in increased secretion into the bowels, without high action or organic derangement; in consumption, chronic catarrh, humoral asthma, and other cases of morbidly increased expectoration; in diabetes; and in certain forms of hemorrhage, particularly that from the uterus, in combination with other remedies. 7. It remains to mention one other indication—that of producing perspiration—in fulfilling which opium, conjoined with small doses of emetic medicines, is pre-eminent. No diaphoretic is so powerful as a combination of opium and ipecacuanha; and none is so extensively employed. We shall speak more fully of this application of the remedy under the head of *Pulvis Ipecacuanhæ et Opii.* It is here sufficient to say, that its beneficial effects are especially experienced in rheumatism, the bowel affections, and certain forms of pulmonary disease.

From this great diversity of properties, and the frequent occurrence of those morbid conditions in which opium affords relief, it is often prescribed in the same disease to meet numerous indications. Thus, in idiopathic fevers, we frequently meet with morbid vigilance and great nervous irritation, combined with a low condition of the system. In typhous pneumonia, there is the same depression of the vital powers, combined with severe neuralgic pains, and much nervous irritation. In diarrhœa, besides the indications presented by the spasmodic pain and increased discharge, there is a strong call for the diaphoretic operation of the opium. It is unnecessary to multiply instances. There is hardly a complaint which does not occasionlly present a complication of symptoms demanding the use of this remedy.

But a medicine possessed of such extensive powers may do much injury if improperly directed; and conditions of the system frequently occur, in which, though some one of the symptoms calls for its use, others, on the contrary, are incompatible with it. Thus, opium is contra-indicated by a high state of inflammatory excitement, which should be reduced before we can with propriety venture upon its employment; and when there is any doubt as to the sufficiency of the reduction, the opium should be given in combination with tartarized antimony or ipecacuanha, which modify its stimulant operation, and give it a more decided tendency to the skin. It is also contra-indicated by strong determination of blood to the head, and whenever constipation of the bowels is particularly to be avoided. When, however, the constipation depends upon intestinal spasm, as in colic, it is sometimes relieved by the antispasmodic action of the opium; and the binding effects of the medicine may generally be counteracted by the use of laxatives.

Opium is usually administered in substance or in tincture. In the former state it is given in the shape of pill, which, as a general rule, should be formed out of powdered opium, as it is thus more readily dissolved in the liquors of the stomach, and therefore operates more speedily and effectually, than when made, as it sometimes is, immediately from the plastic mass. There is no medicine of which the dose is more variable, according to the habits of the patient, the nature of his complaint, or the purpose to be effected. While in catarrh and diarrhœa, we often prescribe not more than one-fourth or one-third of a grain; in tetanus and some other nervous affections, it has been administered, without abating the violence of the symptoms, in the enormous quantity of two drachms in twenty-four hours; and in a case of cancer of the uterus, under the care of the late Drs. Monges and La Roche of this city, the quantity is stated to have been gradually increased, till the amount taken during one day, either in the shape of tincture or in substance, was equivalent to more than three ounces. The medium dose, in ordinary cases of disease, to produce the anodyne and soporific effects of the medicine, is one grain.

Opium may often be applied with great advantage by the rectum. In this way it operates most advantageously in cases of obstinate vomiting, of painful nephritic and uterine affections, of strangury from blisters, and of dysenteric tenesmus. It may be employed as a suppository, or in the form of enema made with laudanum and a small quantity of viscid liquid, as flaxseed tea, mucilage of gum Arabic, or starch prepared with hot water. The quantity, as a general rule, may be three times that administered by the mouth; but the relative susceptibility of the stomach and rectum in different persons, is not always the same; and the effects produced by the narcotic given by injection, are sometimes much greater than was anticipated. The practitioner, moreover, should take into consideration the previous habits of the patient. It is possible that, in an individual who has long been accustomed to take opium internally, and whose stomach will receive large doses with impunity, the rectum may not have lost, in a proportionate degree, its absorbing power or susceptibility; and that serious consequences might result by adhering, in such a case, to the general rule, as to the relative quantity to be given in the way of enema or suppository.

In some one of its liquid preparations, opium is often used externally as an addition to collyria in ophthalmia, to injections in gonorrhœa, and lotions in various complaints of the skin, and external pains, as those of gout and rheumatism. It is also used as a local anodyne in the state of powder, made into a plaster or cataplasm.

When opium has been taken in an overdose, the only effectual mode of relief is immediately to evacuate the stomach, either by means of the stomach-pump, or when this is not attainable, by the more active emetics, such as tartarized antimony, sulphate of zinc, or sulphate of copper, conjoined with ipecacuanha. Emetics are preferable to the stomach-pump, when opium has been swallowed in substance, as the capacity of the tube is insufficient to admit of the passage of the masses in which the poison is sometimes taken. The operation of the emetic should be promoted by a very free use of warm drinks, by irritating the fauces with a feather, by keeping the patient in motion, and, if the insusceptibility to the action of the remedy is very great, by dashing cold water upon the head and shoulders, thus counteracting, for a moment, the narcotic influence of the opium upon the brain, and enabling this organ to receive and transmit the necessary impressions. After the evacuation of the poison, the chief indication is to obviate the debility which generally supervenes, and which, in cases where the quantity of the narcotic has been large, or has remained long in the stomach, is sometimes alarming and even fatal. For this purpose, the carbonate of ammonia or the aromatic spirit of ammonia, with wine whey, may be employed internally, and sinapisms and stimulant frictions applied to the surface. The practitioner should not despair even if called at the last moment. The stomach-tube may be applied at any period; and it is possible that even without an evacuation of the stomach, a little assistance may enable the system to resist successfnlly the prostrating influence of the poison, if not taken in an overwhelming dose. Should all other measures fail, resort may be had to artificial respiration, by which the functions of the lungs and heart may possibly be sustained till the brain has struggled through its conflict with the narcotic, and is enabled to resume its natural action. Brodie has demonstrated that death from many of the narcotics results from a suspension of the cerebral influence necessary to sustain the respiratory function, and that the heart ceases to act in consequence of the cessation of respiration. If this can be restored artificially before the contractions of the heart have entirely ceased, the circulation may continue, and life be supported for a time without the interference of the brain, which now receives a supply of arterial blood, and is thus better enabled to rise above the repressing action of the opium. As this narcotic does not produce a structural derangement, but operates chiefly upon the nervous power, a favourable result is more likely to be experienced than in cases of poisoning from some other articles of the same class. A case is on record, in which a child, apparently in the very last stage, was saved by a resort to artificial respiration.*

It is often desirable to ascertain the presence of opium in any suspected mixture. A test proposed by Dr. Hare, Professor of Chemistry in the University of Pennsylvania, though not to be relied on with absolute certainty, may be advantageously resorted to as an auxiliary to other means. It is founded on the fact that meconic acid forms a red salt with the peroxide of iron. Dr. Hare precipitates the meconate of lead by the addition of a few drops of a solution of the acetate of lead to the suspected liquid; applies to the precipitated meconate by means of a dropping-tube, about thirty drops of sulphuric acid, by which the meconic acid is separated; and finally adds in the same way a solution of the red sulphate of iron, which gives the striking red colour of the permeconate of that metal. By this mode a drop of laudanum may be detected in six fluidounces of water.† Orfila states that this test may be much simplified. All that is necessary is to separate the meconic acid from its native combination, and then combine it with the peroxide of iron. This may be accomplished by first adding sulphuric acid, and afterwards the ferruginous persulphate. Even the persulphate of iron alone will, according to Orfila, strike a red colour with a solution of opium, owing to its excess of acid.‡ It is obvious that the meconic acid only is detected; but as this has not been found in any other substance than opium, the presumptive evidence afforded by the test is strong.

Gen. Ch. *Fruit* elliptical, compressed, flat. *Petals* involute, entire. *Willd.*

Pastinaca Opopanax. Willd. *Sp. Plant.* i. 1466; Woodv. *Med. Bot.* p. 122. t. 47. This species of parsnip, usually called *rough parsnip*, has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches.

The plant is a native of the Levant, and grows wild in the South of France, Italy, and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice, as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he has never met with it in any Indian medicine bazaar.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow colour, speckled with white on the outside, paler within, and when broken exhibiting white pieces intermingled with the mass. Its odour is strong, peculiar, and unpleasant; its taste bitter and acrid. Its sp. gr. is 1.622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were from 100 parts, 33.4 of gum, 42 of resin, 4.2 of starch, 1.6 of extractive, 0.3 of wax, 2.8 of malic acid, 9.8 of lignin, 5,9 of volatile oil and loss, with traces of caoutchouc. Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky solution, which deposites resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavour; but only a very minute proportion of oil can be obtained in a separate state.

Medical Properties and Uses. Opopanax was formerly employed as an antispasmodic and deobstruent, in hypocondriasis, hysteria, asthma, and chronic visceral affections, and as an emmenagogue in suppression of the menses; but it is now generally regarded as a medicine of very feeble powers, and in this country is scarcely ever used. Its dose is from ten to thirty grains.

ORIGANUM. *U.S.*

Origanum.

"Origanum vulgare. Herba. *The herb.*" *U. S.*

Off. Syn. ORIGANUM. Origanum vulgare. *Lond.*; ORIGANUM VULGARE. *Dub.*

Origan, *Fr.;* Gemeiner Dosten, Wohlgemuth, *Germ.;* Origano, *Ital.;* Oregano, *Span.*

ORIGANUM. *Sex. Syst.* Didynamia Gymnospermia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Strobile* four-cornered, spiked, collecting the calyces. *Corolla* with the upper lip erect and flat, the lower three-parted, with the segments equal. *Willd.*

Origanum vulgare. Willd. *Sp. Plant.* iii. 135; Woodv. *Med. Bot.* p. 344. t. 123. Origanum or *common marjoram* is a perennial herb, with erect, purplish, downy, four-sided, trichotomous stems, which rise about eighteen inches high, and bear opposite, ovate, entire, somewhat hairy leaves, of a deep yellowish-green colour. The flowers are numerous, of a pinkish-purple or rose colour, disposed in roundish, panicled spikes, and accompanied with ovate reddish bractes, longer than the calyx. This is tubular, and five-toothed, with nearly equal segments. The corolla is funnel-shaped. with the upper lip erect, bifid, and obtuse, the lower trifid, blunt, and spreading. The anthers are double, the stigma bifid and reflexed.

The plant is a native of Europe and America. In this country it grows along the road sides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. The oil, which is the part chiefly employed, is imported from Europe.

Properties. Common marjoram has a peculiar agreeable aromatic odour, and a warm, pungent taste. These properties it owes to a volatile oil, which may be separated by distillation. (See *Oleum Origani.*)

Medical Properties and Uses. It is gently tonic and excitant, and has been used in the form of infusion as a diaphoretic and emmenagogue, and externally as a fomentation; but it is at present scarcely employed.

ORIGANUM MAJORANA. Herba. *Dub.*

Sweet Marjoram.

Off. Syn. ORIGANI MAJORANÆ HERBA. *Ed.*

Marjolaine, *Fr.;* Majoran, Wurstkraut, *Germ.;* Maggiorana. *Ital.;* Mejorana, *Span.*

ORIGANUM. See ORIGANUM.

Origanum Majorana. Willd. *Sp. Plant.* iii. 137; Woodv. *Med. Bot.* p. 345. t. 124. This species of Origanum has a perennial root with numerous stems, which are woody, branching, four-sided, and a foot and a half high. The leaves are sessile, in pairs, ovate, obtuse, entire, downy, and of a pale green colour. The flowers are small, white, and appear successively between the bracteal leaves, which are numerous, and form round compact spikes, of which three or four are placed at the extremity of each peduncle. The corolla is funnel-shaped, with the upper lip erect and roundish, the under divided into three pointed segments.

Sweet marjoram grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe and in the United States. Some authors, however, consider the *O. Majoranoïdes*, which is a native of Barbary, and closely allied to the *O. Majorana*, as the type of the sweet marjoram of our gardens.

This plant has a pleasant odour, and a warm, aromatic bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a large proportion of volatile oil.

It is tonic and gently excitant, but is used more as a condiment in cookery than as a medicine. In domestic practice, its infusion is much employed by the vulgar to hasten the tardy eruption in measles and other exanthematous diseases.

OS. *U.S.*

Bone.

Off. Syn. OSSA. *Ed., Dub.*

Os, *Fr.;* Knochen, *Germ.;* Ossa, *Ital.;* Huesos, *Span.*

Bones are employed in several pharmaceutical processes, and those derived from the domestic quadrupeds, especially the ox, may be assumed as the kind intended for officinal use.

Properties, &c. They are solid, white substances, of a lamellated texture, constituting the skeleton of the superior orders of animals, of which they form the hardest and densest parts. They consist of a cellular tissue of organic matter, the cavities of which are filled up with certain earthy salts, to be mentioned presently. When subjected to destructive distillation, in close vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black matter, containing the earthy salts of the bone, and constituting the species of animal charcoal called *bone-black.* (See *Carbo Animalis.*) The portions which distil over consist of the usual ammoniacal products derived from animal matter. (See *Ammoniæ Murias.*) When calcined in open vessels they lose more of their weight, and are converted into a white friable substance, consisting of the incombustible part, and called by the earlier chemists the *earth of bones.* Treated with boiling water, a small portion of the animal matter is dissolved, consisting of gelatin; but when acted on by water in a *Papin's digester*, the whole of the animal matter is taken up, and the earthy salts, deprived of their cement, crumble into powder, and become diffused through the solution. When subjected to the action of dilute muriatic acid, the gelatin and earthy salts are dissolved, and the bone softens without losing its shape, and becomes semitransparent and flexible. The portion which remains unattacked by the acid is animal matter, having the appearance of cartilage, and the chemical properties of coagulated albumen. This portion of bone is very nutritious, and has been prepared so as to form a wholesome aliment by M. d'Arcet. His process for obtaining it consists in digesting bones in weak muriatic acid for seven or eight days, occasionally renewing the acid, plunging them for a few moments in boiling water, and then subjecting them to a strong current of cold water. The pure animal matter thus procured is converted into cakes of gelatin, called *portable soup*, (*tablettes de bouillon*,) by dissolving in water, concentrating the solution until it gelatinizes, and drying the matter obtained.

Composition. The bones of different animals, and of the same animal at different ages, vary somewhat in their composition. Dry ox-bones, according to Berzelius, consist of cartilage 33.3, phosphate of lime 55.45, carbonate of lime 3.85, fluate of lime 2.90, soda, chloride of sodium, water, &c. 2.45, phosphate of magnesia 2.05 = 100. Fourcroy and Vauquelin's results give a larger quantity of animal matter and carbonate of lime, and a smaller of phosphate of lime. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese.

Uses. Bones are applied to numerous uses. Burnt to whiteness, they furnish phosphate of lime, employed to obtain other phosphates, *phosphoric acid*, and *phosphorus*. Subjected to destructive distillation, they yield *impure carbonate of ammonia*, and empyreumatic oil; and a carbonaceous residue is left, called *bone-black*. Calcined, pulverized, and washed, they form the material of which *cupels* are made. In a divided state, in the form of bone saw-dust, they form an excellent manure. Deprived of their earthy portion by weak acids, they furnish a nutritious substance, proper as an ingredient in broths, or for forming portable soup. By proper treatment with water they furnish gelatin, applicable not only to the purposes of common glue, but also to those of the finer sorts of gelatin, called isinglass, in making animal jellies, and for the fining of wines. (See *Ichthyocolla* and *Cornu Cervi Elaphi.*) The hoof-bones of the ox, when boiled with water, furnish a peculiar oil, called neats-foot oil. (See *Oleum Bubulum.*)

OVUM. *Lond.*

Egg.

"Phasianus Gallus. Ova." *Lond.*

Œuf, *Fr.*; Ei, *Germ.*; Ovo, *Ital.*; Huevo, *Span.*

The common dunghill fowl is supposed to have come originally from India, where it is found in a wild state. It is now domesticated in almost all parts of the globe.

The egg, which is the only officinal product, consists of 1. an exterior covering called the shell; 2. a white, semi-opaque membrane, lining the internal surface of the shell; 3. the white; 4. the yolk. Other distinct parts are recognised by the comparative anatomist, but they have no peculiar interest for the practical physician or pharmaceutist.

1. The shell consists, according to Vauquelin, chiefly of carbonate of lime, with animal matter, and a minute proportion of phosphate of lime, carbonate of magnesia, oxide of iron, and sulphur. When exposed to a high degree of heat in the open air, the carbonic acid is driven off, the animal matter consumed, and lime is left nearly pure.

2. The membrane lining the shell appears to be of an albuminous nature.

3. The white—*albumen ovi*—is a glairy viscid liquid contained in very delicate membranes, without odour or taste, readily soluble in water, coagulable by the stronger acids, by alcohol, and by a heat of 160° F. Exposed in thin layers to a current of air it becomes solid, retaining its transparency and solubility in water. By coagulation it is rendered sapid, white, opaque, and insoluble. At a temperature of 212°, one part of it renders one thousand parts of water in which it has been dissolved opaque. It contains, according to Dr. Bostock, in one hundred parts, 85 of water, 12 of pure albumen, 2.7 of mucus or uncoagulable matter, and 0.3 of saline substances, including soda with traces of sulphur. The white of egg is precipitated by muriate of tin, muriate of gold, subacetate of lead, corrosive sublimate, and tannin. When kept in the fluid state it soon putrefies; but if carefully dried without coagulation it may be long preserved without change, and may be applied in a state of solution to the same purposes as in its original condition.

4. The yolk—*vitellus ovi*—is inodorous, of a bland oily taste, and forms a milky emulsion when agitated with water. It contains water, albumen, a mild fixed oil, and a colouring matter. By heat it is coagulated into a granular solid, which yields the oil by expression.

Medical Properties and Uses. Eggs are applied to various purposes in medicine and pharmacy. The shells powdered and levigated may be used beneficially as an antacid in diarrhœa. In common with oyster shells, they possess the advantage of uniting intimately animal matter with the carbonate of lime, the particles of which are thus more thoroughly isolated, and prove more acceptable to the stomach, than chalk in the finest state of division to which the latter can be brought by mechanical means. The dose and mode of preparation are the same with those of the oyster shell. (See *Testa.*)

The *white* of the egg is used chiefly for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and carrying them with it to the surface. It is also the best antidote for corrosive sublimate, producing with that substance an inert compound of albumen and calomel. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for this purpose to the yolk, and even to mucilage of gum Arabic. Agitated briskly with a lump of alum it coagulates, at the same time dissolving a portion of the alum, and thus forming an astringent poultice, which may be advantageously applied between folds of gauze over the eye, in some states of ophthalmia. (See *Cataplasma Aluminis.*)

The *yolk* in its raw state is thought to be laxative, and is a popular remedy in jaundice. If beneficial in this complaint, it is probably in consequence of affording a mild nutritious diet, acceptable to the stomach, and easily digested. In dyspepsia it is, from this cause, highly useful. Dr. Parrish, of Philadelphia, has found much advantage from recommending to his dyspeptic patients, the habitual use of the yolk of egg beat up with water and a little ginger. In pharmacy, the yolk is highly useful as an intermedium between water and insoluble substances, such as the balsams, turpentine, oils, &c. It is a mistake in our practitioners to recommend the white, instead of the yolk of eggs, in the preparation of emulsions.

PAPAVERIS CAPSULÆ. *Lond.*

Poppy Capsules.

"Papaver somniferum. *Capsulæ maturæ.*" *Lond.*

Off. Syn. PAPAVERIS SOMNIFERI CAPSULÆ. *Ed.;* PAPAVER SOMNIFERUM. Capsulæ maturæ. *Dub.*

Poppy heads; Capsules des pavots, *Fr.;* Kupseln des weissen Mohns, *Germ.;* Capidel papavero, *Ital.;* Cabezas de amapola, *Span.*

See OPIUM.

In England the poppy is cultivated chiefly for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. They are occasionally imported into this country; but as no effect is produced by them, which cannot be as readily obtained from opium, or some one of its preparations, they are little employed; and the framers of the United States Pharmacopœia did not consider them entitled to a place among the articles of the Materia Medica.

The dried poppy capsules vary in size from the dimensions of a small egg to those of the fist. They are of a spheroidal shape, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above its upper surface, and appear to be prolongations of partial septa or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa; but in the dried capsule they are loose in its cavity. The capsules of the black poppy are smaller and more globular than those of the white; and contain dark instead of light-coloured seeds. There appears to be no essential difference in their properties. Both kinds, when fresh, are glaucous, but when dry, as directed in the Pharmacopœias, are of a dirty white or purplish-brown colour, have a consistence somewhat like that of paper, are without smell, and have little taste, unless long chewed, when they are decidedly bitter. Submitted to analysis, they are found to contain principles similar to those of opium, which they yield to water by decoction. They have been employed in France for producing morphia.

Medical Properties and Uses. Dried poppy heads, though analogous to opium in medical properties, are exceedingly feeble. They are sometimes employed in the form of decoction, as an external emollient and anodyne application; and in the shape of emulsion, syrup, or extract, are often used internally by European practitioners to calm irritation, promote rest, and produce generally the narcotic effects of opium.

PETROLEUM. *Lond.*

Petroleum.

Off. Syn, BITUMEN PETROLEUM. *Ed.;* Petroleum. BITUMEN PETROLEUM. PETROLEUM BARBADENSE. *Dub.*

Barbadoes tar; Pétrole. Huile de Gabian, *Fr.;* Steinöl, *Germ.;* Petroleo, *Ital., Span.*

Petroleum belongs to a class of native inflammable substances, called *bitumens.* These are liquids or readily fusible solids, which emit when heated a peculiar smell, burn easily, and leave a very small carbonaceous residue. They are of two kinds, one liquid, called naphtha, the other solid, denominated asphaltum. *Naphtha* is a transparent, yellowish-white, very light and inflammable, limpid liquid, which is found abundantly in Persia. It consists exclusively of hydrogen and carbon. Oxygen not entering into its composition, it is advantageously employed for preserving potassium. During the formation of coal gas, an artificial naphtha is obtained, which by rectification is rendered equally light and limpid with the natural substance. Thus purified, it was discovered by Mr. James Syme of Edinburgh to possess the property of dissolving caoutchouc, and the solution has been usefully applied to the purpose of forming various surgical instruments of that material. It has also been employed by Mr. Mackintosh of Glasgow, for giving a thin coating of caoutchouc to cloth, to render it impermeable to moisture. *Asphaltum* is solid, black, dry, friable, and insoluble in alcohol. These two varieties of bitumen often exist in a state of mixture in nature. When the asphaltum predominates it takes the name of *maltha* or *mineral tar;* when the naphtha is in the larger proportion it is called *petroleum.*

Localities. Petroleum is found principally at Amiano in the Duchy of Parma, at Gabian in France, upon the borders of the Caspian Sea, in the kingdom of Ava, and in Barbadoes, Trinidad, and other West India islands. The wells of petroleum in Ava are said to produce four hundred thousand hogsheads annually. The petroleum from Barbadoes is designated as the officinal variety by the Dublin College.

In the United States petroleum is found in various localities, the principal of which are, on the Kenhawa in Virginia; near Scottsville in Kentucky; in Western Pennsylvania; on Duck Creek in Ohio; and on the shores of Seneka Lake in New York. That found in the latter locality is usually called in this country *Seneka oil*, and similar varieties of petroleum from other native sources are known by the same name.

Properties. Petroleum is a black, rather thick, nearly opaque, inflammable liquid, unctuous to the touch, and possessing a bituminous taste, and strong and tenacious odour. Its sp. gr. varies from 0.730 to 0.878. When subjected to distillation, it yields naphtha, and leaves a solid residue of asphaltum. The petroleum from Ava yielded to Dr. Christison half its bulk of very fine naphtha. It has not been analyzed; but probably consists of hydrogen, carbon, and oxygen.

Medical Properties and Uses. Petroleum is accounted a stimulating antispasmodic and sudorific. It is occasionally given in disorders of the chest, when not attended with inflammation; but is seldom employed as an internal remedy except in the West Indies. In Germany it has been extolled as a remedy for tape-worm. Schwartz's formula in such cases was a mixture of one part of petroleum with one aud a half parts of tincture of assafetida, of which forty drops were given three times a day. Externally petroleum is employed as a stimulating embrocation in chilblains, chronic rheumatism, affections of the joints, and paralysis. It is an ingredient in the popular remedy called *British oil.* The dose of petroleum is from ten to thirty minims, given in any convenient vehicle.

That variety of native petroleum called Seneka oil is used to a considerable extent as an external application in domestic practice. It is lighter coloured, thinner in consistence, and less sapid and odorous than the Barbadoes petroleum, and probably contains more naphtha than the latter. B.

PETROSELINUM. *U. S. Secondary.*

Parsley Root.

"Apium petroselinum. Radix. *The root.*" *U. S.*

Persil, *Fr.;* Petersilie, *Germ.;* Prezzemolo, *Ital.;* Perexil, *Span.*

Apium. *Sex. Syst.* Pentandria Digynia.—*Nat. Ord.* Umbelliferæ.

Gen. Ch. Fruit ovate, striated. *Involucre* one-leafed. *Petals* equal. *Willd.*

Apium Petroselinum. Willd. *Sp. Plant.* i. 1475; Woodv. *Med. Bot.* p. 118. t. 45. Parsley has a biennial root, with an annual, round, furrowed, jointed, erect, branching stem, which rises about two feet in height. The radical leaves are compound, pinnated in ternaries, with the leaflets smooth, divided into three lobes, and notched at the margin. In the cauline leaves, the segments of the leaflets are linear and entire. The flowers are small, pale yellow, and disposed in terminal compound umbels, with a one or two leaved general involucre, and partial ones composed of six or eight leaflets. The petals are five, roundish, and inflexed at their apex. The seeds are small, ovate, flat on one side, convex on the other, of a dark green colour, and marked with five longitudinal ridges. They have a strong, terebinthinate odour, and a warm aromatic taste.

The plant is a native of Sardinia and other parts of southern Europe and is cultivated every where in gardens. All parts of it contain an essential oil, to which it owes its medicinal virtues, as well as its use in seasoning. The root is the part directed by the Pharmacopœia, though the seeds are at least equally efficient.

The root is spindle-shaped, about as thick as the finger, externally white and marked with close annular wrinkles, internally fleshy and white, with a yellowish central portion. It has a pleasant smell, and a sweetish slightly aromatic taste; but loses these properties by long boiling, and by the action of time. It should be employed in the recent state.

Medical Properties and Uses. Parsley root is said to be aperient and diuretic, and is occasionally used in nephritic and dropsical affections, in connexion with more active medicines. It is highly recommended by Professor Chapman. The usual form of administration is that of strong infusion. W.

PHYTOLACCÆ BACCÆ. *U.S. Secondary.*

Poke Berries.

"Phytolacca decandra. Baccæ. *The berries*" *U. S.*

PHYTOLACCÆ RADIX. *U.S. Secondary.*

Poke Root.

"Phytolacca decandra. Radix. *The root.*" *U.S.*

PHYTOLACCA. *Sex. Syst.* Decandria Decagynia.—*Nat. Ord.* Phytolacceæ.

Gen. Ch. Calyx none. *Petals* five, calycine. *Berry* superior, ten-celled, ten-seeded. *Willd.*

Phytolacca decandra. Willd. *Sp. Plant.* ii. 822; Bigelow, *Am. Med. Bot.* i. 39; Barton, *Med. Bot.* ii. 213. This is an indigenous plant with a very large perennial root, often five or six inches in diameter, divided into two or three principal branches, soft, fleshy, fibrous, whitish within, and covered with a brownish cuticle. The stems, which are annual, frequently grow to the height of six or eight feet, and divide into numerous spreading branches. They are round, very smooth, of a green colour when young, but purple after the berries have ripened. The leaves are scattered, ovate oblong, entire, pointed, smooth, ribbed beneath, and supported on short footstalks. The flowers are numerous, small, and grow in long racemes, which are sometimes erect, sometimes drooping. The corolla consists of five ovate, concave petals, folding inwards, and of a whitish colour. The germ is green. There are ten stamens, and the same number of pistils. The raceme of flowers becomes a cluster of dark purple, almost black, shining berries, flattened above and below, and divided into ten cells, each of which contains one seed.

The poke is abundant in all parts of the United States, flourishing along fences, by the borders of woods, and especially in newly cleared and uncultivated fields. It also grows spontaneously in the North of Africa and the South of Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke-weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit, and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of spinage. The ashes of the dried stems and leaves contain a very large proportion of potassa, yielding, according to Braconnot, not less than forty-two per cent. of the pure caustic alkali. In the plant the potassa is neutralized by an acid closely resembling the malic, though differing from it in some respects. The leaves, berries, and root are used in medicine, but the two latter only are mentioned in the Pharmacopœia. The root abounds most in the active principles of the plant. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of summer, when the footstalks begin to redden.

The *berries* contain a succulent pulp, and yield upon pressure a large quantity of fine purplish-red juice. They have a sweetish, nauseous, slightly acrid taste, with little odour. The colouring principle of their juice is evanescent, and cannot be applied to useful purposes in dyeing, from the difficulty of fixing it. Alkalies render it yellow; but the original colour is restored by acids. The juice contains saccharine matter, and after fermenting, yields alcohol by distillation.

The *dried root* is of a light yellowish-brown colour externally, very much wrinkled, and when in transverse slices, exhibits on the cut surface numerous concentric rings, formed by the projecting ends of fibres, between which the intervening matter has shrunk in the drying process. The structure internally in the older roots is firm and almost ligneous; the colour yellowish-white, alternating with darker circular layers. There is no smell; the taste is slightly sweetish, and at first mild, but followed by a sense of acrimony The active matter is imparted to boiling water and alcohol.

Medical Properties and Uses. Poke is emetic, purgative, and somewhat narcotic. As an emetic it is very slow in its operation, frequently not commencing in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and bowels. The vomiting produced by it is said not to be attended with much pain or spasm; but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In over-doses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions. It has been proposed as a substitute for ipecacuanha; but the slowness and long continuance of its action, and its tendency to purge, wholly unfit it for the purposes which that emetic is calculated to fulfil. In small doses it acts as an alterative, and has been highly recommended in the treatment of chronic rheumatism. The dose of the powdered root, as an emetic, is from ten to thirty grains; as an alterative, from one to five grains. A saturated tincture of the berries prepared with diluted alcohol may be given in rheumatic cases, in the dose of a fluidrachm three times a day. A strong infusion of the leaves or roots has been recommended in piles.

An ointment prepared by mixing a drachm of the powdered root or leaves with an ounce of lard, has been used with advantage in psora, tinea capitis, and some other forms of cutaneous disease. It occasions at first a sense of heat and smarting in the part to which it is applied. An extract made by evaporating the expressed juice of the recent leaves has been used for the same purpose, and acquired at one time considerable repute as a remedy in cancer.

PIMENTA. *U.S.*

Pimento.

"Myrtus pimenta. Baccæ. *The berries.*" *U.S.*

Off. Syn. PIMENTÆ BACCÆ. Myrtus Pimenta. Baccæ. *Lond.;* MYRTI PIMENTÆ FRUCTUS, *Ed.;* PIMENTA. MYRTUS PIMENTA. Fructus. *Dub.*

Allspice, Jamaica pepper; Piment, Poivre de la Jamaique, *Fr.;* Nelkenpfeffer, *Germ.;* Pimenti, *Ital.;* Pimienta de la Jamaica, *Span.*

Myrtus. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Myrtaceæ.

Gen. Ch. Calyx five-cleft, superior. *Petals* five. *Berry* two to five-celled, many-seeded. *Willd.*

By professor Lindley, of London, the pimento tree has been withdrawn from the *Myrtus*, and erected into a new genus, by the title of *Pimenta*, of which the following character is given. "*Calyx* five-cleft; *petals* five; *ovary* two-celled; *ovules* solitary apense; *style* straight; *stigma* somewhat capitate." (*Loudon's Encyc. of Plants.*) This genus contains but a single species, which is named *Pimenta vulgaris.* We adhere, however, to the officinal title.

Myrtus Pimenta. Willd. *Sp. Plant.* ii. 973; Woodv. *Med. Bot.* p. 541. t. 194. This species of myrtle is a beautiful tree, about thirty feet high, with a straight trunk, much branched above, and covered with a very smooth gray bark. Its dense and ever-verdant foliage gives it at all times a refreshing appearance. The leaves, which are petiolate, vary in shape and size; but are usually about four inches long, elliptical, entire, blunt or obtusely pointed, veined, and of a deep shining green colour. The flowers are small, without show, and disposed in panicles upon trichotomous stalks, which usually terminate the branches. The fruit is a spherical berry, crowned with the persistent calyx, and when ripe is smooth, shining, and of a black or dark purple colour. The tree exhales an aromatic fragrance, especially during the summer months, when it is in flower.

It is a native of the West Indies, Mexico, and South America, and is particularly abundant in Jamaica, whence its fruit received the name of *Jamaica pepper.* The berries are the officinal portion of the plant. They are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation.

Properties. The berries, as they reach us, are of different sizes, small, round, wrinkled, umbilicate at the summit, of a brownish colour, and when broken present two cells, each containing a black hemispherical seed. They have a fragrant odour, thought to resemble that of a mixture of cinnamon, cloves, and nutmeg: hence the name of *allspice*, by which they are best known in this country. Their taste is warm, aromatic, pungent, and slightly astringent. They impart their flavour to water, and all their virtues to alcohol. The infusion is of a brown colour, reddens litmus paper, and affords a black precipitate with the salts of iron. They yield a volatile oil by distillation. (See *Oleum Pimentæ.*) Neumann ascertained that their aromatic flavour depends on the volatile oil, their pungency in great measure upon a substance soluble in alcohol and insoluble in water. By a minute analysis, M. Bonastre obtained from them a volatile oil, a green fixed oil, a concrete oleaginous substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, colouring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimento, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medical properties of the berries depend; and as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to M. Bonastre, the shell contains 10 per cent. of the volatile, and 8 of the fixed oil, the seeds only 5 per cent. of the former, and 2.5 of the latter. Berzelius considers the green fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little chlorophylle.

Medical Properties and Uses. Pimento is a warm, aromatic stimulant, used in medicine chiefly as an adjuvant to tonics and purgatives, the taste of which it serves to cover, while it increases their warmth and renders them more acceptable to the stomach. It is particularly useful in cases attended with much flatulence. It is, however, much more largely employed as a condiment than as a medicine. The dose is from ten to forty grains.

Piper nigrum. Willd. *Sp. Plant.* i. 159; Woodv. *Med. Bot.* p. 721. t. 246. The pepper vine is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark green colour, and attached by strong, sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are of a red colour when ripe.

The vine grows wild in Cochin-china and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, and many other places in the East. We are told by Crawford, that the best pepper is raised in Malabar; but Europe and America derive their chief supplies from Sumatra and Java. The vine is propagated by cuttings, and is supported by props, or by trees of various kinds planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The berries are gathered before they are all perfectly ripe, and upon being dried, become black and wrinkled.

White pepper is the ripe berry deprived of its skin by maceration in water and subsequent friction, and afterwards dried in the sun. It has less of the peculiar virtues of the spice than the black pepper, and is seldom employed in this country.

Properties. The dried berries are about as large as a small pea, externally blackish and wrinkled, internally whitish, of an aromatic smell, and a hot, pungent, almost fiery taste. They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar crystalline matter called *piperin*, an acrid concrete oil of a green colour, a balsamic volatile oil, a coloured gummy substance, an extractive matter like that found in leguminous plants capable of being precipitated by infusion of galls, a portion of bassorin, uric and malic acids, lignin, and various salts. Of these principles the piperin and the acrid concrete oil are those which have attracted most attention. *Piperin* was discovered by professor Œrsted of Copenhagen, who considered it a vegetable alkali, and the active principle of pepper. Pelletier, however, utterly denies its alkaline nature and medical activity, and ascribes all the effects supposed to have been obtained from it to a portion of the acrid concrete oil with which it is mixed when not very carefully prepared. He considers it a resin analogous to that which Vauquelin found in cubebs. When perfectly pure, *piperin* is in colourless transparent crystals, without taste, fusible at 212°, insoluble in cold water, slightly soluble in boiling water which precipitates it upon cooling, soluble in alcohol, ether, and acetic acid, decomposed by the concentrated mineral acids, with the sulphuric becoming of a blood-red colour, with the nitric, first of a greenish-yellow, then orange, and ultimately red. It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the residue to the action of an alkaline solution by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously, or by a gentle heat. Crystals of piperin are deposited, and may be purified by alternate solution in alcohol or ether, and crystallization. The taste of pepper depends on the peculiar concrete oil before alluded to, and probably also on the volatile oil. The former is of a deep green colour, the latter is limpid, colourless, becoming yellow by age, of a strong odour, and of a taste less acrid than the pepper. The medicinal activity of pepper probably depends on these two ingredients.

Medical Properties and Uses. Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been employed as a condiment and medicine. Its culinary uses at present are too well known to require notice. Its chief medicinal application is to excite the languid stomach, and correct flatulence. It was long since occasionally administered for the cure of intermittents; but its employment for this purpose had passed from the hands of the profession into those of the vulgar, till recently revived by an Italian physician, to be again consigned to forgetfulness. Piperin has also been employed in the same complaint; and has been recommended as superior even to the sulphate of quinia; but experience has not confirmed the first reports in its favour. That in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt; but it is not comparable to the preparations of bark, and is probably less active than the alcoholic extract of pepper. When perfectly pure it is inert. In those cases of intermittents in which the stomach is not duly susceptible to the action of quinia, as in some instances of drunkards, pepper may be found a useful adjuvant to the more powerful febrifuge.

The dose of pepper is from five to twenty grains. It may be given in the state of the berry or in powder; but is more energetic in the latter. Piperin has been given in doses varying from one to six or eight grains.

PIPER. See PIPER.

Piper longum. Willd. *Sp. Plant.* i. 161; Woodv. *Med. Bot.* p. 724. t. 247. This species of Piper differs from its congeners in having its lower leaves cordate, petiolate, seven-nerved, its upper oblong cordate, sessile, and five-nerved; its flowers in dense, short, terminal, and nearly cylindrical spikes; and its fruit, consisting of very small one-seeded berries or grains, embedded in a pulpy matter. It is a native of South-eastern Asia, and is produced abundantly in Bengal and many parts of Hindostan. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant and dried in the sun.

Long pepper is cylindrical, an inch or more in length, indented on its surface, of a dark gray colour, a weak aromatic odour, and a pungent fiery taste. M. Dulong found its chemical composition to be closely analogous to that of black pepper as ascertained by Pelletier. Like that it contains *piperin*, a concrete oil upon which its burning acrimony depends, and a volatile oil to which it probably owes its odour. Its medical virtues are essentially the same with those of the black pepper; but it is considered inferior to that spice, and is seldom used.

Pinus Abies. Willd. *Sp. Plant.* iv. 506; Woodv. *Med. Bot.* p. 4. t. 2.—*Abies communis.* Lindley *in Loudon's Encyc. of Plants.*—*Abies excelsa.*

De Candolle. The Norway spruce is a very lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, which stand thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green colour, and shining on the upper surface. The male aments are purple and axillary, the female of the same colour, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges.

This tree is a native of Europe and Northern Asia. Though designated as the source of Burgundy pitch, it furnishes but a part of the substance sold under that name by the druggists. Tingley asserts that the real Burgundy pitch is obtained from the *Pinus picea*, or European silver fir tree; and the same fact is stated by Fée. According to Geiger, who is probably correct, it is procured from both species. To obtain the *pitch*, portions of the bark are removed so as to lay bare the wood, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the East of France. We are told that the greater portion is collected in the neighbourhood of Neufchatel.

From other species of pine in different parts of Europe, a similar product is obtained and sold by the same name. It is prepared by removing the juice which concretes upon the bark of the tree or upon the surface of incisions, called *galipot* by the French, and purifying it by melting and straining, either through cloth or a layer of straw.

A fictitious Burgundy pitch is also made by melting together common pitch, resin, and turpentine, and agitating the mixture with water, which gives it the requisite yellowish colour. Its odour is different from that of the genuine.

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state it is hard, brittle, quite opaque, of a yellowish or brownish-yellow colour, and a weak terebinthinate taste and odour. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of essential oil.

Under the name of ABIETIS RESINA, the London College directs the concrete juice of the *spruce fir*, as taken immediately from the bark of the tree, without any preparation. It is the *Thus* or *Frankincense* of the former London and present Dublin Pharmacopœia. "It is in the form of solid brittle tears, of a brownish-yellow colour on the outside, and internally white, and emits a very agreeable odour upon burning." (*Thomson's Dispensatory.*) Though ascribed to the *Pinus Abies*, it is probably obtained also from other species; and we have been told by an apothecary from London, that an article exactly resembling our common white turpentine when perfectly dried, is sold as frankincense in the shops of that city.

Medical Properties and Uses. Applied to the skin in the shape of a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight degree of inflammation and serous effusion without separating the cuticle. Sometimes it excites a papillary or vesicular eruption; and we have known it to act upon the surface as a violent poison, giving rise to excessive pain, tumefaction, and redness, followed by vesication and even ulceration. It is used chiefly in cases of slight chronic pains of a rheumatic character, or in chronic affections of the chest or abdominal viscera, which call for a gentle but long continued revulsive action upon the skin.

The *Abietis Resina*, or *Frankincense*, is used only as an ingredient of plasters.

PIX CANADENSIS. *U.S.*

Hemlock Pitch.

"Pinus Canadensis. Succus concretus præparatus. *The prepared concrete juice.*" *U. S.*

Pinus. See TEREBINTHINA.

Pinus Canadensis. Willd. *Sp. Plant.* iv. 505.—*Abies Canadensis.* Michaux, *N. Am. Sylv.* iii. 185. This is the *hemlock spruce* of the United States and Canada. When of full growth it is often seventy or eighty feet high, with a trunk two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. The branches are slender, and dependent at their extremities. The leaves are very numerous, six or eight lines long, flat, denticulate, and irregularly arranged in two rows. The strobiles are ovate, little longer than the leaves, pendulous, and situated at the ends of the branches.

The tree is abundant in Canada, Nova Scotia, and the more northern parts of New England; and is found in the elevated and mountainous regions of the Middle States. Its bark abounds in the astringent principle, and is much used for tanning in the northern parts of the United States. It contains much less juice than some other species of pine; and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about or have begun to decay, the juice exudes spontaneously, and hardens upon the bark in consequence of the partial evaporation or oxidation of its essential oil. The bark thus incrusted is stripped from the tree, broken into pieces of convenient size, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. It is brought to Philadelphia from the North of Pennsylvania, in dark coloured brittle masses, which on being broken exhibit numerous minute fragments of bark, interspersed through their substance. From these it is purified in the shops by melting and straining through linen or canvass.*

Thus prepared it is hard, brittle, quite opaque, of a dark yellowish-brown colour which becomes still darker by exposure to the air, of a weak peculiar odour, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and melts at 198° F. Its constituents are resin and a minute proportion of essential oil. It is most generally known by the incorrect name of *hemlock gum*.

Medical Properties and Uses. Hemlock pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. W.

PIX LIQUIDA. *U.S.*

Tar.

"Pinus palustris et aliæ. Terebinthina empyreumatica. *The impure turpentine procured by burning.*" *U. S.*

Off. Syn. PIX LIQUIDA. Pinus sylvestris. Resina præparata liquida. *Lond.;* PINI RESINA EMPYREUMATICA, vulgo, PIX LIQUIDA. *Ed.;* PIX LIQUIDA. E speciebus Pini diversis. *Dub.*

Gondron, *Fr.;* Theer, *Germ.;* Pece liquida, *Ital.;* Alquitran, *Span.*

The tar used in this country is prepared from the wood of various species of pine, particularly the *Pinus palustris* of the Southern States, the *P. australis* of Michaux. (See *Terebinthina.*) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concentrated in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile, and are then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the centre, where a small cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into the cavity in the centre of the mound, and passes thence by the conduit into the ditch, whence it is emptied into barrels. Immense quantities of tar are thus prepared in North Carolina and the south-eastern parts of Virginia, sufficient, after supplying our own consumption, to afford a large surplus for exportation.

Considerable quantities of tar are also prepared in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Alleghany mountains, from the *Pinis rigida*, or pitch pine, and perhaps from some other species.

Properties. Tar has a peculiar empyreumatic odour, a bitterish resinous somewhat acid taste, a colour almost black, and a tenacious consistence intermediate between that of a liquid and solid. It consists chiefly of resin, united with acetic acid and empyreumatic oil, and coloured with charcoal. The empyreumatic oil obtained by distillation from tar has been ascertained by Dr. Reichenbach, of Moravia, to contain six distinct principles, which he has named *paraffine*, *eupione*, *creosote*, *picamar*, *capnomor*, and *pittacal.* Of these only picamar and creosote merit particular attention; the former as the principle to which tar owes its bitterness, the latter as the one upon which it probably depends chiefly for its medical virtues. (See *Creosote* in the Appendix.) Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water.* By long boiling the liquid parts are evaporated, and the tar is converted into *pitch*, the Pix Nigra of the London College.

Medical Properties and Uses. The medical properties of tar are similar to those of the turpentines. It is sometimes used in chronic coughs, and when the disease depends on chronic bronchial inflammation, with occasional advantage. Little benefit can be expected from it in genuine phthisis, in the treatment of which it was formerly highly recommended. Dr. Bateman employed it advantageously as an internal remedy in ichthyosis. Its vapour, inhaled into the lungs, has been found serviceable in numerous cases of bronchial disease. Externally applied, in the state of ointment, it is a very efficient remedy in some cases of tinea capitis, or scald head; and has been used with advantage in foul or indolent ulcers, and some other affections of the skin.

It may be used in the form of tar water, *Aqua Picis Liquidæ*, or in substance made into pills with wheat flour, or mixed with sugar in the form of an electuary. The dose is from half a drachm to a drachm, and may be repeated so as to amount to three or four drachms daily.

PLUMBUM.

Lead.

Plomb, *Fr.;* Blei, *Germ.;* Lood, *Dutch;* Piombo, *Ital.;* Plomo, *Span.;* Chumbo, *Port.*

Lead is not officinal in its metallic state; but enters into a number of important medicinal preparations. It occurs in nature in three principal states—as an oxide; as a sulphuret called *galena;* and as a salt, forming the native sulphate, phosphate, carbonate, chromate, molybdate, and arseniate of lead. The oxide is rare, but galena is exceedingly abundant and diffused, and is the ore from which all the lead of commerce is extracted. The process of extraction consists merely in melting the ore in contact with charcoal. Mines of galena occur in different parts of the world, but the richest and most extensive are found in our own country. The lead region of the United States extends in length from the Wisconsin in the north, to the Red river of Arkansas in the south, and in breadth about one hundred and fifty miles. It is only of latter years that these mines have been extensively worked; and they were estimated, in 1834, to yield ten millions of pounds.

Properties. Lead is a soft, bluish-white, and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar smell when rubbed. It undergoes but little change in the air, but is corroded by the combined action of air and water. Its sp. gr. is 11.4, melting point about 600°, and equivalent number 103.6. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame, throwing off dense yellow fumes. The best solvent of lead is nitric acid; but the presence of sulphuric acid destroys, and that of muriatic acid lessens its solvent power, on account of the compounds which these acids form with lead being nearly insoluble. Lead forms four oxides, a dinoxide, protoxide, peroxide, and red oxide. The *dinoxide* consists of two equivalents of lead, and one of oxygen. The *protoxide*, called in commerce *massicot*, may be obtained by calcining, in a platinum crucible, the subnitrate of lead, formed by precipitating a solution of the nitrate with ammonia. On a large scale it is manufactured by exposing melted lead to the action of the air. Its surface becomes incrusted with a gray pellicle, which being scraped off, is quickly succeeded by another; and the whole of the metal, being in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of protoxide and metallic lead. This, by a moderate exposure to heat, absorbs more oxygen, and is converted entirely into protoxide. This oxide has a yellow colour, and is the one present in the salts of lead. It consists of one equiv. of lead 103.6, and one of oxygen 8=111.6. A variety of this oxide, called *litharge*, is very much used in pharmacy, and is officinal in all the Pharmacopœias. (See *Plumbi Oxidum Semivitreum.*) The *peroxide*, called also *puce* oxide, from its *flea*-brown colour, may be obtained by treating red lead with nitric acid. The acid takes up the protoxide, and leaves the peroxide, which may be purified by washing with boiling water. It is a tasteless powder, of a dark-brown colour. When heated to redness it loses half its oxygen, and becomes protoxide. It consists of one equiv. of lead 103.6, and two equiv. of oxygen 16=119.6. The *red oxide*, called in commerce *minium*, or *red lead*, is officinal with the Edinburgh College, and is described under another head. (See *Oxidum Plumbi Rubrum.*) Lead combines also with chlorine, forming a sparingly soluble chloride. This combination is precipitated whenever a muriate is added to a soluble salt of lead. The salts of lead are numerous and important. The nitrate is in the form of white crystals, and the sulphate in that of an insoluble white powder.

The best tests of this metal are sulphuretted hydrogen, and a solution of hydriodate of potassa. The former produces a dark-brown precipitate of sulphuret of lead, and the latter a yellow one of iodide of lead.

Medical Properties and Uses. The effects of lead in its various combinations are those of a sedative and astringent. It is used internally for the purpose of reducing vascular action, and of restraining inordinate discharges; and externally as an abater of inflammation. When introduced into the system by imperceptible degrees, it acts injuriously on the nervous system, producing a peculiar colic, called *lead colic*, and palsy, which is almost always partial and incomplete. It has been proved by Dr. A. T. Thomson, of London, that of all the ordinary preparations of lead, the carbonate is the most virulent; and that those salts which are easily convertible into the carbonate are also highly poisonous. On the other hand, those combinations which are not susceptible of this change, such as the nitrate, muriate, &c. may be given in large doses to inferior animals, without perceptible inconvenience. If these views should prove correct, it would follow that the best antidote to the poisonous effects of lead, would be the free use of vinegar, to convert the carbonate into the soluble acetate.

According to M. Gendrin, sulphuric acid, prepared like lemonade, and used both internally and externally, is a remedy and prophylactic for the poisonous effects of lead, especially the lead colic. Its utility appears to have been fully tested in a large white lead manufactory in France. *Amer. Journ. of Med. Sci.* xv. 528.

PLUMBI ACETAS. *U.S.*, *Lond.*, *Dub.*

Acetate of Lead.

Off. Syn. ACETAS PLUMBI. *Ed.*

Sugar of lead; Saccharum Saturni, Cerussa acetata, *Lat.;* Acétate de plomb, Sucre de plomb, Sel de Saturne, *Fr.;* Essigsaures Bleioxyd, Bleizucker, *Germ.;* Zucchero di Saturno, *Ital.;* Azucar de plomo, *Span.*

Directions are given by the three British Colleges for preparing acetate of lead; but as it is seldom or never prepared by the apothecary, and may be obtained in the greatest perfection, and at a cheap rate, from the manufacturing chemist, it is more properly placed in the United States Pharmacopœia in the catalogue of the Materia Medica.

Preparation. Sugar of lead is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar; and they are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal becomes protoxidized, and dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving, by the assistance of heat, litharge, or the protoxide of lead obtained by calcination, in an excess of distilled vinegar or purified pyroligneous acid, contained in leaden boilers. The oxide is quickly dissolved, and when the vinegar has become saturated, the solution is transferred to other vessels to cool and crystallize. The crystals having formed, the mother waters are decanted, and, by a new evaporation, made to yield a new crop. These are generally of a yellow colour, but may be purified by repeated solutions and crystallizations.

The processes of the British Colleges for preparing this salt, agree in directing the solution of carbonate of lead (white lead) in dilute acetic acid, or distilled vinegar, but we do not deem it expedient to copy them, as they are ineligible and expensive.

---

* This plaster forms the basis of a number of other plasters.

Sugar of lead is extensively manufactured in Germany, Holland, France, and England; its principal consumption being caused by the arts of dyeing and calico-printing, in which it is employed to form with alum the acetate of alumina, which is used as a mordant. By far the larger part consumed in the United States is obtained from foreign countries, principally from England and France; a comparatively small portion only being made in our own laboratories. The importation for the year ending in September 1832, exceeded three hundred and fifty thousand pounds.

Properties. Acetate of lead is a white salt, crystallized in brilliant needles, which have the shape of long prisms, terminated by dihedral summits. Its taste is at first sweet and afterwards astringent. Exposed to the air, it effloresces slowly. It dissolves in four times its weight of cold, and in a much smaller quantity of boiling water. It is soluble also in alcohol. Carbonic acid water, as well as common water, which uniformly contains this acid, produces a slight precipitate of carbonate of lead in the commercial acetate, an occurrence which seems to depend upon the presence of a slight excess of base in the latter, and which may be prevented by the addition of a small portion of vinegar, or of dilute acetic acid. In pure distilled water, free from carbonic acid, it ought to dissolve entirely, and form a clear solution. Sulphuric acid or a soluble sulphate, when added to a solution of the acetate of lead, produces instantly a precipitate of sulphate of lead; but the most important property of sugar of lead is its power of dissolving a large quantity of protoxide of lead. (See *Liquor Plumbi Subacetatis.*) It consists of one equiv. of acetic acid 51.48, one of protoxide of lead, 111.6, and three of water 27 = 190.08.

Incompatibles. Acetate of lead is decomposed by all acids, and by those soluble salts formed from them, which produce with protoxide of lead insoluble or sparingly soluble compounds. Acids of this character are the sulphuric, muriatic, citric, and tartaric. It is also decomposed by lime-water, and by ammonia, potassa, and soda; the two last, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the sulphate of lime and common salt, which such water usually contains. With sulphuretted hydrogen, it gives a black precipitate of sulphuret; and with the solution of acetate of ammonia, a white one of carbonate, in consequence of the carbonic acid diffused through this acetate as ordinarily prepared.

Medical Properties and Uses. Acetate of lead, in medicinal doses, is a powerful astringent and sedative, and in large ones, an irritant poison, producing inflammation of the alimentary canal, if the patient survive for some time; but if the quantity taken be large, the stomach is apt to present a peculiar blanched appearance. The danger, however, from over-doses of sugar of lead is not so great as is generally supposed. It has sometimes been given in pretty large doses in regular practice, without any bad effects, and cases are on record where a quarter of an ounce has been swallowed without proving fatal. According to Dr. A. T. Thomson, the poisonous quality of this salt is to be attributed to its tendency to become converted into carbonate in the stomach; and hence he finds that if it be mixed with vinegar, it may be freely and safely administered in medical practice. The principal diseases in which it has been exhibited, are hemorrhages, particularly from the lungs, intestines, and uterus. Its effect in restraining the discharge of blood is admitted to be very powerful. It has also been used with advantage in certain forms of dysentery and diarrhœa, and has been recommended in particular stages of cholera infantum. But the practitioner should always bear in mind, that this medicine, when long continued in small doses, is liable to produce dangerous constitutional effects. These effects are of two kinds; 1. an affection of the alimentary canal, attended with violent pain and obstinate constipation, called *colica pictonum*, or *lead colic;* 2. a chronic affection of the muscles, especially of the extensors of the upper extremities, characterized by an excessive wasting of these organs, and denominated *lead palsy*. Both these affections are very apt to be excited in those artisans who work in lead. Acetate of lead, when combined with opium, is less apt to produce these deleterious effects, and, according to Dr. Thomson, when taken with vinegar, is rendered entirely safe, as above mentioned. Its bad effects are also prevented by the use of dilute sulphuric acid. (See *Plumbum.*) Its solution is frequently used as a collyrium; and applied by means of cloths, or mixed with crumb of bread, it forms a good application to superficial inflammation. For the latter purpose, the subacetate of lead is better. (See *Liquor Plumbi Subacetatis Dilutus.*) The dose of sugar of lead is from one to two grains, in the form of pill, repeated every two or three hours. The solution for external use may be made by dissolving from two drachms to half an ounce of the salt in a pint of water; and if it be wanted clear, a fluidrachm of vinegar or dilute acetic acid may be added, which immediately dissolves the carbonate of lead, to which its turbidness is owing. The usual strength of the solution as a collyrium is from one to two grains to the fluidounce of water.

Off. Prep. Ceratum Plumbi Acetatis, *Lond.*, *Ed.*, *Dub.;* Liquor Plumbi Subacetatis, *U.S.* B.

PLUMBI CARBONAS. *U.S.*

Carbonate of Lead.

Off. Syn. PLUMBI SUBCARBONAS. *Lond.;* CARBONAS PLUMBI. *Ed.;* PLUMBI CARBONAS. CERUSSA. *Dub.*

White lead; Céruse, Carbonate de plomb, Blanc de plomb, Blanc de céruse, *Fr.;* Bleiweiss, *Germ.;* Cerussa, *Lat.*, *Ital.;* Albayalde, *Span.*

Preparation. Carbonate of lead is prepared by two principal methods. By one method it is obtained by passing a stream of carbonic acid, proceeding from a fire of charcoal, through a solution of subacetate of lead. The carbonic acid combines with the excess of protoxide and precipitates as carbonate of lead, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of protoxide, is again brought to the state of subacetate, when it is treated with carbonic acid as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate, and of being decomposed by carbonic acid. The carbonate obtained is washed, dried by a gentle heat, and thrown into commerce. This process, which produces white lead of the first quality, was invented and made public by Thenard, about the year 1802, and is that which is pursued in France and Sweden. The other method, which consists in exposing lead to the vapours of vinegar, originated in Holland, and is pursued in England and the United States; but in England, with some modifications, which are kept secret. We shall describe the process as pursued by our own manufacturers. The lead is cast into thin sheets, made by pouring the melted metal over a long sheet-iron shovel, with a flat bottom, and raised edges on its sides, which is held in a slanting direction over the melting pot. As many of these sheets are then loosely rolled up as may be sufficient to form a cylinder, five or six inches in diameter, and seven or eight high, which is placed in an earthen pot containing about half a pint of vinegar, and having within a few inches from the bottom, three equidistant projecting portions in the earthenware, on which the cylinder of lead is designed to rest, in order to keep it from contact with the vinegar. The pots thus prepared are placed side by side, in horizontal layers, in a building roughly constructed of boards, with interstices between them. The first layer is covered with boards, on which a stratum of refuse straw from the stables is strewed; and fresh layers of pots, boards, and straw, are successively placed, until the whole building is filled. The sides also are enclosed with straw. The *pile* of pots, called a bed, is allowed to remain undisturbed for about six weeks, at the end of which time, it is taken down, and the cylinder of lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in water, whereby it is washed and reduced to fine powder, and finally dried in long, shallow reservoirs, usually heated by steam.

The theory of the above process is not well understood. It is generally supposed that the vinegar by its decomposition furnishes the oxygen and part of the carbonic acid to the lead, the remainder of this acid being supplied by the decomposition of the straw, which is found to undergo a kind of fermentation. This fermentation maintains the requisite degree of heat, which should be about 113°. If the temperature falls below 95°, part of the lead escapes corrosion, and if it rises above 122°, the product is yellow. According to Berzelius, the white lead made by this process is of better quality, the more perfectly the air is excluded, a fact, which, if well founded, proves that the metal is not oxidized at the expense of the oxygen of the air. It is never perfectly white; for the fermentation of the straw generating a little sulphuretted hydrogen prevents it from being so. It would be an improvement in the process, if the requisite temperature could be maintained without the use of straw; and it is probable that a mode of effecting this object is one peculiarity of the English process. The form of the acetic acid usually employed is common vinegar, as has been already stated; but the variable nature of this liquid as to strength and purity is an objection to its use; and, accordingly, other forms of this acid have been substituted for it with advantage, such as the purified acetic acid from wood, sufficiently diluted, and potato vinegar.

The consumption of white lead is principally supplied from our own manufactories. Its importation fell off particularly in 1829, as a consequence of the tariff of 1828. In the latter year about three millions of pounds of white and red lead were received from abroad; in 1832, the amount was but little more than half a million.

Properties. Carbonate of lead is a heavy, opaque, insoluble substance, in powder or friable lumps, of a fine white colour, inodorous, and nearly insipid. Its beauty as a pigment depends in great measure on the purity of the lead from which it is manufactured. It is sometimes adulterated with chalk, or sulphate of baryta in fine powder. Chalk may be detected by dissolving the suspected white lead in vinegar, and adding oxalate of ammonia, which will cause a white precipitate; and if sulphate of baryta be present, it will remain undissolved on the addition of nitric acid. Carbonate of lead is an anhydrous salt, and consists of one equivalent of carbonic acid 22.12, and one of protoxide of lead 111.6 = 133.72. It hence appears that the London College is in error, in calling it a *sub*-carbonate.

Medical Properties and Uses. White lead is ranked in the materia medica as an astringent and sedative. It is employed externally only, being used as an application to ulcers, and to inflamed and excoriated surfaces. It has been recommended as an external application in facial neuralgia. (*Journ. de Pharm.* xx. 603.) It is used either by sprinkling the powder on the part, or in the form of cerate or ointment. (See *Ceratum* and *Unguentum Plumbi Carbonatis.*) Its external use, however, is viewed by many practitioners as extremely dangerous, on account of the risk of absorption; but the danger is certainly overrated, as we have the testimony of respectable physicians that they frequently use it in this way, without the least unpleasant result.

Of the different preparations of lead, the carbonate is considered to be the most virulently poisonous. Being very extensively manufactured for the purposes of the arts, it is that preparation also which most frequently produces the peculiar spasmodic colic, called *colica pictonum.* This disease is characterized by pain about the region of the navel, and obstinate constipation, attended with a frequent desire to evacuate the bowels, and is supposed to depend upon a spasmodic constriction of the intestinal tube, particularly of that portion called the colon. The principal indications in the treatment are, first to allay the spasm, and then to evacuate the bowels by the gentlest means. Opium and mild aperients are accordingly the best remedies, and among the latter castor oil and sulphate of magnesia are to be preferred. Indeed this latter appears peculiarly adapted to the case; for while it acts as an aperient, it operates as a counterpoison, by forming the inert sulphate of lead with any preparation of the metal which it may meet with in the bowels. Calomel is often useful in particular states of the disease, and if it happen to induce ptyalism, the disease immediately yields.

If the views of Dr. A. T. Thomson should be confirmed, of the comparative safety of the soluble salts of lead, they would teach the propriety of allowing the workmen in white lead works, a daily portion of vinegar with their food. Gendrin recommends as a prophylactic against the poisonous effects of lead, the habitual use, internally and externally, of dilute sulphuric acid. (See *Plumbum.*)

Carbonate of lead is used pharmaceutically by the British Colleges for obtaining acetate of lead.

OXIDUM PLUMBI RUBRUM. *Ed.*

Red Oxide of Lead.

Red lead, Minium; Deutoxide de plomb, Minium, *Fr.;* Menning, *Germ.;* Minio, *Ital., Span.*

Preparation. Red lead is prepared on the large scale in a furnace, with the floor slightly concave and the roof arched, presenting a general resemblance to a baker's oven. The lead is placed on the floor, and gradually raised to a red heat, whereby it melts and becomes covered with a pellicle of protoxide, which is removed by means of a long iron scraper; and the pellicles, as they successively form, are scraped off, until the whole of the metal has been converted into them. The product is subjected to further calcination with occasional stirring, for some time, with a view to oxidize any particles of metallic lead. It is thus rendered yellow, and constitutes the *protoxide of lead*, or *massicot*. This is taken out of the furnace and thrown upon a level pavement, and cooled by being sprinkled with water. It is next reduced to fine powder by trituration and levigation, and dried; and in this state is introduced into large, shallow, square tin boxes, which are placed in another furnace, closed from the air, and heated nearly to redness; the heat being allowed gradually to fall during a period of from twenty-four to thirty hours. At the end of this time the protoxide of lead will have combined with an additional quantity of oxygen, and become the red oxide. This is taken out, and having been passed through a fine wire sieve, is packed in barrels for the purposes of commerce.

The above is an outline of the French process for making red lead. In England and the United States, the calcination of the protoxide is not performed in tin boxes, but by replacing it in the furnace in which it was first calcined. To save the first calcination, litharge is generally used for making the red lead of commerce, which consequently contains the impurities of that substance, consisting of iron, copper, a little silver, and silica. The presence of copper is hurtful in red lead, when used for making glass, to which this metal communicates colour. In order to have red lead of good quality, it is necessary that it be made in large quantities at a time. It is also important that it be slowly cooled; for as the absorption of oxygen by which it is formed, takes place during a particular interval of temperature only, it is necessary that the heat within that interval should be maintained sufficiently long to allow all the protoxide to absorb its appropriate dose of oxygen.

Properties, &c. Red lead is in the form of a heavy, scaly powder, of a bright red colour, with a slight shade of orange. Its sp. gr. is about 9. When exposed to heat it gives off oxygen, and is reduced to the state of protoxide. It is sometimes adulterated with red oxide of iron, or red bole, substances which may be detected by dissolving the suspected red lead in nitric acid, and testing with tincture of galls. This reagent will produce a black precipitate, in consequence of the iron present in the substances mentioned. If powdered brick be present, it will be left undissolved upon treating the suspected specimen with muriatic acid. When free from impurities, it is completely reduced on charcoal, by means of the blowpipe, into a globule of metallic lead. When treated by nitric acid, it is resolved into protoxide which dissolves, and peroxide which remains insoluble.

The red lead of commerce may be considered as a mixture of what may be called the true red oxide, and variable proportions of protoxide. That this is its nature is proved by the action of cold dilute acetic acid, not used in excess, which takes up a variable quantity of protoxide, leaving a portion unchanged in colour, which may be deemed the pure red oxide. This latter, when analyzed by nitric acid, has been proved, by the coincident results of Dalton, Dumas, and Phillips, to consist of two equiv. of protoxide, and one of peroxide, corresponding with three equiv. of lead, and four of oxygen. (*Journ. of Phil. Col. of Pharm.* vi. 162, from *Phil. Mag. N. S.* iii. 125.)

Medical Properties and Uses. Red lead is officinal only with the Edinburgh College, and is employed exclusively as an external application, entering into the composition of some unofficinal ointments and plasters. Its chief use is in the arts, as a paint and as an ingredient in flint glass. B.

PLUMBI OXIDUM SEMIVITREUM. *U.S.*

Semivitrified Oxide of Lead.

Off. Syn. PLUMBI OXYDUM SEMIVITREUM. *Lond.;* OXIDUM PLUMBI SEMIVITREUM. *Ed.;* PLUMBI OXYDUM SEMIVITREUM. LITHARGYRUM. *Dub.*

Oxide de plomb fondu, Litharge, *Fr.;* Lithargyrus, *Lat.;* Bleiglätte, *Germ.;* Litargirio, *Ital.;* Almartaga, *Span.*

When the protoxide of lead is rendered crystalline by fusion, it becomes the semivitrified oxide, or litharge. Almost all the litharge of commerce is obtained in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is calcined in the open air; whereupon the lead becomes oxidized, and by fusion passes into the state of litharge, while the silver remains behind. The following is an outline of the process.

Preparation. The lead containing the silver is placed upon an oval slightly excavated dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone-earth formed into a paste with water, into a mould, the sides of which are formed of an elliptical band of iron, and the bottom, of strips of sheet iron, placed a little distance apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed, and adjusted at the level of the floor. On one side of the test the fire-place is situated, and exactly opposite, the chimney; while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the centre of the test. The furnace is now lighted, and shortly afterwards, the bellows is put in motion. The lead fuses and combines with oxygen, and the resulting oxide melting also, forms a stratum which swims on the surface, and which is driven by the wind of the bellows along the gutter, and through the vertical hole, into a recipient below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and driven off the test, fresh portions are added, so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test; and the oxidizement proceeding, a period at last arrives when the whole of the lead has run off as litharge, and the silver, presenting a very brilliant appearance, alone remains. This is then removed, and the process repeated on a fresh portion of argentiferous lead.

Properties. Litharge is in the form of small, brilliant, vitrified scales, some presenting a red, and some a yellow colour. It is devoid of taste or smell. It slowly attracts carbonic acid from the air, and contains more of this acid the longer it has been prepared. It is on this account that it effervesces with the stronger acids. As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. The English litharge is most esteemed; that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper and from fragments of vegetable matter. This metal is detected, if upon adding ferrocyanate of potassa to a nitric solution of the litharge, a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their colour, and dependent on differences in the mode of manufacture. Sometimes it has a pale yellow colour and silvery appearance, and is then denominated *litharge of silver*, or *yellow litharge;* at other times it is of a red colour, and is known under the name of *litharge of gold*, or *red litharge*. In composition, litharge is essentially identical with the protoxide of lead. (See *Plumbum*.) The carbonic acid which it contains is variable, dependent on the length of time it has been prepared; but its average amount is about four per cent.

Pharmaceutical Uses, &c. Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, which are used for abating inflammation, and for other purposes. Combined with olive oil it forms the *Emplastrum Plumbi*, which is the basis of a majority of the preparations technically called *Plasters*. (See *Emplastra*.) In the arts it is extensively employed in the glazing of pottery, in painting to render oils drying, and as an ingredient in flint glass.

◆

PODOPHYLLUM. *U.S.*

May-apple.

"Podophyllum peltatum. Radix. *The root.*" *U.S.*

Podophyllum. *Sex. Syst.* Polyandria Monogynia.—*Nat. Ord.* Ranunculi, *Juss.;* Podophylleæ. *Lindley.*

Gen. Ch. Calyx three-leaved. *Corolla* nine-petaled. *Berry* one-celled, crowned with the stigma. *Willd.*

Podophyllum peltatum. Willd. *Sp. Plant.* ii, 1141; Bigelow, *Am. Med. Bot.* ii. 34; Barton, *Med. Bot.* ii. 9. The may-apple, known also by the name of *mandrake*, is an indigenous herbaceous plant, and the only species belonging to the genus. The root is perennial, creeping, usually several feet in length, about one quarter of an inch thick, of a brown colour externally, smooth, jointed, and furnished with radicles at the joints. The stem is about a foot high, erect, round, smooth, divided at top into two petioles, and supporting at the fork a solitary one-flowered peduncle. Each petiole bears a large peltate, palmate leaf, with six or seven wedge-shaped lobes, irregularly incised at the extremity, yellowish-green on their upper surface, paler and slightly pubescent beneath. The flower is nodding. The calyx is composed of three oval, obtuse, concave, deciduous leaves. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong yellow anthers of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow colour, interrupted by round brownish spots.

The plant is extensively diffused throughout the United States, growing luxuriantly in moist shady woods, and in low marshy grounds. It is propagated by its creeping root, and is often found in large patches. The flowers appear about the end of May and beginning of June; and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its colour and shape it is sometimes called *wild lemon.* The root is the officinal portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

Properties. The dried root is in pieces about two lines in thickness, with swelling, broad, flattened joints at short intervals. It is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with fibres of a similar, but somewhat paler colour. The fracture is short and irregular, and the internal colour whitish. The powder is light yellowish-gray, resembling that of jalap. The root in its aggregate state is nearly inodorous; but in powder has a sweetish not unpleasant smell. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. The docoction and tincture are bitter. A peculiar bitter principle has been discovered in the root by William Hodgson, jun. of Philadelphia. It is in pale brown shining scales, unalterable in the air, very sparingly soluble in cold water, much more soluble in boiling water, soluble also in ether, and freely so in boiling alcohol. It has neither acid nor alkaline properties. Nitric acid dissolves it with effervescence, producing a rich deep red colour. Its taste, at first not very decided in consequence of its feeble solubility, becomes at length very bitter and permanent; and its alcoholic solution is intensely bitter. Should it be found to be the purgative principle of the plant, it would be entitled to the name of *podophyllin.* It may be obtained by boiling the root with quicklime in water, straining the decoction, precipitating the lime with sulphate of zinc, evaporating the clear solution to the consistence of an extract, treating this with cold alcohol of 0.817, filtering and evaporating the alcoholic solution, and treating the residue with boiling distilled water, which deposites the bitter principle on cooling. (*Journ. of the Phil. Col. of Pharm.* iii. 273.)

Medical Properties and Uses. Podophyllum is an active and certain cathartic, producing copious liquid discharges without much griping or other unpleasant effect. In some cases it has given rise to nausea and even vomiting, but the same result is occasionally experienced from every active cathartic. Its operation resembles that of jalap; but is rather slower, and is thought by some to be more drastic. It is applicable to most inflammatory affections which require brisk purging; and is much employed in various parts of the country, especially combined with calomel, in bilious fevers and hepatic congestions. It is also frequently used in connexion with the supertartrate of potassa in dropsical, rheumatic, and scrofulous complaints.

The dose of the powdered root is about twenty grains. An extract is prepared from it possessing all its virtues in a smaller bulk. (See *Extractum Podophylli.*) In minute doses frequently repeated, podophyllum is said to diminish the frequency of the pulse, and to relieve cough; and for these effects is sometimes used in hæmoptysis, catarrh, and other pulmonary affections.

POLYGALA RUBELLA. *U.S. Secondary.*

Bitter Polygala.

"Polygala rubella. Planta. *The plant.*" *U.S.*

Polygala. See SENEGA.

Polygala rubella. Willd. *Sp. Plant.* iii. 875; Bigelow, *Am. Med. Bot.*

iii. 129.—*P. polygama.* Walter, *Flor. Car.* 179; Pursh, *Flor. Am. Sept.* 465. This species of Polygala is an indigenous, perennial plant, with a branching, somewhat fusiform root, which sends up annually numerous simple, smooth, and angular stems, from four to eight inches in height. The leaves are scattered, sessile, obovate or linear lanceolate, attenuated towards the base, obtuse, and mucronate. The flowers are purple, and in elongated terminal racemes. From the base of the stem proceed other racemes, which lie upon the ground, or are partially buried under it, and bear incomplete but fertile flowers, the calyx of which is without wings.

This plant is found in many parts of the United States, preferring a dry sandy or gravelly soil, and flowering in June and July. The whole plant is officinal. It has a strong and permanent bitter taste, which it yields to water and alcohol.

Medical Properties and Uses. In small doses it is tonic, in larger laxative and diaphoretic. The infusion of the dried plant has been usefully employed to impart tone to the digestive organs. (*Bigelow.*) It appears to be closely analogous in medical virtues to the *Polygala amara* of Europe, which is used for a similar purpose. W.

PORRI RADIX. *Lond.*

Leek Root.

"Allium Porrum. *Radix.*" *Lond.*

Poireau, *Fr.;* Gemeiner Lauch, *Germ.;* Porro, *Ital.;* Puerro, *Span.*

Allium. See ALLIUM.

Allium Porrum. Willd. *Sp. Plant.* ii. 64. "Stem flat-leaved, umbelliferous. Stamens tricuspidate. Root tunicated."

The leek is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive pungent odour, and an acrid taste, dependent on an essential oil, which is in great measure dissipated by decoction, and may be obtained separate by distillation. The bulb, which is the officinal portion, consists of concentric layers, like the onion, which it resembles in medical properties, though somewhat milder. It is gently stimulant, with a peculiar direction to the kidneys. The expressed juice may be given in the dose of a fluidrachm, mixed with syrup. This species of Allium is not used medicinally in the United States. W.

POTASSIUM.

Potassium.

Potassium, *Fr.;* Potassium, Kalimetall, *Germ.;* Pottasio, *Ital.;* Potasio, *Span.*

Potassium is a peculiar metal forming the basis of a number of importan medicinal preparations. It was discovered iu 1807 by Sir H. Davy, wh obtained it by the agency of galvanic electricity; but it is procured mor readily by heating the hydrate of potassa to whiteness in contact with iro or charcoal, whereby the alkali is decomposed, yielding up its oxygen to th iron or charcoal, while its metallic radical is set free.

Potassium is solid, softer and more ductile than wax, easily cut with knife, and of a silver-white colour. A newly cut surface is exceedingl brilliant; but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from every other substance. On account of this property it requires to be kept in liquids, such as naphtha, which are devoid of oxygen as a constituent. Its sp. gr. is between 0.8 and 0.9, its melting point 136°, and its equivaleut number 39.15. When thrown upon water it swims, takes fire, and burns with a rose-coloured flame, combining with oxygen, and generating potassa which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic bodies, and several of the metals. It combines in two proportions with oxygen, forming a protoxide (dry potassa) of a gray, and a peroxide, of a yellowish-brown colour; the former containing one, and the latter three equivalents of oxygen to one of metal. It combines also with chlorine and iodine, forming the chloride and iodide of potassium, the latter of which is officinal. Its protoxide (dry potassa) is a very strong salifiable base, existing in nature always in a state of combination, and forming with acids a numerous and important class of salts. Of these, the acetate, carbonate, bicarbonate, hydrate (caustic potassa), nitrate, sulphate, supersulphate, tartrate, and supertartrate are officinal, and will be described under their respective titles, to which, for their properties, the reader is referred. B.

POTASSÆ ACETAS. *U.S., Lond., Dub.*

Acetate of Potassa.

Off. Syn. ACETAS POTASSÆ. *Ed.*

Diuretic salt, Foliated earth of tartar, Digestive salt of Sylvius; Acétate de potasse, *Fr.;* Essigsaures Kali, *Germ.;* Acetato di potasso, *Ital.*

Acetate of potassa is included among the preparations in the Pharmacopœias of the British Colleges; but is perhaps more properly placed in the catalogue of the Materia Medica in the United States Pharmacopœia.

Preparation, &c. This salt is prepared by saturating a filtered solution of carbonate of potassa with distilled vinegar or acetic acid, and heating the mixture to assist the disengagement of the carbonic acid. An excess of acid is now added, which prevents the potassa from colouring the solution by acting on any small portion of mucilage which may exist in the acid. The solution is then evaporated to three-fourths, care being taken to maintain its excess of acid. It is now somewhat coloured, and being allowed to cool, and to remain at rest for some hours, is afterwards decanted. The decanted liquid is next mixed with a fifth of its weight of animal charcoal, boiled for a few moments and filtered; after which it is evaporated to a pellicle. The concentrated solution is next evaporated to dryness, in separate small portions, in a shallow silver capsule, with a moderate fire. As the pellicles form on the surface, they are constantly scraped off to the edges of the capsule, and the heat is continued until the whole is converted into these pellicles. The desiccation being completed, the capsule is covered with paper; and its contents, when cool, are transferred to a perfectly dry bottle, which must be well stopped.

The above process is merely a case of single elective affinity, the acetic acid combining with the potassa, and expelling the carbonic acid, which causes the effervescence. This salt may be obtained also by double decomposition between acetate of lead and sulphate of potassa. When thus procured, it is very white and pure, but liable to the objection, for medical use, that it may possibly contain lead. Another method by double decomposition is between the acetate of lime and sulphate of potassa; but when thus prepared, the salt is apt to contain some of the alkaline sulphate.

The following is an outline of the processes adopted by the British Colleges for obtaining this salt. The London College uses the stronger acetic acid, obtained by purifying pyroligneous acid, for decomposing the carbonate of potassa, and directs the evaporation of the solution to be conducted in such a manner as to convert the whole into successive pellicles. The Edinburgh and Dublin Colleges direct distilled vinegar and the carbonate of potassa from tartar for making the salt; and after subjecting it to exsiccation and cautious fusion, redissolve it in water, filter the solution and evaporate it to such an extent that it may concrete into a crystalline mass upon cooling.

Properties. Acetate of potassa when pure, is a white salt, possessing a pungent saline taste, which diffuses a peculiar warmth over the palate. When unskilfully prepared, it is apt to be more or less coloured; and as there is some difficulty in obtaining it free from colour, the different processes for preparing it are particularly directed to attaining this object. Its state of aggregation differs with the manner in which it has been prepared. When obtained by removing the pellicles from the solution of the salt as it evaporates, it is in the form of light, white, spongy masses; when by concretion upon the cooling of the concentrated solution, it presents a flaky or foliated texture. The latter form is that in which it is generally found in our shops. This salt is extremely deliquescent, and if exposed to the air becomes converted into a liquid of an oleaginous appearance. It is on account of this property that it must always be preserved in well stopped bottles. It dissolves in about half its weight of water, and twice its weight of alcohol. Exposed to a high temperature it fuses, and, upon slow cooling, assumes the form of a foliated mass. If the heat be continued, it is decomposed, and resolved into water, oil, and ammonia, which are volatilized, and carbonate of potassa with charcoal, which remains as a fixed residue. When treated with sulphuric acid, acetic acid is set free, and sulphate of potassa formed. The most usual impurities which it contains are the sulphate and tartrate of potassa, and the salts of lead and copper. The presence of a soluble sulphate will be shown by nitrate of baryta producing a precipitate. If tartrate of potassa be present, the salt will not be entirely soluble in alcohol. Lead and copper may be detected by sulphuretted hydrogen and ferrocyanate of potassa; the former test producing with the lead a blackish, and the latter with the copper a brown precipitate.

Acetate of potassa is not unfrequently a constituent in organic substances. According to Vauquelin, it is present in the sap of nearly all trees; and it has been detected in some animal fluids, as in milk.

Incompatibles. This salt is decomposed by sulphuric, muriatic, and nitric acids, acetic acid being expelled. It is incompatible also with the sulphates of soda and magnesia, the muriates of ammonia and magnesia, the tartrate of potassa and soda (Rochelle salt), the corrosive chloride of mercury, nitrate of silver, and several other metallic and earthy salts.

Composition. It consists of one equivalent of acetic acid 51.48, one of potassa 47.15, and two of water 18 = 116.63.

Medical Properties and Uses. Acetate of potassa acts as a diuretic in doses of from a scruple to a drachm, and as a mild cathartic when given to the extent of two or three drachms. It is employed in dropsies, and often with good effect. The late Dr. Duncan considered it to be a medicine of great efficacy, and one of the best saline deobstruents that we possess. We have ourselves used it in dropsical affections, and can bear testimony to its powers. The acetate, ready prepared, being an expensive preparation, the salt, equally efficacious, may be made extemporaneously in the liquid form by saturating distilled vinegar with the carbonate of potassa. Two drachms of the carbonate saturated with vinegar, will sometimes produce in hydropic cases ten or twelve stools, and a copious discharge of urine. (*Duncan.*) Acetate of potassa, like the other alkaline salts containing a vegetable acid, may be given in the uric acid diathesis, to *alkalize* the urine; for the experiments of Wöhler have shown that the acid of these salts undergoes decomposition in the digestive and assimilating processes, while the alkali enters the current of the circulation.

Acetate of potassa is used pharmaceutically for obtaining acetic acid by the Dublin College, and in the preparation of acetate of mercury, the tinctures of acetate of iron, and the tincture of acetate of zinc. It enters into no officinal preparation.

B.

POTASSÆ CARBONAS IMPURUS. *U.S.*

Impure Carbonate of Potassa.

Off. Syn. POTASSA IMPURA. *Lond.;* SUB-CARBONAS POTASSÆ IMPURUS, *Ed.;* LIXIVUS CINIS. *Dub.*

Pearlash, Pearlashes, Impure potassa, Impure sub-carbonate of potassa; Potasse du commerce, *Fr.;* Kohlensaures Kali, Pottasche, *Germ.;* Potasch, *Dutch.;* Potaske, *Dan.;* Potaska, *Swed.;* Potassa del commercio, *Ital.;* Cenizas claveladas, *Span.*

The alkali potassa, using this term in its strict sense, is the protoxide of the metal potassium. (See *Potassium.*) It exists in various states of combination and of purity. In its most impure state, it is the common *potash* of commerce. This, subjected to calcination, becomes somewhat purer, and is called *pearlash*, the form of the alkali which is intended to be designated by the officinal name at the head of this article.

Natural State and Preparation. Potash and pearlash of commerce are rocured from the ashes of wood, by lixiviation and the subsequent evapo-ation of the solution obtained. The alkali exists in the wood, principally in he state of acetate; and being of a fixed and incombustible nature, is left ehind after the incineration. The wood is burnt on the ground, in a place heltered from the wind. The ashes which are left, consist of a soluble nd insoluble portion. The soluble part is made up of carbonate of potassa, ogether with the sulphate, phosphate, and silicate of potassa, and the chlo-ides of potassium and sodium; and the insoluble portion, of carbonate and ubphosphate of lime, alumina, silica, the oxides of iron and manganese, and little carbonaceous matter that had escaped incineration. The ashes are xiviated in barrels with the addition of a portion of lime, and the soluble sub-tances above mentioned are taken up. The lixivium is then evaporated in on kettles, which for several days are constantly kept full. The evapora-on is continued until the mass has become of a black colour, and of the nsistence of brown sugar. It is now subjected to as powerful a heat as n be raised by the best wood fire for a number of hours. During the rogress of the fusion, the combustible impurities are for the most part de-royed, and a gaseous matter is emitted, which agitates the more fluid part. Vhen the fusion is complete, the liquid becomes quiescent, and looks like melted iron. It is now transferred, by means of large iron ladles, to iron pots, where it congeals in cakes. These are broken up into fragments and packed in tight barrels, and constitute the *potash* of commerce. (*Dr. G. A. Rogers*, in Silliman's Journ.) If it be intended to make *pearlash*, the process is different. In this case the black matter of the consistence of brown sugar, (called *black salts* by our manufacturers,) instead of being fused, is transferred from the kettles to a large oven-shaped furnace, so constructed that the flame is made to play over the alkaline mass, which in the meantime is stirred by means of an iron rod. The ignition is in this way continued, until the combustible impurities are burnt out, and the mass, from being black, becomes of a dirty white colour. (*Rogers.*)

The ashes of plants amount generally to not more than a few parts in the hundred; and of these, only a portion consists of carbonated potassa. The different parts of the same vegetable, and, for a stronger reason, different plants, furnish variable quantities of ashes. Ligneous plants furnish less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the interior portions; and the leaves of trees which drop their leaves in winter, more than those of evergreens. The dried stems of potatoes have been said to yield the impure carbonate of potassa, to the extent of five and a half per cent.; but this statement has not been confirmed. The ashes of the poke contain a large proportion of this alkali. (See *Phytolaccæ Baccæ et Radix.*) The pine, on the contrary, contains nearly no potash.

Commercial History. Pot and pearlash are made in those countries in which forests abound. Accordingly the alkali is extensively manufactured in Canada and the United States, and constitutes a very important export of this country. It is prepared particularly in the state of New York, which is supposed to furnish three-fourths of our export of this alkali. It is also produced in considerable quantities in the northern countries of Europe, especially in Russia, and on the shores of the Baltic. It is of different qualities as it occurs in commerce, being more or less pure; and is generally distinguished by the country or place of manufacture, as *American*, *Russian*, *Dantzic* potash, &c.

Properties. Potash is in the form of fused masses of a stony appearance and hardness, and caustic burning taste. Its colour is variegated; but reddish and dark brown are the predominant hues. When exposed to the air it absorbs moisture, and deliquesces; and if sufficiently long exposed, finally becomes liquid. *Pearlash* is of a white colour, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire hard concrete mass. In the shops it is found in coarse powder, intermingled with lumps, as dug out of the casks, presenting an opaque granular appearance, like salt, or Havana sugar. It is a deliquescent salt, and has a burning alkaline taste, but no smell. It is soluble in water, with the exception of impurities, which are more or less in quantity, according to the quality of the alkali, of which three sorts exist in the market. It differs from potash principally in containing less combustible impurities and in being less caustic and deliquescent, and commands in the market from five to fifteen dollars per ton more than potash. The colouring matter of both these forms of alkali is derived from carbonaceous impurities, and small portions of iron and manganese.

Composition. The basis of both pot and pearlash is carbonate of potassa; but this is associatad with certain salts, the principal of which are sulphate of potassa and chloride of potassium, and with insoluble impurities.

Several varieties of potash found in commerce were analyzed by Vauquelin, whose results are contained in the following table. The quantity examined of each kind was 1152 parts.

KINDS OF POTASH.	Caustic Hydrate of Potassa.	Sulphate of Potassa.	Chloride of Potassium.	Insoluble Residue.	Carbonic Acid and Water.
American potash.	857	154	20	2	119
Russian potash.	772	65	5	56	254
Pearlash.	754	80	4	6	308
Potash of Trèves.	720	165	44	24	199
Dantzic potash.	603	152	14	79	304
Potash of Vosges.	444	148	510	34	16

By the above table it is perceived, that the American potash contains the most alkali, and next the Russian. Pearlash, it is seen, is more rich in carbonic acid than potash; and this result of analysis corresponds with the qualities of the two substances as prepared in the United States; potash being known to be far more caustic than pearlash. The greater causticity of the American potash, compared with most of the varieties of Europe, probably depends upon the use of lime with us, which is not mentioned as being employed in the preparation of the commercial alkali in the best European works. The usual saline impurities are shown by the table to be sulphate of potassa and chloride of potassium. The insoluble residue consists principally of carbonaceous matter, which has escaped incineration. Sometimes, however, insoluble matters are fraudulently added, such as brick-dust, sand, and other substances.

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it becomes important, in so variable a substance, to possess an easy method of ascertaining its quality in that respect. The process by which this is accomplished is called *alkalimetry*, and the instrument used an *alkalimeter*. The best mode of conducting the assay, which is applicable to the commercial forms of soda as well as those of potassa, is that proposed by Mr. Faraday, and described by Dr. Turner as follows. Take a cylindrical tube, sealed at one end, nine and a half inches long, and three quarters of an inch in diameter, and pour into it one thousand grains of water, marking with a file the point at which the water stands. Divide the space occupied by the water into one hundred equal parts, graduating from above downwards; and opposite to the numbers 23.44, 48.96, 54.63, and 65 severally, write the words soda, potassa, carbonate of soda, and carbonate of potassa. Then prepare a dilute sulphuric acid, having the specific gravity 1.127, which may be formed by adding to the strong acid, about four times its volume of distilled water. An acid of this strength, if added so as to reach to any one of the heights denoted by the above numbers, will be just sufficient for neutralizing one hundred grains of the alkali written opposite to it. Suppose, for example, that the dilute acid be added until it stands opposite to the word carbonate of potassa, we shall then have the exact quantity necessary to neutralize one hundred grains of that carbonate; and if we add pure water, until the liquid reaches to 0, or the beginning of the scale, it is evident that the acid has been brought to the bulk of a hundred measures, each of which would be competent to neutralize one grain of the carbonate in question. All that is now necessary in order to ascertain the quality of any commercial sample of this carbonate, is to dissolve one hundred grains of it in warm water, filter the solution to remove insoluble impurities, and add by degrees the dilute acid from the tube until the solution is exactly neutralized, as shown by litmus paper. The number of divisions of acid expended in attaining this point, may be read off from the tube; and for each division one grain of real carbonate is indicated.

Pharmaceutical Uses. Pearlash is never used as a medicine in regular practice, being considered as too impure; but it is employed pharmaceutically in several processes. The Dublin College uses it for depriving rectified spirit of water, in the process for strengthening it; and it is directed to be purified, in all the Pharmacopœias, to form the carbonate of potassa.

* * *

POTASSÆ NITRAS. *U.S.*, *Lond.*, *Dub.*

Nitrate of Potassa.

Off. Syn. NITRAS POTASSÆ. *Ed.*

Nitre, Saltpetre; Nitrum, *Lat.;* Nitrate de potasse, Azotate de potasse, Nitre, Saltpêtre, *Fr.;* Salpeter-saures Kali, Salpeter, *Germ.*, *Dutch*, *Dan.*, *Swed.;* Nitro, *Ital.*, *Span.*, *Port.*

Nitre or saltpetre is both a natural and artificial production. It is found ready formed in many countries, existing in the soil on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in Egypt, and in Peru; but the country in which it is most abundantly produced is India, from which the principal part is furnished for the demands of commerce. The value of our imports of crude saltpetre from India for 1832 exceeded four hundred thousand dollars. In the United States it is found in Georgia, Tennessee, Virginia, Maryland, Ohio, and Kentucky. It exists, in these States, for the most part in caverns situated in limestone rock, called saltpetre caves, and is associated with nitrate of lime. The earths contained in them are lixiviated, and yield, according to their richness, from one to ten pounds of crude nitre to the bushel. These caves are particularly numerous in Kentucky, and furnished a large portion of the nitre consumed in the United States during the late war. It exists also in the vegetable kingdom, having been found in borage, tobacco, bugloss, parietaria, hemlock, and the sunflower. The artificial sources of nitre are certain mixtures of animal and vegetable substances with wood-ashes and calcareous matter, called nitre beds; and certain materials, impregnated with saltpetre, consisting principally of old plaster, derived from the demolition of old buildings.

Preparation from its Natural Sources. In India the soil of the nitre districts is lixiviated, and the lixivium obtained evaporated in shaded shallow pits, until it crystallizes. Where the material is less rich in nitre, and contains nitrate of lime, as is the case with the earths from our saltpetre caves, it is necessary to convert the latter salt into nitrate of potassa by the addition of wood-ashes.

Artificial Preparation. The plan of forming saltpetre in artificial nitre-beds is principally practised in Germany; while the method of obtaining it from old plaster rubbish is followed in France. *Artificial nitre-beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter them from the rain; while the sides are left open to permit the free access of air. The matter is disposed in little ranges or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, uniting with the potassa existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown colour, and contains chiefly the nitrate of potassa, but at the same time more or less of the nitrates of lime and magnesia, and of common salt. The earthy nitrates are then decomposed by a solution of wood-ashes, which, by furnishing potassa, converts them into nitre, and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The solution is then allowed to cool, and the nitre crystallizes in dirty white crystals, called crude nitre.

When obtained from old plaster rubbish, the material is reduced to powder and lixiviated, in order to exhaust it of every thing soluble. The solution is found to contain the nitrates of potassa and lime, and common salt, and is treated with wood-ashes, which convert the nitrate of lime into nitrate of potassa, with precipitation of the earth as a carbonate. The liquor is separated from the precipitate and concentrated by heat; and the common salt as it rises to the surface is skimmed off. When the solution is so strong as to mark 45° of Baumé's areometer, it is allowed to cool and crystallize; and the crystals form the crude nitre of this process. The salt obtained in this way generally contains from 85 to 88 per cent. of pure nitre; the remainder being made up of chloride of sodium, and certain deliquescent salts. The details of the above process as practised in Paris, are given with minuteness by Thenard. (*Traité de Chimie, sixième édit.* 1834, tome iii. p. 340.

Purification. Nitrate of potassa, as first obtained, either from its natural or artificial sources, is called in commerce *crude saltpetre*, and requires to be purified or refined before it can be used in medicine or in most of the arts. The process, which is founded principally on the fact of the greater solubility of nitre than of common salt in hot water, is conducted in the following manner in France. Thirty parts of the saltpetre are boiled with six parts of water, and the portion which remains undissolved, or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added at intervals, until the whole amounts, including that previously added, to ten parts. The clear solution is now transferred to large, shallow, copper coolers, where it is agitated with wooden instruments, to hasten the cooling, and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper, with holes in its bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, at the end of which time it is permitted to drain off by taking out the pegs. The salt being now dried, its purification is completed.

In Sweden, the process of purification is somewhat different. The solution of the crude nitre is boiled, until a saline crust (common salt) forms on its surface, and until it is so far concentrated that a small portion of it crystallizes upon cooling. The crust being removed, the solution is filtered, and diluted with 1-48th of water, with a view to retain in solution the common salt, which, being somewhat less soluble in cold than in boiling water, would otherwise be in part precipitated on refrigeration. The solution is now allowed to cool, and, at the moment crystals begin to form, is stirred constantly to cause the salt to crystallize in small grains. The granular salt is then washed after the French method, as above described, dried, and being fused, is cast in sheet iron moulds, so as to form masses, each weighing from ten to twenty pounds. The preparation of nitre in this manner by fusion is, according to Berzelius, attended with several advantages; such as its occupying less space, its losing nothing by waste in transportation, and its presenting in this state an obvious index of its quality. This index is the character of its fracture. When the salt is perfectly pure, this is radiated, the radii being generally large. The presence of 1-80th of common salt renders the radii smaller; and of 1-40th or a larger quantity, produces a zone in the substance of the mass, devoid of the radiated structure, or causes this structure to disappear entirely. On the other hand, the process by fusion has the disadvantages of converting the salt in part into nitrite when heated too high, and of rendering it difficult to pulverize.

Commercial History. Nitre is received in this country from Calcutta in the state of crude saltpetre, packed in grass cloth bags, containing from one hundred and fifty to one hundred and seventy-five pounds. The greater portion of it arrives at Boston, which city carries on a very brisk trade with Calcutta. Its quality varies considerably. That which comes in dirty yellow crystals is called *crude saltpetre;* while the finer lots, in small, comparatively clear crystals, approaching to white, are called *East India refined.* Very little crude saltpetre is at present prepared in the United States, on account of the low price of that from India, which for the average of the few last years has been only seven and a half cents a pound. The *refined saltpetre* is almost exclusively prepared by our own chemists; and a considerable portion of it is exported.

As connected with the subject of saltpetre, it may be proper, in this place, to mention what is called *South American saltpetre*, considerable quantities of which have been received within a few years from Peru. This substance is the *nitrate of soda*, and comes in bags containing about two hundred and seventy pounds of the salt in the crude state. This salt is coming into use with our manufacturing chemists, and is better suited than nitre for preparing nitric and sulphuric acids, on account of the greater proportional quantity of acid which it contains. It is, however, not applicable to the purpose of making gunpowder, from its tendency to absorb moisture.

Properties. Nitre is a white salt, possessing a sharp, cooling, and slightly bitterish taste, and generally crystallized in long, striated, semitransparent, six-sided prisms, with dihedral summits. It dissolves in four or five times its weight of cold, and in about two-fifths of its weight of boiling water; but is insoluble in absolute alcohol. It undergoes no alteration in the air, unless this be very moist. It contains no water of crystallization; but is apt to hold a portion of liquid, mechanically lodged within the substance of the crystals. This is particularly the case with the *large* crystals, and, according to Berzelius, is a source of impurity; as the liquid in question is a portion of the mother-waters in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be made by agitation to shoot into *small* crystals. When exposed to heat, nitre fuses at about 662°. (*Thenard.*) The fused mass, when cast in moulds, or forme into little circular cakes, constitutes that form of nitre kept in the shops under the name of *crystal mineral* or *sal prunelle.** If the heat be increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of a nitrite. Upon a further continuance of the heat, the nitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. The residuum, after the gaseous matter has ceased to come over, is, according to Berzelius, a compound of potassa with nitric oxide; but, sometimes at least, it is the peroxide of potassium, as was observed about the same time by Mr. Phillips of London and Dr. Bridges of Philadelphia. On account of the large quantity of oxygen which it contains, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coals, it deflagrates with bright scintillations. Mixed with half its weight of sulphur, and two-thirds of its weight of pearlash, it forms a compound, powerfully detonating when struck with a hammer. Nitre may be readily recognised by its effect in increasing the combustion of live coals, when thrown upon them; and by evolving white or reddish vapours on the affusion of sulphuric acid. When fused, its radiated structure is a test of its purity. Its most usual impurity is common salt, which injures its quality for the manufacture of gunpowder. The presence of this contaminating salt is readily detected by nitrate of silver. The refined or purified saltpetre of commerce may be deemed the officinal nitre, and is sufficiently pure for medical use. Nevertheless, the Dublin College, with needless refinement, has given a formula for its purification. (See *Potassæ Nitras Purificatum*, Dub.)

Composition. Nitrate of potassa is composed of one equiv. of nitric acid 54.15, and one of potassa 47.15=101.3.

Medical Properties and Uses. Nitre is considered refrigerant and antiphlogistic, and is much used in inflammatory diseases. It is known to be a powerful antiseptic. It generally promotes the secretion of urine and sweat, lessens the heat of the body and the frequency of the pulse, and has a tendency to keep the bowels in a soluble condition. It is very frequently prescribed with tartar emetic and calomel, forming a combination usually called the *nitrous powder*, which promotes most of the secretions, particularly those of the liver and skin, and which in many cases is advantageously employed in lessening and modifying febrile excitement. The formula usually preferred is eight or ten grains of nitre, the eighth of a grain of tartar emetic, and from a fourth to half of a grain of calomel, exhibited every two or three hours. Nitre is frequently given in active hemorrhages, particularly hæmoptysis, and is useful as an ingredient in gargles, in certain stages of inflammatory sore-throat. In the form of sal prunelle, it is rubbed with advantage on chapped lips. The dose is from five to fifteen grains, dissolved in water or some mucilaginous fluid, and repeated every two or three hours. From one to three drachms may, in this manner, be exhibited in the course of the day. If given too freely, or for too long a period, it is apt to excite pains of the stomach. In an over-dose, (half an ounce to an ounce or more,) sometimes taken by mistake for sulphate of soda, it causes violent symptoms; such as intense pain in the stomach, vomiting and purging of blood, great prostration, convulsions, and sometimes death. On dissection, the stomach and intestines are found violently inflamed. The treatment in such cases consists in the administration of mucilaginous and demulcent drinks, laudanum to allay pain and irritation, and cordials in the sinking condition of the system.

---

* The *sal prunelle*, as made in France, is a mixture of nitrate and sulphate of potassa. It is prepared by fusing a pound of pure nitre in a Hessian crucible, and throwing into the fused salt a drachm of pulverized sulphur. The sulphur immediately takes fire, and by combining with oxygen from the nitre, becomes sulphuric acid, which then combines with the potassa of this salt, and forms sulphate of potassa. The mixed salts are then poured into a heated silver basin, where they are allowed to congeal in thin layers. This preparation is said to be called sal prunelle, because formerly it was the custom to give it a purple colour, resembling that of the plum.

Pharmaceutical Uses, &c. In pharmacy nitre is employed to form crocus of antimony, (see *Edinburgh process for tartar emetic,*) and to obtain nitric acid, (see *Acidum Nitricum,*) sweet spirit of nitre by the United States formula, and purest carbonate of potassa (*salt of tartar.*) It enters into the composition of moxa, (see *Moxa*, Dub.,) and is employed in preparing the sulphate of potassa with sulphur of the Edinburgh College. In the laboratory it is used as an oxidizing agent, and to yield oxygen at a red heat. One pound of it will furnish four hundred and fourteen pints of oxygen, sufficiently pure for experiments of illustration. In the arts, it is employed in the production of aquafortis, the manufacture of sulphuric acid, (see *Acidum Sulphuricum,*) and the fabrication of gunpowder. It is this last use which causes its principal consumption. In domestic economy, it is applied to the purpose of preserving meat, especially beef, to the fibre of which it communicates a red colour and considerable firmness.

◆

POTASSÆ SULPHAS. *U.S., Lond., Dub.*

Sulphate of Potassa.

Off. Syn. SULPHAS POTASSÆ. *Ed.*

Vitriolated tartar; Tartarum vitriolatum, Arcanum duplicatum, Sal de duobus, *Lat.;* Sulfate de potasse, Potasse vitriolée. *Fr.;* Schwefelsaures Kali, Vitriolisirtir Weinstein, *Germ.;* Solfato di potassa, *Ital.*

This salt is placed among the preparations by the Dublin College; in the Materia Medica list, as well as among the Preparations, by the London and Edinburgh Colleges; and in the Materia Medica list only in the United States Pharmacopœia. The latter position is its proper one, as the salt is manufactured for the most part on the large scale.

Preparation. Several chemical processes give rise to sulphate of potassa as a secondary product. Thus it is produced in the distillation of nitric acid from a mixture of nitre with sulphuric acid or the sulphate of iron; in the decomposition of sulphate of magnesia by carbonate of potassa, in forming carbonate of magnesia, and during the combustion of the mixture of nitre and sulphur in the manufacture of sulphuric acid. (See *Acidum Nitricum,* and *Acidum Sulphuricum.*) When nitric acid is obtained by calcining a mixture of nitre and sulphate of iron, the residue consists of peroxide of iron and sulphate of potassa, the latter of which being alone soluble, is separated by means of water, and crystallized from its solution. The residue of the combustion of sulphur and nitre, in making sulphuric acid, is an impure sulphate of potassa mixed with sulphur, and is not purified for use in medicine, but sold to the alum makers; the sulphate of potassa being one of the saline ingredients of that double salt.

The British Colleges agree in obtaining sulphate of potassa from the salt which remains after the distillation of nitric acid. This salt is a supersulphate of potassa, and must be so prepared as to be brought to the neutral state. The London and Dublin Colleges effect this purpose by saturating the excess of acid with carbonate of potassa; the Edinburgh College, by removing the excess by the addition of carbonate of lime, which converts it into an insoluble sulphate of lime. The directions of the London College, which are the most precise, are to dissolve two pounds of the acidulous salt in two gallons of boiling water, to add sufficient carbonate of potassa to saturate the excess of acid, to boil the solution to a pellicle, and, after filtration, to set it aside to form crystals, which, being separated by pouring off the mother-water, are to be dried on blotting paper. Mr. Phillips considers the Edinburgh process to be the best, as it gets rid of the excess of acid; while, by the London and Dublin processes, the additional quantity of sulphate of potassa is obtained by the expenditure of carbonate of potassa, which is of more value than the sulphate. Mr. Brande, however, objects to the Edinburgh formula, that the separation of the sulphate of lime renders it more troublesome, while the saving, by adopting it, is but trifling.

Properties. Sulphate of potassa is a white, anhydrous salt, in the form of small aggregated, transparent, very hard crystals, permanent in the air, having the shape usually of short six-sided prisms, terminated by six-sided pyramids, and possessing a nauseous, somewhat bitter taste. It is slowly soluble in about nine times its weight of cold, and four times its weight of boiling water; but is insoluble in alcohol. When thrown upon burning coals it decrepitates, and exposed to a strong red heat it undergoes fusion. It exists naturally in ligneous vegetables, and hence is present in their ashes. Added to a solution of sulphate of alumina, it generates alum, recognised by the octohedral shape of its crystals. It is decomposed by tartaric acid, which forms bitartrate of potassa, and by the soluble salts of baryta, strontia, lime silver, and lead, forming insoluble, or sparingly soluble sulphates. It consists of one equiv. of sulphuric acid 40.1, and one of potassa 47.15=87.25.

Medical Properties and Uses. Sulphate of potassa is deobstruent and cathartic. In small doses, from a scruple to half a drachm, it operates as an aperient, and is useful in removing obstructions; in larger doses, of four or five drachms, it acts slowly as a gentle purge. Combined with rhubarb, in the proportion of about a drachm of the salt to ten grains of the root, Dr. Fordyce found it an excellent alterative cathartic in the visceral obstructions of children, characterized by a tumid abdomen and defective digestion and nutrition; and we can bear testimony to its efficacy in these cases from our own experience. Dr. A. T. Thomson states that this salt, in combination either with rhubarb or aloes, has proved in his hands "more useful than any of the other saline purgatives, in jaundice and dyspeptic affections." In the arts it is employed in making alum, and by the refiners of saltpetre for converting nitrate of lime into nitrate of potassa.

SUPER-TARTRAS POTASSÆ IMPURUS. *Ed.*

Impure Supertartrate of Potassa.

Off. Syn. TARTARUM. *Lond.*

Crude tartar, Argol; Tartre, *Fr.;* Weinstein, *Germ.;* Tartaro volgare, *Ital.;* Tartaro *Span.*

During the fermentation of acidulous wines, a peculiar matter is deposited on the bottom and sides of the casks, forming a crystalline crust, called *crude tartar*, or *argol*. That deposited from red wine is of a reddish colour, and is called in commerce *red tartar*, while that derived from white wines is of a dirty white colour, and is denominated *white tartar*. Both kinds are essentially the same, consisting of potassa united with an excess of tartaric acid, forming supertartrate (bitartrate) of potassa, mixed with tartrate of lime, more or less colouring matter, together with lees and other matters which are deposited during the clarification of the wine. The substance in question is, therefore, an impure super-tartrate of potassa, as called by the Edinburgh College. When purified it forms the *cream of tartar* of the shops, the *bitartrate of potassa* of the chemist, which is described in the next article.

This acidulous salt exists naturally in the tamarind and grape. In the juice of the latter, it is held in solution by means of the saccharine and mucilaginous matter of the fruit. But when the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is replaced by alcohol, which, not being competent to dissolve the salt, allows it to precipitate. In this way, the deposition of tartar during the fermentation of wine is explained.

Off. Syn. SUPER-TARTRAS POTASSÆ. *Ed.;* POTASSÆ BITARTRAS. TARTARI CRYSTALLI. *Dub.*

Cream of tartar, Crystals of tartar; Cremor tartari, *Lat.;* Tartrate acide de potasse, Crême de tartre, *Fr.;* Doppelt weinsaures Kali, Weinsteinrahm, *Germ.;* Cremore di tartaro, *Ital.;* Cremor de tartaro, *Span.*

Cream of tartar is obtained from crude tartar, the substance described in the preceeding article, by subjecting it to a process of purification. The process is conducted on a large scale at Montpelier in France, and is founded upon the property which cream of tartar possesses, of being much more soluble in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposites, on cooling, a crystalline layer, nearly free from colour. This is redissolved in boiling water; and the solution, having been mixed with four or five per cent. of argillaceous earth, is evaporated to a pellicle. The clay precipitates with the colouring matter, and the clear solution, as it cools, deposites white crystals in crusts, which, upon being exposed to the open air on linen for several days, acquire an increased degree of whiteness. These constitute the crystals of tartar, or cream of tartar of pharmacy. The salt, however, as met with in the shops, is generally, for greater convenience, in the form of powder; and it is to the substance in this form, that we are accustomed to apply the name of *cream of tartar*.

Properties. Supertartrate of potassa occurs in commerce in white crystalline crusts, or masses of aggregated crystals, and is received in that state from France by our wholesale druggists, who procure its pulverization for the use of the apothecaries. In crystals it is hard and gritty under the teeth, and dissolves slowly in the mouth; in powder it has a white colour. It is a permanent salt, having an acid, not ungrateful taste, soluble in sixty parts of cold, and fifteen of boiling water, but insoluble in alcohol. When exposed to heat it is decomposed, exhales a peculiar odour, and gives rise to an acid, called *pyrotartaric*, and the usual products of the destructive distillation of vegetable matter. It is precipitated by solutions of baryta, strontia, and lime, which form insoluble tartrates, and by acetate of lead, forming tartrate of lead. With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral tartrate of potassa, and the tartrate of the base added. Several of them are important medicines, and will be described under their respective heads. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax. The combination thus formed is sometimes used in medicine, and will be described under borax. (See *Sodæ Boras.*)

The cream of tartar of commerce is not a pure supertartrate of potassa. It uniformly contains tartrate of lime, amounting on an average to six per cent., but occasionally even to fourteen per cent. It is sometimes adulterated with sand, clay, and similar substances. The fraud may be easily detected, by treating the suspected salt with a warm alkaline solution, which will dissolve the cream of tartar, and leave the adulterating substances. According to Mr. Brande, purified tartar is sometimes mixed with white siliceous pebbles, bruised into small fragments.

Composition. Cream of tartar consists of two equiv. of tartaric acid 132.96, and one equiv. of potassa 47.15. It is, therefore, in precise chemical language, a *bitartrate of potassa.* When crystallized it contains one equivalent of water, which cannot be expelled without decomposing the salt.

Medical Properties and Uses. Supertartrate of potassa is cathartic, diuretic, and refrigerant. In small doses it acts as a cooling aperient, in large ones as a hydragogue cathartic, producing copious watery stools; and from his latter property, as well as its tendency to excite the action of the kidneys, it is very much used in dropsical affections. When exhibited in these liseases, it is frequently prescribed in combination with jalap. (See *Pulvis Jalapæ Compositus.*) Its solution in boiling water, sweetened with sugar, nd allowed to cool, forms an acid, not unpleasant, refrigerant drink, advanageously used in some febrile affections, and very much employed as a lomestic remedy. The beverage called *imperial* is a drink of this kind, nd is made by dissolving half an ounce of the salt in three pints of boiling vater, and adding to the solution four ounces of white sugar, and half an unce of fresh lemon peel. The dose of cream of tartar is a drachm or two s an aperient; and from half an ounce to an ounce as a hydragogue cathartic, enerally mixed with molasses. As a diuretic in dropsical cases, it is best iven in divided doses to the amount of an ounce or more in twenty-four ours, largely diluted with water.

In pharmacy, cream of tartar is employed in obtaining the neutral tartrate f potassa (soluble tartar), tartrate of potassa and soda (Rochelle salt), tarate of antimony and potassa (tartar emetic), and the tartrate of iron and otassa. Saturated by means of chalk, it forms tartrate of lime, which, ecomposed by sulphuric acid, furnishes tartaric acid. Deflagrated with itre, it is converted into a pure form of carbonate of potassa, called salt of rtar. (See *Potassæ Carbonas Purissimus.*) In the laboratory it is used procure potassa in a pure state, and in making black and white flux. *lack flux* is prepared by deflagrating cream of tartar with half its weight nitre; and *white flux*, by a similar process, using twice its weight of the tter salt.

PRINOS. *U.S. Secondary.*

Black Alder.

"Prinos verticillatus. Cortex. *The bark.*" *U.S.*

Prinos. *Sex. Syst.* Hexandria Monogynia.—*Nat. Ord.* Rhamni, *Juss.*; Ilicineæ, *Brongniart*, *Lindley*.

Gen. Ch. *Calyx* small, six-cleft. *Corolla* monopetalous, subrotate, six-parted. *Berry* six-seeded; seeds nuciform. *Nuttall.*

Prinos verticillatus. Willd. *Sp. Plant.* ii. 225; Bigelow, *Am. Med. Bot.* iii. 141; Barton, *Med. Bot.* i. 203. The black alder is an indigenous shrub, with a stem six or eight feet high, furnished with alternate, spreading branches, and covered with a bluish-gray bark. The leaves, which stand alternately or irregularly on short petioles, are oval, pointed, tapering at the base, acutely serrate, of a dark green colour, smooth on their upper surface, but downy on the veins beneath. The flowers are small, white, nearly sessile, and grow three or four together at the axils of the leaves. They are often diœcious. The calyx is persistent; the segments of the corolla are obtuse; the stamens usually six in number, and furnished with oblong anthers; the germ large, green, roundish, and surmounted by a short style, terminating in an obtuse stigma. The fruit when ripe consists of glossy, scarlet, roundish berries, about the size of a pea, containing six cells and six seeds. Several of these berries are clustered together so as to form little bunches at irregular intervals on the stem. In the latter part of autumn, after the leaves have fallen, they still remain attached to the stem, and render the shrub a striking object in the midst of the general nakedness of vegetation. Hence the plant has received the name of *winter-berry*, by which it is frequently designated.

It grows in all parts of the United States, from Canada to Florida, frequenting low wet places, such as swamps, and the borders of ponds, ditches, and streams. Its flowers appear in June. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes with the bark, which is the proper officinal portion.

The dried bark is in slender pieces, more or less rolled, brittle, greenish-white internally, and covered with a smooth epidermis which is easily separable, and of a whitish-ash colour, alternating or mingled with brown. It has no smell. The taste is bitter and slightly astringent. Boiling water extracts the virtues of the bark.

Medical Properties and Uses. Black alder is usually considered tonic and astringent; and is among the remedies which have been proposed as substitutes for Peruvian bark, with which, however, it has very little analogy. It has been recommended in intermittent fever, diarrhœa, and other diseases connected with a debilitated state of the system, especially gangrene and mortification. It is a popular remedy in gangrenous or flabby and ill-conditioned ulcers, and in chronic cutaneous eruptions, in which it is given internally, at the same time that it is applied locally in the form of a wash or poultice. Any favourable influence which it may exert over these affections must be ascribed rather to a peculiar alterative property, than to its tonic and astringent powers, which are very feeble.

It may be used in substance or decoction. The dose of the powder is from thirty grains to a drachm, to be repeated several times a day. The decoction, which is usually preferred both for internal and external use, may be prepared by boiling two ounces of the bark with three pints of water to a quart, and given in the dose of two or three fluidounces. A saturated tincture, as well of the berries as of the bark, is sometimes employed.

W.

PRUNUM. *U.S.*

Prunes.

"Prunus domestica. Fructus siccatus. *The dried fruit.*" *U.S.*

Off. Syn. PRUNA. Prunus domestica. Drupæ exsiccatæ. *Lond.;* PRUNI DOMESTICÆ FRUCTUS. Fructus siccatus. *Ed.;* PRUNUS DOMESTICA. Fructus siccatus. *Dub.*

Pruneaux, *Fr.;* Pflaumen, *Germ.;* Pruni, *Ital.;* Ciruelas secas, *Span.*

Prunus. *Sex. Syst.* Icosandria Monogynia.—*Nat. Ord.* Amygdaleæ.

Gen. Ch. *Calyx* five-cleft, inferior. *Petals* five. *Nut of the drupe* with sutures somewhat prominent. *Willd.*

Prunus domestica. Willd. *Sp. Plant.* ii. 995; Woodv. *Med. Bot.* p. 520. t. 187. The cultivated prune or plum tree is so well known as to render a minute description unnecessary. We merely give the specific character. "*Peduncles* subsolitary; *leaves* lanceolate, ovate, convolute; *branches* not spiny." The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the dried fruit only that is officinal.

The prunes brought to our market come chiefly from the South of France, the best from the port of Bordeaux. They are derived from the variety of the tree named *Juliana* by Linnæus. The fresh fruit, called *prune de Saint Julien* by the French, is of an oval shape, nearly an inch in length, and of a deep violet colour. It is prepared by drying in the sun after having been exposed to the heat of an oven. The finest prunes, used on the tables in France, are prepared from the larger kinds of plums, such as the *Saint Catharine* and *Reine-Claude* or *green-gage*. An inferior sort is brought from Germany.

Prunes have a feeble odour, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. In Germany they obtain from this fruit a kind of brandy, which in some districts is much employed. Bonneberg, a German chemist, has succeeded in extracting crystallizable sugar, equal to that of the cane.

Medical Properties and Uses. Prunes are laxative and nutritious, and stewed with water form an excellent diet in cases of costiveness, especially during convalescence from febrile and inflammatory diseases. As they impart their laxative property to water in which they are boiled, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is also used in the preparation of laxative confections. Too largely taken in a debilitated state of the digestive organs, they are apt to occasion flatulence, and griping pain in the stomach and bowels.

PRUNUS LAURO-CERASUS. Folia. *Dub.*

Leaves of Cherry-Laurel.

Laurier cerise, *Fr.*; Kirschlorbeer, *Germ.*; Lauro-ceraso, *Ital.*

Prunus. See PRUNUM.

Prunus Lauro-cerasus. Willd. *Sp. Plant.* ii. 988; Woodv. *Med. Bot.* p. 513. t. 185.—*Cerasus Lauro-cerasus*, De Cand. *Prod.* ii. 540. This is a small evergreen tree, rising fifteen or twenty feet in height, with long spreading branches, which, as well as the trunk, are covered with a smooth blackish bark. The leaves, which stand alternately on short strong footstalks, are oval oblong, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit consists of oval drupes, very similar to small black cherries, both in their shape and internal structure.

The cherry-laurel is a native of Asia Minor, but has been introduced into Europe, throughout which it is cultivated, both for medical use and for the beauty of its shining evergreen foliage. Almost all parts of it are more or less impregnated with the odour supposed to indicate the presence of hydrocyanic acid. The leaves only are officinal.

In their recent and entire state they have scarcely any smell, but when bruised they emit the characteristic odour of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the peculiar flavour of the peach kernel. By drying they lose their sensible properties and become inert. They contain a peculiar volatile oil and hydrocyanic acid, both of which are separated by distillation with water, which they strongly impregnate with their flavour. The oil resembles that of bitter almonds, for which it is said to be sometimes sold in the shops in Europe, where it is employed to flavour liquors and various culinary preparations; but as it is highly poisonous, dangerous consequences may result from its careless use. It has not been determined how much of its action is dependent on the oil itself, and how much on the hydrocyanic acid which is combined with it. The fresh leaves are occasionally used to flavour milk, cream, &c.; and more safely than the oil; though they also are poisonous when too largely employed.

Medical Properties and Uses. The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid; and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it is deteriorated by age; and therefore, as kept in the shops, must be of variable strength. Hence, while Hufeland directs only twenty drops for a dose every two hours, to be gradually increased to sixty drops, M. Fouquier has administered several ounces without effect. Another source of inequality of strength must be the variable quality of the leaves, according to the time they have been kept after separation from the tree, and probably also to their age and degree of development. It is not, therefore, to be regretted, that the want of the plant in this country has prevented the introduction of the distilled water into our shops.

Off. Prep. Aqua Lauro Cerasi, *Dub.* W.

PRUNUS VIRGINIANA. *U.S.*

Wild-cherry Bark.

"Prunus Virginiana. Cortex. *The bark.*" *U.S.*

Prunus. See PRUNUM.

Prunus Virginiana. Willd. *Sp. Plant.* ii. 985.—*Cerasus Virginiana.* Michaux, *N. Am. Sylv.* ii. 205. The wild-cherry tree is, according to Michaux, one of the largest productions of the American forest. Individuals were seen by that botanist on the banks of the Ohio from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But as usually met with in the Atlantic States, the tree is of much smaller dimensions. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semi-circularly in thick narrow plates, and by this peculiar character serves as a distinguishing mark of the tree when the foliage is too high for inspection. The leaves are oval oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green, and supported alternately upon petioles, which are furnished with from two to four reddish glands. The flowers are small, white, and collected in long erect racemes. They appear in May, and are followed by globular drupes about the size of a pea, and when ripe of a shining blackish-purple colour.

This species of Prunus grows throughout the Union, flourishing most in those parts where the soil is fertile and the climate temperate, and abounding in the Middle Atlantic States, and in those which border on the Ohio. In the neighbourhood of Philadelphia, it affects open situations, growing solitary in the fields and along the fences, and seldom aggregated in woods or groves. It is highly valued by the cabinetmakers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint, which deepens with age. The fruit has a sweetish, astringent, bitter taste; and is much employed in some parts of the country to impart flavour to spirituous liquors. The inner bark is the part employed in medicine, and is obtained indiscriminately from all parts of the tree, though that of the roots is most active. It should be preferred recently dried, as it deteriorates by keeping.

Properties. Wild-cherry bark as kept in the shops is in pieces of various sizes, more or less curved laterally, usually destitute of epidermis, of a lively cinnamon colour, brittle, and pulverizable, presenting a reddish-gray fracure, and affording a fawn-coloured powder. In the fresh state, or when boiled in water, it emits an odour resembling that of peach leaves. Its taste s agreeably bitter and aromatic, with the peculiar flavour of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Madeira wine in appearance. Its peculiar flavour is injured by boiling, in consequence of the volatilization of the principle upon which it depends. From a recent analysis by Mr. Proctor, of Philadelphia, it appears to contain volatile oil, hydrocyanic cid, starch, resin, tannin, gallic acid, fatty matter, lignin, red colouring mater, salts of lime and potassa, and iron. The volatile oil may be obtained y distilling the same portion of water successively from several different porons of the bark. It is of a light straw colour, and very analogous in its properties to the volatile oil of bitter almonds. In the quantity of two drops it proved fatal to a cat in less than five minutes. (*Journ. of the Phil. Col. of Pharm.* vi. 8.)

Medical Properties and Uses. This bark is among the most valuable of our indigenous remedies. Uniting with a tonic power, the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which a debilitated condition of the stomach, or of the system at large, is united with general or local irritation. When largely taken it is said to diminish the action of the heart, an effect which is ascribable to the hydrocyanic acid contained in it. Dr. Eberle states that copious draughts of the cold infusion, taken several times a-day, and continued for nearly two weeks, had the effect of reducing his pulse from seventy-five to fifty strokes in the minute. The remedy is highly useful in the hectic fever of scrofula and consumption, in the treatment of which it has long been a favourite with many American practitioners. In the general debility which often succeeds inflammatory diseases, it has also been found advantageous, and i tis well adapted to many cases of dyspepsia. It has been used successfully in intermittent fever, but in this complaint is much inferior to cinchona.

It may be used in powder or infusion. The dose of the powder is from thirty grains to a drachm. The infusion is properly directed by our national Pharmacopœia to be prepared with cold water. (See *Infusum Pruni Virginianæ.*)

PYRETHRUM. *Dub.*

Pellitory Root.

"Anthemis Pyrethrum. *Radix.*" *Dub.*

Off. Syn. PYRETHRI RADIX. Anthemis Pyrethrum. Radix. *Lond.*; ANTHEMIDIS PYRETHRI RADIX. *Ed.*

Pyrèthre, *Fr.;* Bertram Wurtzel, *Germ.;* Piretro, *Ital.;* Pelitre, *Span.*

Anthemis. See ANTHEMIS.

Anthemis Pyrethrum. Willd. *Sp. Plant.* iii. 2184; Woodv. *Med. Bot.* p. 50. t. 20. The root of this plant is perennial, and sends up numerous stems, which are usually trailing at the base, erect in their upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow nearly linear segments of a pale green colour. The florets of the disk are yellow; the rays are white on their upper surface, and reddish or purple beneath and at their edges.

The plant is a native of the Levant, Barbary, and the Mediterranean coast of Europe. The root is the only part used under the name of pellitory. According to Hayne, the pellitory of the shops is derived from the *Anacyclus officinarum*, a plant cultivated in Thuryngia for medical purposes. This remark, however, can apply only to Germany.

Properties. The dried root of the *A. Pyrethrum* is about the size of the little finger, cylindrical, straight or but slightly curved, wrinkled longitudinally, of an ash-brown colour externally, whitish within, hard and brittle, sometimes furnished with a few radicles. It is destitute of odour, though when fresh, of a disagreeable smell. Its taste is peculiar, slight at first, but afterwards acidulous, saline, and acrid, attended with a burning and tingling sensation over the whole mouth and throat, which continues for some time, and excites a copious flow of saliva. Its constituents, according to M. Gauthier, are a fixed oil, a yellow colouring matter, gum, inulin, lignin, with traces of volatile oil and of muriate of lime. The pungency depends on the fixed oil, which, however, is considered by M. Boullay to be more closely allied to the resins than to the principles among which it is placed.

Medical Properties and Uses. Pellitory root is a powerful irritant, used almost exclusively as a sialagogue in certain forms of headach, rheumatic and neuralgic affections of the face, toothach, &c., or as a local stimulant in palsy of the tongue or throat, and in relaxation of the uvula. For these purposes it may be chewed, or employed as a gargle in decoction or vinous tincture. It is seldom prescribed by medical practitioners in this country. W.

QUASSIA. *U.S.*

Quassia.

"Quassia excelsa. *Willd.;* Simaruba excelsa. *De Candolle.* Lignum. *The Wood.*" *U.S.*

Off. Syn. QUASSIÆ LIGNUM. Quassia excelsa. Lignum. *Lond.;* QUASSIÆ EXCELSÆ LIGNUM. *Ed.;* QUASSIA EXCELSA. Lignum. *Dub.*

Bois de quassie, *Fr.;* Quassienholz, *Germ.;* Legno della quassia, *Ital.;* Leno de quassia, *Span.*

Quassia. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Magnoleæ, *Juss.;* Simarubaceæ, *Richard, Lindley.*

Gen. Ch. Calyx five-leaved. *Petals* five. *Nectary* five-leaved. *Drupes* five, distant, bivalve, one-seeded, inserted into a fleshy receptacle. *Willd.*

Of the species included by Linnæus in this genus, some, as the *Quassia amara*, are hermaphrodite; others, as the *Q. excelsa* and *Q. Simaruba*, are polygamous. The latter have been associated together by De Candolle in a distinct genus, with the title *Simaruba;* and the *Simaruba excelsa* of this author has been recognised, in the United States Pharmacopœia, as a synonyme of the officinal quassia plant.

The medicine was formerly thought to be obtained from the *Quassia amara;* but more than twenty years since, Lamarck stated that in consequence of the scarcity of this tree, the *Quassia excelsa* had been resorted to as a substitute, and the Pharmacopœias at present agree in acknowledging the latter as the officinal plant. It is, however, the opinion of Martius, that the genuine quassia of Surinam is the *Q. amara*; and we shall, therefore, give a brief description of both species.

Quassia excelsa. Willd. *Sp. Plant.* ii. 569.—*Simaruba excelsa*, De Cand. *Ann. du Mus.* xvii. 424; Hayne, *Dartsel. und Beschreib., &c.* ix. 16. As its name imports, this is a lofty tree, attaining sometimes not less than one hundred feet in height, with a straight smooth tapering trunk, which is often three feet in diameter near its base, and covered with a smooth gray bark. The leaves are pinnate, with a naked petiole, and oblong pointed leaflets standing upon short footstalks, in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green colour, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. This species inhabits Jamaica and the Caribbean islands, where it is called *bitter ash.* The wood is the officinal portion.

Quassia amara. Willd. *Sp. Plant.* ii. 567; Woodv. *Med, Bot.* p. 574. t. 04. The bitter quassia is a small branching tree or shrub, with alternate eaves, consisting of two pairs of opposite pinnæ, with an odd one at the end.

The leaflets are elliptical, pointed, sessile, smooth, of a deep green colour on their upper surface, and paler on the under. The common footstalk is articulated, and edged on each side with a leafy membrane. The flowers, which are hermaphrodite and decandrous, have a bright red colour, and terminate the branches in long racemes. The fruit is a two-celled capsule, containing globular seeds. The *Q. amara* is a native of Surinam, and is said also to grow in some of the West India islands. Its root, bark, and wood were formerly officinal. They are all excessively bitter, as are also the leaves, flowers, and fruit, and in fact the whole plant. It is uncertain whether any of the produce of this tree reaches our markets.

Quassia comes in cylindrical billets of various sizes, from an inch to near a foot in diameter, and several feet in length. These are frequently invested with a whitish smooth bark, brittle and but slightly adherent, and possessing in at least an equal degree the virtues of the wood. Their shape and structure clearly evince that they are derived from the branches or trunk, and not, as some suppose, from the root of the tree. In the shops they are usually kept split into small pieces, or rasped.

Properties. The wood is at first whitish, but becomes yellow by exposure. It is inodorous, and has a purely bitter taste, which is surpassed by that of few other substances in intensity and permanence. It imparts all its active properties, with its bitterness and yellow colour, to water and alcohol. The extract obtained by gently evaporating the aqueous infusion, is ranked by Dr. Thomson among the proximate vegetable principles under the name of *quassin.* It is a brownish-yellow substance, to a certain degree transparent, soluble in water and alcohol, and remarkable for the very narrow circle of its chemical affinities. Of all the reagents in common use as medicines, nitrate of silver and acetate of lead alone produce precipitates with its solution. These, therefore, are the only salts incompatible with the infusion of quassia.

Medical Properties and Uses. Quassia has in the highest degree all the properties of the simple bitters. It is purely tonic, invigorating the digestive organs, with little excitement of the circulation, or increase of animal heat. It has not been very long known as a medicine. About the middle of the last century, a negro of Surinam, named Quassi, acquired considerable reputation in the treatment of the malignant fevers of that country, by a secret remedy, which he was induced to disclose to Mr. Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756; and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. Quassia is useful in all cases in which a simple tonic impression is desirable. It is particularly adapted to dyspepsia from debility of stomach, and to that weakened state of the digestive organs which sometimes succeeds acute disease. It may also be given with advantage in the remission of certain fevers in which tonics are demanded. No one at present would expect from it any peculiar controlling influence over malignant fevers. It is said to be largely consumed in England by the brewers, who employ it to impart bitterness to their liquors.

It is most conveniently administered in infusion. (See *Infusum Quassiæ.*) The watery extract, made by evaporating the decoction is a very convenient preparation, and may be given in the form of pill, in the dose of five grains. The difficulty of reducing the wood to powder, is an objection to its use in substance. It may, however, be employed in a dose varying from a scruple to a drachm, repeated three or four times a day.

Gen. Ch. Male. *Calyx* commonly five-cleft. *Corolla* none. *Stamens* five to ten. Female. *Calyx* one-leafed, entire, rough. *Corolla* none. *Styles* two to five. *Nut* coriaceous, surrounded at the base by the persistent calyx. *Willd.*

This extensive genus comprises not less than eighty species, of which between thirty and forty are found within the limits of the United States. Many of these are applied to important practical purposes. In the northern hemisphere the oak is the most valuable, as it is the most widely diffused of all forest trees. Notwithstanding the great number of species, few, comparatively, have found a place in the officinal catalogues. The *Q. robur* or common European oak, and the *Q. pedunculata* or European white oak, are the only species admitted by the British Colleges. As these do not grow in the United States, and their products are not imported, it is unnecessary to treat of them particularly in this work. According to Michaux, they grow in the same countries, frequently together, constituting the greater part of the forests of Europe, and spreading over almost the whole northern section of Asia, and the northern coast of Africa. The *Q. pedunculata* is the common British oak, celebrated as well for its majestic growth and the venerable age which it attains, as for the strength and durability of its timber, and the high purposes to which it has been applied. Our own Pharmacopœia recognises only the *Q. alba* or white oak, and the *Q. tinctoria* or black oak; but several other species afford barks which are equally useful, and perhaps as much employed. Such are the *Q. falcata* or Spanish oak, the *Q. prinus* or white chesnut oak, and the *Q. montana* or rock chesnut oak. The remarks which follow in relation to the white oak bark, will apply also to that of the three last mentioned species. The bark of the *Q. tinctoria* is somewhat peculiar.

1. *Quercus alba.* Willd. *Sp. Plant.* iv. 448; Michaux, *N. Am. Sylv.* i. 17. Of all the American species, the *white oak* approaches nearest in the character of its foliage, and the properties of its wood and bark, to the *Q. pedunculata* of Great Britain. When allowed to expand itself freely in the open field, it divides at a short distance from the ground into numerous widely spreading branches, and attains under favourable circumstances a magnificent size. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of the other species. The

leaves are regularly and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter, and till the circulation of the sap returns in spring. The acorns are large, ovate, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly an inch in length.

The white oak abounds in the Middle States, and extends also through the whole Union, though comparatively rare in the northern, southern, and western sections. It is the most highly valued for its timber of all the American oaks, with the exception of the *live oak* (*Q. virens*), which is preferred in ship-building. The bark is sometimes used for tanning, but that of the *red* and *Spanish oaks* is preferred for this purpose. All parts of the tree, with the exception of the epidermis, are more or less astringent; but this property predominates in the fruit and the bark, the latter of which is the only officinal portion.

Oak bark, deprived of its epidermis, is of a light brown colour, of a coarse fibrous texture, and not easily pulverized. It has a feeble odour, and a rough, astringent, and bitterish taste. Water and alcohol extract its active properties. The chief soluble ingredients are tannin, gallic acid, and extractive matter. It is upon the tannin that its medical virtues as well as its use in the preparation of leather chiefly depend. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark; and the English oak is said to yield four times as much in spring as in the winter. Sir H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle as of extractive. Vauquelin states that the infusion of oak bark does not, like that of galls, precipitate tartar emetic.

2. *Quercus tinctoria*. Willd. *Sp. Plant.* iv. 444; Michaux, *N. Am. Sylv.* i. 91. The *black oak* is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark brown colour. The leaves are ovate oblong, pubescent, slightly sinuated, with oblong, obtuse, mucronate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a colouring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow colour, which is deepened by alkalies, and rendered brighter by acids. Under the name of *quercitron*, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow colour. It contains also much tannin; but is less used in tanning than the other barks, in consequence of the colour which it imparts to the leather.

Medical Properties and Uses. Oak bark is astringent and somewhat tonic. It has been given with advantage in intermittent fever, obstinate chronic diarrhœa, and certain forms of passive hemorrhage; but it is not much employed as an internal remedy. Externally applied it is often productive of benefit. The decoction may be advantageously used as a bath, particularly for children, when a combined tonic and astringent effect is desirable, and the stomach is not disposed to receive medicines kindly. It has been employed in this way in marasmus, scrofula, intermittent fevers, chronic diarrhœa, and cholera infantum. As an injection in leucorrhœa, a wash in prolapsus ani and hemorrhoidal affections, and as a gargle in slight inflammation of the fauces, attended with prolapsed uvula, the decoction is often highly useful. Reduced to powder and made into a poultice, the bark was recommended by the late Dr. Barton as an excellent application in cases of external gangrene and mortification; and the infusion obtained from tanners' vats has been used beneficially as a wash in flabby, ill-conditioned ulcers.

The bark may be given internally in the form of powder, extract, or decoction. The dose of the powder is from thirty grains to a drachm, of the extract about half as much, of the decoction two fluidounces. (See *Decoctum Quercûs.*)

Black-oak bark is considered inferior to the white-oak as an internal remedy, in consequence of being more disposed to irritate the bowels.

The fruit of the oak is sometimes used as an astringent; and a decoction made from roasted acorns has been highly recommended by Hufeland as a remedy in scrofula.

RANUNCULUS. *U.S. Secondary.*

Crowfoot.

"Ranunculus bulbosus. Planta. *The plant.*" *U.S.*

Off. Syn. RANUNCULUS ACRIS. Folia. RANUNCULUS FLAMMULA. Herba recens. *Dub.*

Ranunculus. *Sex. Syst.* Polyandria Polygynia.—*Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx five-leaved. *Petals* five, having the inner side of each claw furnished with a melliferous pore. *Seeds* naked, numerous. *Nuttall.*

Most of the plants belonging to this genus have the same acrid properties. Several of them grow together in our fields and pastures, and from their close resemblance in appearance, are confounded under the common name of *buttercup*, applied to them from the colour and shape of their flowers. Those which are most abundant are believed to have been introduced from Europe. Such are the *R. bulbosus*, *R. acris*, and *R. repens*, which, with the *R. sceleratus*, may be indiscriminately used. In Europe, the *R. sceleratus* appears to have attracted most attention; in this country, the *R. bulbosus*. The latter is the only one designated by our Pharmacopœia. The *R. acris* and *R. flammula* are directed by the Dublin College.

Ranunculus bulbosus. Willd. *Sp. Plant.* ii. 1324; Bigelow, *Am. Med. Bot.* iii. 61. This species of crowfoot is perennial, with a bulbous, solid, fleshy root, which sends up annually several erect, round, and branching stems, from nine to eighteen inches high. The radical leaves, which stand on long footstalks, are ternate or quinate, with lobed and dentate leaflets. The leaves of the stem are sessile and ternate, the upper more simple. Each stem supports several solitary, bright yellow, glossy flowers, upon furrowed, angular peduncles. The leaves of the calyx are reflexed or bent downwards against the flowerstalk. The petals are obcordate and arranged so as to represent a small cup in shape. At the inside of the claw of each petal is a small cavity, which is covered with a minute wedge-shaped emarginate scale. The fruit consists of numerous naked seeds, collected in a spherical head. The stem, leaves, peduncles, and calyx are hairy.

In the months of May and June our pastures are everywhere adorned with the rich yellow flowers of this species of Ranunculus. Somewhat later the *R. acris* and *R. repens* begin to bloom, and a succession of similar flowers is maintained till September. The two latter species prefer a moister ground, and are found most abundantly in meadows. The *R. sceleratus* is found in ponds and ditches. In all these species, the whole plant is pervaded by a volatile acrid principle, which is dissipated by drying or by the application of heat. This principle may be separated by distillation. Dr. Bigelow found that water distilled from the fresh plant has an acrid taste, and produces when swallowed a burning sensation in the stomach; and that it retains these properties for a long time if kept in closely stopped bottles. The plant itself when chewed excites violent irritation in the mouth and throat; inflaming and even excoriating the tongue and inside of the cheeks and lips, if not quickly discharged. Both the root and herbaceous portion of the *R. bulbosus* are officinal.

Medical Properties and Uses. Crowfoot, when swallowed in the fresh state, produces heat and pain in the stomach, and if the quantity be considerable, may excite fatal inflammation. It is, however, never used internally. The property for which it has attracted the attention of physicians is that of inflaming and vesicating the skin; and before the introduction of the Spanish fly into use, it was much employed for this purpose. But the uncertainty and occasional violence of its action have nearly banished it from regular practice. While on some individuals it appears to produce scarcely any effect, on others it acts very speedily, exciting extensive and troublesome inflammation, which sometimes terminates in deep and obstinate ulcers. It probably varies in strength with the season, and in the dried state, or boiled with water it is wholly inert. The decoction, moreover, is inert, in consequence of the escape of the acrid principle. Nevertheless, the plant has been very properly retained by the Pharmacopœia in the catalogue of medicines of secondary importance; as occasions may occur when the practitioner in the country may find advantage in having recourse to its powerful rubefacient and epispastic operation. RESINA. *U.S.*

Resin.

"Pinus palustris, et aliæ. Residuum postquam oleum terebinthinæ destillatum est. *The residuum after the distillation of the oil of turpentine.*" *U.S.*

Off. Syn. RESINA FLAVA. Pinus sylvestris. *Lond.*; PINI RESINA SOLIDA, oleo volatile privata, *vulgo*, RESINA ALBA. *Ed.*; PINUS SYLVESTRIS. Resina. *Dub.*

Resine blanche, Resine jaune, *Fr.;* Fichtenharz, *Germ.;* Ragea di pino, *Ital.;* Resina de pino, *Span.*

After the distillation of the volatile oil from the turpentines, (see *Terebinthina,*) a resinous matter remains, which on the continent of Europe is called *colophony*, but in our language is commonly known by the name of *rosin.* It is the Resina of the United States Pharmacopœia, and the Resina flava or *yellow resin*, of the London and Dublin Colleges. When this, in a state of fusion, is strongly agitated with water, it acquires a distinct appearance, and is now denominated Resina alba or *white resin.* Before describing these officinal substances, it may be proper to enumerate the characteristic properties of the proximate principles which chemists designate by the term resins.

Pure resins are solid, brittle, inodorous, insipid, generally of a yellowish colour and semitransparent, with a smooth and shining fracture. Their sp. gr. varies from 0.92 to 1.2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are dissolved by alcohol, ether, and the essential oils; and their alcoholic and ethereal solutions afford precipitates upon the addition of water. With pure potassa and soda they unite to form soaps which are soluble in water; and the same result takes place when they are heated with the solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mutual decomposition; and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.

Common or *yellow resin*, in its purest state, is beautifully clear and pellucid, but much less so as it is commonly found in the shops. Its odour and taste are usually in a slight degree terebinthinate; its colour yellowish-brown with a tinge of olive, and more or less dark according to its purity. It is rather heavier than water. At 276° F. it fuses, is completely liquid at 306°, begins to emit bubbles of gas at 316°, and is entirely decomposed at a red heat. Its constituents are carbon, oxygen, and hydrogen; but the exact proportions are differently stated by different chemists.

White resin differs from the preceding only in being opaque and of a whitish colour. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent.

Medical Uses. Resin is important as an ingredient of ointments and plasters; but is never used internally.

RHAMNI BACCÆ. *Lond.*

Buckthorn Berries.

"Rhamnus catharticus. *Baccæ.*" *Lond.*

Off. Syn. RHAMNI CATHARTICI SUCCUS. Ex baccis. *Ed.;* RHAMNUS CATHARTICUS. Baccæ. *Dub.*

Baies du nerprun, *Fr.;* Kreutzbeeren, *Germ.;* Bacche del spino cervino, *Ital.;* Bayas e ramno catartico, *Span.*

Rhamnus. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Rhamneæ.

Gen. Ch. Calyx tubular. *Corolla* scales defending the stamens, inserted nto the calyx. *Berry. Willd.*

Rhamnus catharticus. Willd. *Sp. Plant.* i. 1092; Woodv. *Med. Bot.* p. 594. t. 210. The purging buckthorn is a shrub seven or eight feet high, with branches terminating in a sharp spine. The leaves are in fascicles, on hort footstalks, ovate, serrate, veined. The flowers are usually diœcious, in clusters, small, greenish, peduncled, with a four-cleft calyx, and four very small scale-like petals, placed, in the male flower, behind the stamens, which equal them in number. The fruit is a four-seeded berry.

The shrub is a native of Europe, and is said to have been found growing wild in this country. It was first discovered in the Highlands of New York by Dr. Barratt. (*Eaton's Manual.*) It flowers in May and June, and ripens its fruit in the latter part of September. The berries are the officinal portion. When ripe they are about the size of a pea, round, somewhat flattened on the summit, black, smooth, shining, with four seeds surrounded by a green, juicy parenchyma. Their odour is unpleasant, their taste bitterish, acrid, and nauseous. The expressed juice has the colour, odour, and taste of the parenchyma. It is reddened by the acids, and from deep green is rendered light green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness with the addition of lime or an alkali, it forms the colour called by painters *sap-green*. The dried berries of another species, *R. infectorius*, yield a rich yellow colour, for which they are much employed in the arts under the name of *French berries.*

Medical Properties and Uses. Both the berries and the expressed juice are actively purgative; but, as they are apt to occasion nausea, and severe griping pain in the bowels, with much thirst and dryness of the mouth and throat, they are now little employed. They formerly enjoyed considerable reputation as a hydragogue cathartic in dropsy; and were given also in rheumatism and gout. The only shape in which they are used in this country is that of the syrup, which is sometimes, though rarely, added to hydragogue or diuretic mixtures. (See *Syrupus Rhamni.*)

The dose of the recent berries is about a scruple, of the dried berries a drachm, and of the expressed juice a fluidounce.

Gen. Ch. Calyx none. *Corolla* six-cleft, persistent. *Seed* one, three-sided. *Willd.*

Notwithstanding the length of time that rhubarb has been in use, and the attention which it has received from naturalists, the question yet remains unsettled from what precise plant it is derived. The remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade in this drug is guarded, have prevented any accurate information on the subject. All that we certainly know, is that it is the root of one or more species of Rheum. It is true that the Pharmacopœias undertake to designate the particular species. Thus, the London College recognises the *R. palmatum*, the Dublin both this and the *R. undulatum*, and in the United

States Pharmacopœia the drug is referred to the *R. palmatum* and other species not particularized. But the evidence in favour of either of these species is by no means unequivocal, as will appear from the following brief history.

The *rhabarbarum* of the ancients, from which the modern name *rhubarb* was derived, is supposed to have been the root of the *Rheum Rhaponticum*, which grows on the banks of the Caspian sea and the Wolga; and this species was formerly believed to be the source of the medicine now in use. But the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not till the year 1732 that any probable information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France and Rand in England, which were said to be of the species which afforded the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum Rhabarbarum*, a title which has since given way to *Rheum undulatum*. At a subsequent period, Kauw Boerhaave obtained from a merchant who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant which produced the root he sold. These seeds having been planted, yielded two species of Rheum, the *R. undulatum*, and another which Linnæus pronounced to be distinct, and named *R. palmatum*. Seeds transmitted by Dr. Mounsey from St. Petersburg to Dr. Hope, and planted in the botanic garden at Edinburgh, produced the latter species; and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described A. D. 1767 by the younger Linnæus, two years after the appearance of Dr. Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favour of the *R. palmatum* and *R. undulatum*. The claims of another species were afterwards presented. Pallas, upon exhibiting the leaves of the *R. palmatum* to some Bucharian merchants, of whom he was making inquiries relative to the rhubarb plant, was told that the leaves of the latter were entirely different in shape; and the description he received of them corresponded more closely with those of the *R. compactum*, than of any other known species. Seeds of this plant were moreover sent to Miller from St. Petersburg, as those of the true Tartarian rhubarb. Within a few years the attention of naturalists has been called to a fourth species, for which the same honour is claimed. Dr. Wallich, superintendent of the botanical garden at Calcutta, received seeds which were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya mountains and the highlands of Tartary. These produced a species not hitherto described, which Dr. Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Mr. Don and of Colebrooke. From what has been said, it is obvious that no species yet mentioned can be considered as the undoubted source of commercial rhubarb, the plant having, in no instance, been seen and examined by naturalists in its native place. Sievers, an apothecary sent to Siberia in the reign of Catharine II. with the view of improving the cultivation of the native rhubarb, asserts, from information given him by the Bucharians, that all the seeds procured under the name of true rhubarb are false, and pronounces "all the descriptions in all the Materia Medicas to be incorrect." This assertion, however, has no relation to the *R. australe* which has been subsequently described; but of this plant it is said that the roots dried by the medical officers of the British army in India differ from true rhubarb in appearance and power. Stlll, however, it is possible that the medicine is derived from one or more, or even from all the species alluded to, and if it should be objected that their roots, as cultivated in Europe, have not the precise qualities or composition of the Asiatic rhubarb, the answer is obvious, that the product of the same plant is often known to vary exceedingly with diversities of soil, climate, and culture.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerons very large petiolate leaves, and terminating in lengthened branching panicles composed of small and very numerous flowers, resembling those of the Rumex or dock. Without describing the several species minutely, we shall mention those particulars with regard to them by which they are respectively characterized.

Rheum palmatum. Willd. *Sp. Plant.* ii. 489; Woodv. *Med. Bot.* p. 662. t. 231. The root of this species is large, divided into thick branches, brittle, externally brown, internally of a deep yellow colour. The leaves are palmate, with five or seven deeply sinuated pointed segments, are somewhat rough, and stand on long smooth footstalks, which are somewhat channeled on their upper surface, and rounded on the sides. It is said to inhabit China, in the vicinity of the great wall.

R. undulatum. Willd. *Sp. Plant.* ii. 489; Loudon's *Encyc. of Plants,* p. 335. The root of the *R. undulatum* is large, roundish, externally brown, internally yellow, and divided into numerous ramifications which penetrate deeply into the soil. The leaves are long, pointed, wavy, and somewhat villous, have at their base on each side a deep sinus, and are supported upon footstalks flat on their upper surface, with acute edges. This species is a native of Siberia, and probably also of Tartary.

R. compactum. Willd. *Sp. Plant.* ii. 489; Loudon's *Encyc. of Plants.* p. 336. This is distinguished by the leaves being very smooth, shining, somewhat lobed, very obtuse, and finely denticulate. The root is thick, divided into many long branches, and internally of a fine reddish-yellow colour. The plant is said to be a native of Tartary and China.

R. australe. Don, *Prod. Flor. Nepal.* p. 75; Sprengel, *Syst. Veg.* iv. 156. "The leaves of this species are roundish cordate, obtuse, rough beneath and on the margin, with the sinus at the base dilated, and with furrowed roundish footstalks. The branches and peduncles are papillose-scabrous; the leaflets of the perianth oval oblong, finely crenate at the apex." The plant grows in the highlands of Chinese Tartary and in the Himalaya mountains.

R. Rhaponticum. Willd, *Sp. Plant.* ii. 488; Loudon's *Encyc. of Plants,* p. 335. The leaves are very large, cordate, obtuse, smooth, with the veins on the under surface hairy, the sinus at the base dilated, and the footstalks furrowed above and rounded at the edge. The root is large, fleshy, often branching, of a yellow colour diversified with red internally, and reddish-brown on the outside. The Rhapontic rhubarb grows on the banks of the Caspian sea, in the deserts between the Wolga and the Oural, and on the mountains of Krasnojar in Siberia.

The leafstalks of the different species of Rheum have a pleasant acid taste, and are used for making tarts and pies, which are not unlike those made with gooseberries. It is for this purpose only that the plants are cultivated in the United States. The *R. Rhaponticum* is the common pie-rhubarb. The *R. palmatum* and *R. undulatum* are sometimes found in our gardens.

In relation to the culture and preparation of rhubarb, our information is almost as uncertain as on the subject of its natural history. The accounts received from the Bucharian merchants are very discordant, and few intelligent travellers have penetrated into the country where the medicine is collected. We shall present, however, a brief abstract of what we have been able to collect upon the subject from the authorities we have consulted.

Rhubarb is produced abundantly in the elevated lands of Tartary about the lake Koko Norr, and is said to be cultivated in the neighbouring Chinese province of Shen-see. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb are exclusively derived; but the root is also collected in Boutan and Thibet, on the north of the Himalaya mountains; and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. We are told by Mr. Bell, who, on a journey from St. Petersburg to Pekin, had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously in tufts at uncertain distances, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection till it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground it is cleaned, deprived of its cortical portion and of the smaller branches, and then divided into pieces of a convenient size. These are bored with holes, and strung upon cords to dry, according to Mr. Bell, about the tents and on the horns of the sheep, according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Boutan, the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root; and Sievers states, that a year sometimes elapses from the period of its collection before it is ready for exportation. A very large proportion of its weight is lost in drying, according to some accounts four-fifths, to others not less than seven-eighths. It is probably in order to favour the drying that the bark is removed. The trade in rhubarb centres in the Chinese town of Si-nin, where a Bucharian company or family is established, which possesses a monopoly of this trade, in consideration of a certain tribute paid to the government. To this city the rhubarb is brought from the various places of its collection, and having been duly assorted and undergone further preparation, is transmitted partly to Russia, partly to the coast of China; so that the drug which reaches us through St. Petersburg, is procured from the same neighbourhood with that imported from Canton. But it will soon be seen that there are differences between the Russian and Chinese rhubarb, which would seem to indicate a different origin, and might authorize doubts as to the entire accuracy of the above accounts. Besides the two commercial varieties just mentioned, a third occasionally comes to us from Europe, where the cultivation of rhubarb has been carried on for some time with success, especially in France, Belgium, and Great Britain. Of these three varieties we shall treat under different heads, and shall add a brief account of the Rhapontic, which is entirely distinct from the others.

1. *Chinese Rhubarb.*

RHEUM SINENSE *vel* INDICUM. *Ed.*

Much the largest proportion of rhubarb consumed in this country is brought from Canton. Though somewhat inferior to the Russian, its comparative cheapness gives it a decided preference in our markets; and when of good quality it does not disappoint the expectations of physicians.

It is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty yellow colour externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. It is heavier than the Russian rhubarb, has a texture rather close and compact, and when broken presents a ragged uneven surface, variegated with intermingled shades of red, yellow, and white, which are sometimes diversified or interrupted by darker colours. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process; and portions of the suspending cord are not unfrequently found remaining in the holes.* Chinese rhubarb has a peculiar somewhat aromatic smell, and a bitter astringent taste, feels gritty when chewed, imparts a yellow colour to the saliva, and affords a yellowish powder with a tinge of orange. With the pieces of good quality others often come mingled, which are defective from decay or improper preparation. These are usually lighter, and of a dark or russet colour. Like all the other varieties of rhubarb, this is liable to be attacked by worms; and in almost every large parcel, pieces may be found which have suffered from this cause. The want of proper care in its selection by the Chinese merchants, and the exposure incident to a long sea-voyage, are causes which contribute to its inferiority to the following variety.

2. *Russian Rhubarb.*

RHEUM RUSSICUM *vel* TURCICUM. *Ed.*

The rhubarb taken to Russia from Tartary, undergoes a peculiar preparation in conformity with the stipulations of a contract with the Bucharian merchants who furnish the supply. The best is selected, and each piece perforated in order to ascertain whether it is sound in the centre. From Si-nin it is conveyed by the Bucharian merchants to the frontier town of Kiachta, where it undergoes a rigid inspection by an apothecary stationed at that place by the Russian government. All those pieces which do not pass examination are committed to the flames; and the remainder is sent to St. Petersburg. This variety is sometimes called Turkey rhubarb, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Natolia. The circumstance of the identity of the Russian and Turkey rhubarb, and their decided difference from the Chinese, would appear to indicate a distinct origin for the two varieties.

The pieces of Russian rhubarb are irregular, and somewhat angular, appearing as if the bark had been shaved off longitudinally by successive strokes of a knife, and a portion of the interior substance removed with each shaving. They have a cleaner and fresher appearance than the Chinese, and their colour both internally and externally, though of the same general character, is somewhat more lively. They are less compact and heavy; and are cut with less facility, owing to their giving way before the knife. Another distinction is in the character of the perforations, which in the Russian rhubarb are large, frequently reaching only to the centre, and evidently made for the purpose of inspection, while in the Chinese they are small, penetrate completely through the pieces, and were intended for the passage of a suspending cord. The taste and smell of the former closely resemble those of the latter, except that the Russian is rather more aromatic. There is the same crackling under the teeth, and the same yellow stain imparted to the saliva; but the colour of the powder in this variety is a bright yellow, without the orange tinge exhibited by the Chinese.

---

* Thomson and Duncan state in their respective Dispensatories, that the pieces of Chinese rhubarb are seldom perforated. We have examined many specimens, and find, as regards the drug imported into this country, that their statement is incorrect.

The care which renders the Russian rhubarb so free from defects, tends greatly to enhance its price, and consequently to limit its consumption. Its great comparative value in the market has led to frequent attempts at adulterations; and the pieces of Chinese rhubarb are said to be sometimes cut down and prepared, so as to resemble the Russian. The fraud, however, may be detected by adverting to the peculiarities in texture, colour, and weight, by which the varieties are distinguished. Sometimes the worm-eaten pieces are made to resemble the sound, by filling up the holes with a mixture of pulverized rhubarb and mucilage, and covering over the surface with the powder. By removing this the fraud is at once revealed.

3. *European Rhubarb.*

Rheum Britannicum. *Ed.*

In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plant has been cultivated for many years; and considerable quantities of the root are annually brought into the market. The *R. palmatum* was first introduced, is most largely cultivated, and is said by M. Guibourt to afford a root, which, when of sufficient age, approaches most nearly, in sensible and chemical qualities, to the rhubarb from China. The *R. undulatum*, and *R. compactum*, are also cultivated. The following account of an establishment for the culture of these plants may prove interesting to those who may be disposed to attempt its introduction into the United States. This establishment is in the department of the Morbihan in France, and is conducted by M. Genthon, a pharmaceutist of Lorient. The quantity of rhubarb which it annually furnishes is fifteen hundred pounds. The mode of proceeding is essentially the same with that formerly pointed out by Baumé. The seeds of the several officinal species are sown in the spring in a light soil. The young shoots are transplanted in the following spring, and placed regularly at the distance of three feet from each other. The roots are not dug up till the autumn of the fifth or sixth year, when they weigh from fifteen to twenty-five pounds. In the fresh state they are more spongy than fibrous, and very difficult to dry, in consequence of the great quantity of mucilaginous and extractive matter they contain. They are first washed in water, and having been deprived of their small branches and radical fibres, are again steeped in fresh water, and cut into pieces of convenient size. The brown bark is then scraped off, and the pieces, having been soaked for three or four hours in cold water, are placed upon bundles of rods to drain, when a gummy, gelatinous matter exudes. The drying is effected in drying rooms heated to 120° or 140° of the centigrade thermometer. The rhubarb by this process loses from seventy to seventy-two per cent. of its weight, and becomes wrinkled on the surface. It is deprived of the wrinkles by grating, and is then introduced into a barrel which is made to revolve upon its axis for half an hour. The pieces are thus covered with a yellow powder arising from their friction against each other; and are made to present an appearance similar to that of the Chinese rhubarb.

Whether from the difference in species, or from the influence of soil and climate, none of the European rhubarb is equal in purgative power to that brought from Russia and China. It is usually in pieces longer than they are thick, sometimes flat, sometimes irregularly cylindrical, and in the latter case often little more than an inch in diameter. Its texture is more ligneous than that of the Asiatic varieties, its colours more compactly arranged, and its powder more strongly tinged with red. It has a nauseous odour and astringent taste, scarcely feels gritty when chewed, and but slightly colours the saliva. Duncan says that the British rhubarb is commonly pasty under the pestle. This quality is probably attributable to imperfect drying. The roots of the different species are not distinguished in commerce.

4. *Rhapontic Rhubarb.*

In the French works on pharmacy, two kinds of rhubarb are described under the name of Rhapontic, both derived from the *R. Rhaponticum*, but one the growth of France, the other of the native country of this species of Rheum. The former is in pieces of the size of the fist, ligneous in their appearance, of a reddish-gray colour on the outside, internally marbled with red and white arranged in the form of rays proceeding from the centre to the circumference, of a disagreeable odour, a mucilaginous and very astringent taste, not crackling under the teeth, but tinging the saliva yellow, and affording a reddish powder. The pieces of the latter are three or four inches long by two or three in thickness, and present characters very similar to those of the French, though less ligneous in their texture, and externally of a pale or brownish-yellow colour less inclining to redness. The Rhapontic rhubarb, though formerly in great repute, is little used at present, and seldom brought to this country; but as it is said to be sometimes employed in Europe to adulterate the better kinds, it may possibly be applied to the same purposes here; and our apothecaries should be able to distinguish it.

Choice of Rhubarb. In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a lively yellowish colour, brittle, presenting when broken a fresh appearance, with reddish and yellow veins intermingled with white, of an odour decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow mingled with orange. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation.

Chemical Properties. Rhubarb yields all its active properties to water and alcohol. The infusion is of a dark reddish-yellow colour, with the taste and odour of rhubarb; and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By boiling, the virtues of the medicine are diminished, in consequence probably of the evaporation of a volatile ingredient in which they partly reside. Many attempts have been made to analyze this important root, with various results. Among the most recen are those of the elder Henry and Caventou of Paris, Brande of London, and Peretti of Rome. From the analysis of M. Henry, it appears that rhubarb contains, 1. a peculiar yellow colouring matter; 2. a fixed oil which become rancid by heat, and is soluble in alcohol and ether; 3. starch; 4. gum; 5. tan nin; 6. lignin; 7. oxalate of lime; 8. supermalate of lime, sulphate of lime, salt of potassa, and oxide of iron, all in minute proportion. To these Pe retti adds sugar, a volatile oil, and gallic acid. Brande found gum, resin extractive, tannin, gallic acid, phosphate and malate of lime, lignin, an water. The extractive of Brande is probably a mixture of other principles among which is the yellow colouring matter of Henry. This last appear to be the most interesting ingredient. It is yellow, of the odour of rhubarb, of a bitter harsh taste, but slightly soluble in cold water, volatilizable by heat in yellow odorous vapours, dissolved and reddened by solutions of potassa and ammonia, precipitated yellow by acids and metallic salts generally, but green by the sulphate of iron, and converted by the action of nitric acid into artificial tannin. The name of *caphopicrite* has been proposed for it. It undoubtedly either contains, or is identical with the yellow matter obtained by Caventou, to which he has given the appropriate name of *rhabarbarin*, and which may be considered the distinctive principle of rhubarb in a pure state. *Rhabarbarin*, as procured by this chemist, is crystallizable; of a yellow colour, harsh bitter taste, and the odour of rhubarb; insoluble in cold water; soluble in hot water, alcohol and ether; and capable of forming insoluble compounds with all the acids. It does not, however, possess alkaline properties. It is probably the purgative principle of rhubarb. The oxalate of lime is another interesting ingredient, though possessed of no medicinal power. It is the substance which imparts the gritty feel to the Russian and Chinese rhubarb, of which, according to Scheele and Henry, it constitutes nearly one-third. The proportion, however, appears to be very variable, as Schrader found only 4.5 per cent. in Russian rhubarb; and Brande discovered none in the specimens which he examined. The European rhubarb contains but a small proportion of the oxalate, and has therefore little of the gritty feel when chewed. It contains, however, much more tannin and fecula than the Asiatic varieties. The existence of volatile oil in rhubarb, though highly probable, has not been satisfactorily demonstrated; at least it has not been obtained separate in a state of purity. The *rheumic* acid has proved to be the oxalic; and the sulphate of rhabarbarin of M. Nani, to be sulphate of lime coloured with extractive matter.

As all the active principles of rhubarb are extracted by alcohol and water, it is desirable to know the proportion of soluble matter in the different varieties. Chinese rhubarb is said to yield 70 parts out of 100 to these fluids; the European, from the *R. palmatum* 64 parts, from the *R. compactum* 50 parts, from the *R. undulatum* 32 parts, and from the *R. rhaponticum* 30 parts. (*Dict. des Drogues.*) Water at 212° takes up 40 per cent, of the Russian, and one-half of the Chinese; alcohol extracts 27 per cent. of the former, and 40 of the latter. (*London Dispensatory.*)

Medical Properties and Uses. The medical properties of rhubarb are peculiar and valuable. Its most remarkable singularity is the union of a cathartic with an astringent power; the latter of which, however, does not interfere with the former, as the purgative effect precedes the astringent. It is also tonic and stomachic; invigorating in small doses, the powers of digestion. It is not probable that these properties reside in a single proximate principle; and, as rhubarb owes its chief value to their combination, it is not to be expected that chemical analysis will be productive of the same practical advantages in this, as in some other medicines, the virtues of which are concentrated in one ingredient. In its purgative operation rhubarb is moderate, producing fecal rather than watery discharges, and appearing to affect the muscular fibre more than the secretory vessels. It sometimes occasions griping pain in the bowels. Its colouring principle is absorbed, and may be detected in the urine.

The circumstances of disease to which it is applicable may be inferred from its peculiar properties. When the stomach is enfeebled and the bowels relaxed, at the same time that a gentle cathartic is required, rhubarb, as a general rule, is preferable to all others. Hence its use in dyspepsia attended with constipation, in diarrhœa when purging is indicated, in the secondary stages of cholera infantum, in chronic dysentery, and in almost all typhoid diseases when fecal matter has accumulated in the intestines, or the use of cathartic medicine is necessary to prevent such accumulation. When employed in cases of habitual constipation, its astringent tendency should be counteracted by combining it with soap. Magnesia is also an excellent associate in disorders of the stomach and bowels. By combination with other cathartics, rhubarb frequently acquires additional activity, while it gives increased efficiency to the substance with which it is associated. A mixture of calomel and rhubarb is a brisk and powerful cathartic, much used in the commencement of our bilious fevers. As a general rule, rhubarb is not applicable to cases attended with much inflammatory action. Its griping effect may be counteracted by combining it with aromatics.

The dose of rhubarb as a purgative is from twenty to thirty grains, as a laxative and stomachic from five to ten grains. European rhubarb must be given in double or treble the dose to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal proportion of soap, when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup and tincture are also highly useful preparations. They are all officinal.

By the roasting of rhubarb its purgative property is diminished, while its astringency remains unaffected. This mode of treatment has, therefore, been sometimes resorted to in cases of diarrhœa. By long boiling the same effect is produced.

RHODODENDRI CHRYSANTHI FOLIA. *Ed.*

Leaves of the Yellow-flowered Rhododendron.

Rosage, *Fr.;* Gelbblühender Alpenbalsam, *Germ.;* Rhododendro aureo, *Ital.;* Sabina *Russian.*

Rhododendrum. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Ericeæ

Gen. Ch. Calyx five parted. *Corolla* nearly funnel-shaped. *Stamens* declined. *Capsule* five-celled. *Willd.*

Rhododendrum chrysanthum. Willd. *Sp. Plant.* ii. 605; Woodv. *Med Bot.* p. 299. t. 103. This is a beautiful evergreen shrub, about a foot high with spreading branches, and oblong, obtuse, thick leaves, narrowed toward their footstalks, reflexed at the margin, much veined, rugged and deep gree upon their upper surface, ferruginous or glaucous beneath, and surrounding th branches upon strong petioles. The flowers are large, yellow, on long peduncles, and arranged in terminal umbels. The corolla is wheel-shaped, wit its border divided into five roundish, spreading segments. The plant is a native of Siberia, delighting in mountainous situations, and flowering in Jun and July. The leaves are the part used in medicine.

When fresh they have a feeble odour, said to resemble that of rhubarb.

the dried state they are inodorous, but have an austere, astringent, bitterish aste. They yield their virtues to water and alcohol.

Medical Properties and Uses. The leaves of this species of Rhododendron are stimulant, narcotic, and diaphoretic, producing, when first taken, increase of heat and arterial action, subsequently a diminished frequency of he pulse, and in large doses, vomiting, purging, and delirium. They have een long employed by the natives of Siberia as a remedy in rheumatism, nd their use has extended to various parts of Europe. Their action is said o be accompanied with a sensation of creeping or pricking in the affected art, which subsides in a few hours, leaving the part free from pain. They ave been recommended also in gout, lues venerea, and palsy. In Siberia hey are prepared by infusing two drachms of the dried leaves in about ten unces of water, in a close earthen vessel, and keeping the liquid near the oiling heat during the night. The strained liquor is taken in the morning; nd a repetition of the dose three or four days successively generally effects cure. The remedy is not used in this country. W.

Off. Syn. PAPAVER RHŒAS. Petala. *Dub.*

Coquelicot, *Fr.;* Wilder Mohn, Klapperrose, *Germ.;* Rosolaccio, *Ital.;* Amapola, *Span.*

Papaver. See OPIUM.

Papaver Rhœas. Willd. *Sp. Plant.* ii. 1146; Woodv. *Med. Bot.* p. 387. . 139. The *red* or *corn poppy* is distinguished by its hairy stem, which s branched and rises about a foot in height, by its incised pinnatifid leaves, y its urn-shaped capsule, and by the full, bright, scarlet colour of its petals. t is a native of Europe, where it grows wild in great abundance, adorning specially the fields of grain with its brilliant flower. It has been introduced and naturalized in this country.

Its capsules contain the same kind of milky juice as that found in the . *somniferum*, and an extract has been prepared from them having the roperties of opium; but the quantity is too small to repay the trouble of s preparation. The petals are the officinal portion. They have a narcotic mell, and a mucilaginous slightly bitter taste. Chevallier has detected a ery minute proportion of morphia in an extract obtained from them (*Dict. es Drogues*); but their operation on the system is exceedingly feeble, and ey are valued more for their beautiful scarlet colour which they communicate to water, than for their medical virtues. They are rejected by the harmacopœias of the United States and of Edinburgh, but are recognised s officinal by those of London and Dublin, and by the French Codex. A yrup is prepared from them, which was formerly prescribed as an anodyne catarrhal affections; but is now little esteemed, except for the beauty of its olour.

RHUS GLABRUM. *U.S. Secondary.*

Sumach.

"Rhus glabrum. Baccæ. *The berries.*" *U.S.*

Rhus. *Sex. Syst.* Pentandria Trigynia.—*Nat. Ord.* Terebintaceæ, *Juss.*; Anacardiaceæ, *Lindley.*

Gen. Ch. *Calyx* five-parted. *Petals* five. *Berry* small, with one nuciform seed. *Nuttall.*

Of this genus there are several species which possess poisonous properties, and should be carefully distinguished from that here described. For an account of them the reader is referred to the article *Toxicodendron.*

Rhus glabrum. Willd. *Sp. Plant.* i. 1478. This species of Rhus, called variously *smooth sumach*, *Pennsylvania sumach*, and *upland sumach*, is an indigenous shrub from four to twelve feet high, with a stem usually more or less bent, and divided into straggling branches, covered with a smooth light gray or somewhat reddish bark. The leaves are upon smooth petioles, and consist of many pairs of opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their colour changes to a beautiful red. The flowers are greenish-red, and disposed in large, erect, terminal, compound thyrses, which are succeeded by clusters of small crimson berries covered with a silky down.

The shrub is found in almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and said to be used in tanning leather and in dyeing. Excrescencies are produced under the leaves resembling galls in character, and containing large quantities of tannin and gallic acid. These have been used as a substitute for the imported galls by Dr. Walters of New York, who thinks them, in every respect, preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States. (*A. W. Ives' edition of Paris's Pharmacologia.*) But the only officinal part of the plant is the berries.

These have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. According to Mr. Cozzens of New York, the acid to which they owe their sourness is the malic and is contained in the pubescence which covers their surface; as, when it is washed away by warm water, the berries are wholly free from acidity. Professor W. B. Rogers of Virginia found the acid combined with lime, in the state of bimalate.

Medical Properties and Uses. Sumach berries are astringent and refrigerant; and their infusion has been recommended as a cooling drink in febrile complaints, and a pleasant gargle in inflammation and ulceration of the throat. By Dr. Fahnestock an infusion of the inner bark of the root, employed as a gargle, is considered almost as a specific in the sore mouth attending inordinate mercurial salivation. (*Am. Journ. of Med. Sciences*, v. 61.) W.

ROSA CENTIFOLIA. *U. S.*

Hundred-leaved Roses.

"Rosa centifolia. Petala. *The petals.*" *U.S.*

Off. Syn. ROSÆ CENTIFOLIÆ PETALA. *Lond.*, *Ed,;* ROSA CENTIFOLIA. Petala. *Dub.*

Roses à cent feuilles, *Fr.;* Hunderblätteridge Rose, *Germ.;* Rosa pallida, *Ital.;* Rosa de Alexandria, *Span.*

Rosa. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. *Petals* five. *Calyx* urceolate, five-cleft, fleshy, contracted at the neck. *Seeds* numerous, hispid, attached to the inner side of the calyx. *Willd.*

Rosa centifolia. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 495. t. 178. This species of rose has prickly stems, which usually rise from three to six feet in height. The leaves consist of two or three pairs of leaflets, with an odd one at the end, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, usually of a pale red colour, and supported upon peduncles beset with short bristly hairs. The germ is ovate, and the segments of the calyx semi-pinnate. The varieties of the *R. centifolia* are very numerous, but may be indiscriminately employed. The plant is now cultivated in gardens all over the world; but its original country is not certainly known. It has sometimes been mistaken for the damask rose, which is a distinct species.

The petals are the officinal portion. They are extremely fragrant, and have a sweetish, slightly acidulous, somewhat bitterish taste. Their odour depends on a volatile oil, which may be separated by distillation with water, and is sold at a very high price, under the title of *essence* or *attar of roses.* It is furnished in very minute proportion, not more than three drachms having been obtained by Colonel Polier, in Hindostan, from one hundred pounds of the petals without the calyxes. It is prepared on a large scale in Egypt, Persia, Cashmire, India, and other countries of the East. In cool weather it is concrete; and adulterations with other volatile oils, which are very common, may thus be detected. The water which is distilled with the oil, has in a high degree the fragrance of the flower.

The petals are slightly laxative, and are sometimes administered in the form of syrup combined with cathartic medicines; but their chief use is in the preparation of rose-water.

Roses rouges, *Fr.;* Französische Rose, Essig-rosen, *Germ.;* Rosa domestica, *Ital.;* Rosa rubra o Castillara, *Span.*

Rosa. See ROSA CENTIFOLIA.

Rosa Gallica. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 498. t. 179. This species is smaller than the *R. centifolia*, but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson colour, and less numerous than in the preceding species. In the centre is a crowd of yellow anthers on thread-like filaments, and as many villose styles bearing papillary stigmas. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the South of Europe, and is cultivated in gardens throughout the United States.

The petals, which are the part employed, should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odour, which is less fragrant than that of the *R. centifolia*, is improved by drying. They have a pleasantly astringent and bitterish taste; and contain, according to M. Cartier, tannin, gallic acid, colouring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassa, insoluble salts of lime, silica, and oxide of iron. (*Journ. de Pharm.* vii. 531.) Their sensible properties and medical virtues are extracted by boiling water.

Medical Properties and Uses. Red roses are slightly astringent and tonic, and were formerly thought to possess peculiar virtues. They are at present chiefly employed in infusion, as an elegant vehicle for tonic and astringent medicines.

Rose sauvage, *Fr.;* Hundsrose, *Germ.*

Rosa. See ROSA CENTIFOLIA.

Rosa canina. Willd. *Sp. Plant.* ii. 1077; Woodv. *Med. Bot.* p. 493. t. 177. The *dog rose*, *wild briar*, or *heptree*, is a native of Europe, distinguished as a species by its glabrous ovate germs, its smooth peduncles, its prickly stem and petioles, and its ovate, smooth, rigid leaves. It rises eight or ten feet in height, and bears white or pale red flowers, having usually five obcordate fragrant petals. The plant has been introduced into this country, but is not much cultivated.

The fruit is a fleshy, smooth, oval, red berry, of a pleasant, sweet, acidulous taste, and contains sugar and uncombined citric acid.

The pulp, separated from the seeds and the silky bristles in which they are embedded, is employed in Europe for the preparation of a confection, intended chiefly as a pleasant vehicle for other medicines.

ROSMARINUS. *U.S.*

Rosemary.

"Rosmarinus officinalis. Cacumina. *The tops.*" *U.S.*

Off. Syn. ROSMARINI CACUMINA. *Lond.*; RORISMARINI OFFICINALIS CACUMINA. *Ed.;* ROSMARINUS OFFICINALIS. Cacumina. *Dub.*

Romarin, *Fr.;* Rosmarin, *Germ.;* Rosmarino, *Ital.;* Romero, *Span.*

Rosmarinus *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Labiatæ.

Gen. Ch. *Corolla* unequal, with the upper lip two-parted. *Filaments* long, curved, simple, with a tooth. *Willd.*

Rosmarinus officinalis. Willd. *Sp. Plant.* i. 126; Woodv. *Med. Bot.* p. 329. t. 117. Rosemary is an evergreen shrub, three or four feet high, with an erect stem, divided into many long, slender, ash-coloured branches. The leaves are numerous, sessile, opposite, more than an inch long, about one-sixth of an inch broad, linear, entire, obtuse at the summit, turned backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish and somewhat downy beneath. The flowers are pale blue or white, of considerable size, and placed in opposite groups at the axils of the leaves, towards the ends of the branches. The seeds are four in number, of an oblong shape, and naked in the bottom of the calyx.

The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The flowering summits are the officinal portion.

These have a strong balsamic odour, which is possessed, though in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on a volatile oil which may be obtained by distillation. (See *Oleum Rosmarini.*) The tops lose a portion of their sensible properties by drying, and become inodorous by age.

Medical Properties and Uses. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, &c., to which it imparts its agreeable odour and excitant property. It is sometimes added to sternutatory powders, and is used externally in connexion with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavour to the honey of the districts in which the plant abounds.

Garance, *Fr.;* Krappwurzel, *Germ.;* Robbia, *Ital.;* Rubia de tintoreros, Granza, *Span.*

Rubia. *Sex. Syst.* Tetrandria Monogynia.—*Nat. Ord.* Rubiaceæ.

Gen. Ch. *Corolla* one-petaled, bell-shaped. *Berries* two, one-seeded. *Willd.*

Rubia tinctorum. Willd. *Sp. Plant.* i. 603; Woodv. *Med. Bot.* p. 173. t. 67. The root of the *dyers' madder* is perennial, and consists of numerous long, succulent fibres, varying in thickness from the size of a quill to that of the little finger, and uniting at top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. These are slender, quadrangular, jointed, procumbent, and furnished with short prickles by which they adhere to the neighbouring plants upon which they climb. The leaves are elliptical, pointed, rough, firm, about three inches long and nearly one inch broad, having rough points on their edges and midrib, and standing at the joints of the stem in whorls of four, five, or six together. The branches rise in pairs from the same joints, and bear small yellow flowers at the summit of each of their subdivisions. The fruit is a round, shining, black berry.

The plant is a native of the South of Europe, and is cultivated in France and Holland. It is from the latter country that commerce derives its chief supply. The root, which is the part used, is dug up in the third summer, and having been deprived of its cuticle, is dried by artificial heat, and then reduced to a coarse powder. In this state it is packed in barrels, and sent into the market.

The root is invested with a brown epidermis, but is internally throughout its whole substance of a deep-red colour. The powder, as kept in the shops, is brownish-red.

Madder has a weak peculiar odour, and a bitterish astringent taste; and imparts these properties, as well as a red colour, to water and alcohol. Among its constituents are two colouring principles, one of which, named by Robiquet and Collin *alizarin*, is of an orange-red colour, inodorous, insipid, crystallizable, capable of being sublimed without change, scarcely soluble in cold water, soluble in boiling water, and very readily so in alcohol, ether, the fixed oils, and liquid alkalies. The alcoholic and watery solutions are rose-coloured; the ethereal, golden-yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-coloured lake is produced by precipitating a mixture of the solutions of alizarin and alum. The other colouring principle is yellow, and named *xanthin* by Kuhlmann. It is very soluble in water, soluble in alcohol, scarcely so in ether. Its solution is made orange-red by the action of the alkalies, and citron-yellow by that of the acids. It has a sweetish bitterish taste. Madder also contains sugar; and Döbereiner succeeded in obtaining alcohol from it by fermentation and distillation, without affecting its colouring properties. It is much used by the dyers.

Medical Properties and Uses. Madder was formerly thought to be emmenagogue and diuretic; and was used in amenorrhœa, dropsy, jaundice, and visceral obstructions. It is still occasionally prescribed in suppressed menstruation; but physicians generally have no confidence in its efficacy in this or any other complaint. When taken into the stomach it imparts a red colour to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in rachitis, but without any favourable result. The dose is about half a drachm, repeated three or four times a day. W.

RUBUS TRIVIALIS. *U.S. Secondary.*

Dewberry-root.

"Rubus trivialis. Radix. *The root.*" *U.S.*

Rubus. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. *Calyx* five-cleft. *Petals* five. *Berry* compound, with one-seeded acini. *Willd.*

Of this extensive genus not less than twenty species are indigenous in the United States, where they are called by the various names of *raspberry*, *blackberry*, *dewberry*, *cloudberry*, *&c.* Most of them are shrubby or suffruticose briers, with astringent roots and edible berries; some have annual stems without prickles. The only officinal species are the *R. trivialis* and *R. villosus*, which, so far as relates to their medical properties, are so closely alike, as not to require a separate description.

1. *Rubus trivialis.* Michaux, *Flor. Americ.* i. 296. The *dewberry*, sometimes also called *low-blackberry*, or *creeping blackberry*, has a slender, prickly stem, which runs along the ground, and occasionally puts forth roots. The leaves are petiolate, and composed of three or five leaflets, which are oblong oval, acute, unequally serrate, and somewhat pubescent The stipules are awl-shaped. The flowers are large, white, and nearly solitary, with elongated pedicels, and peduncles, which, like the leafstalks, are armed with recurved, hispid prickles. The petals are generally obovate, and three times longer than the calyx. In one variety they are orbicular. The plant grows abundantly in old fields and neglected grounds in all parts of the United States. Its fruit is large, black, of a very pleasant flavour, and ripens somewhat earlier than that of the *R. villosus*.

2. *R. villosus.* Willd. *Sp. Plant.* ii. 1085; Bigelow, *Am. Med. Bot.* ii. 160; Barton, *Med. Bot.* ii. 151. The stem of the blackberry is somewhat shrubby, from three to seven feet high, branching, more or less furrowed and angular, and armed with strong prickles. The smaller branches and young shoots are herbaceous. The leaves are ternate or quinate; the leaflets ovate, acuminate, unequally and sharply serrate, and pubescent on both sides; the footstalk and midrib usually armed with short recurved prickles. The flowers are large, white, and in erect racemes, with a hairy, prickly stalk. The calyx is short, with acuminate segments. The fruit is first green, then red, and when perfectly ripe, of a shining black colour, and very pleasant taste. It is a compound berry, consisting of numerous pulpy one-seeded globules or acini attached to the receptacle. This species of Rubus is, perhaps, the most abundant of those indigenous in the United States, growing in neglected fields, along fences, on the borders of woods, in forest glades, and wherever tillage or too much shade and moisture does not interfere with it. Its flowers appear from May to July, and its fruit is ripe in August.

The berries of both these species of Rubus are much used as food; and a jelly made from them is in great esteem as an article of diet, and even as a remedy in dysenteric affections. The roots only are officinal.

These are branching, cylindrical, of various dimensions, from nearly an inch in thickness down to the size of a straw, ligneous, and covered with a thin bark, which is externally of a light brownish or reddish-brown colour. The root is inodorous. The bark has a bitterish strongly astringent taste, the ligneous portion is nearly insipid, and comparatively inert. The smaller roots, therefore, should be selected for use; or if the thicker pieces are employed, the cortical part should be separated, and the wood rejected. The virtues of the root are extracted by boiling water, and by diluted alcohol. They depend chiefly, if not exclusively, upon tannin, which experiment has proved to be an abundant constituent.

Medical Properties and Uses. Dewberry and blackberry roots are tonic and strongly astringent. They have long been a favourite domestic remedy in bowel affections; and from popular favour have passed into regular medical use. Given in the form of decoction, they are usually acceptable to the stomach, without being offensive to the taste; and may be employed with great advantage in cases of diarrhœa from relaxation of the bowels, whether in children or adults. We can add our own decided testimony to that of others who have spoken favourably of their use in this complaint; and there is no doubt that they are applicable to all other cases in which the vegetable astringents are found serviceable. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint; of which from one to two fluidounces may be given to an adult three or four times, or more frequently during the twenty-four hours. The dose of the powdered root is twenty or thirty grains.

RUMEX AQUATICUS. Radix. *Dub.*

Water Dock Root.

RUMEX BRITANNICA. *U.S. Secondary.*

Water Dock.

"Rumex Britannica. Radix. *The root.*" *U.S.*

RUMEX OBTUSIFOLIUS. *U.S. Secondary.*

Blunt-leaved Dock.

"Rumex obtusifolius. Radix. *The root.*" *U.S.*

Rumex. *Sex. Syst.* Hexandria Trigynia.—*Nat. Ord.* Polygoneæ.

Gen. Ch. Calyx three-leaved. *Petals* three, converging. *Seed* one, three-sided. *Willd.*

Calyx six-parted, persistent, the three interior divisions petaloid, connivent. *Seed* one, three-sided, superior, naked. *Stigmata* multifid. *Nuttall.*

We have placed together the three officinal species of dock, because their virtues are so nearly alike that a separate consideration would lead to unnecessary repetition. The roots of several other species have been medicinally employed. Those of the *R. Patientia*, and *R. alpinus*, European plants, and of the *R. crispus*, *R. acutus*, and *R. sanguineus*, which belong both to Europe and the United States, are recognised by the French

Codex, and may be used indiscriminately with those which are considered officinal with us. Several species of Rumex have acid leaves, which are sometimes used in medicine. Such are the *R. Acetosa*, *R. Acetosella*, and *R. scutatus*. These are more particularly noticed in another place. (See *Acetosæ Folia.*)

The docks are herbaceous plants with perennial roots. Their flowers are in terminal or axillary panicles. Some of the species are diœcious; but all those here described have perfect flowers.

1. *Rumex aquaticus*. Willd. *Sp. Plant.* ii. 255; Woodv. *Med. Bot.* p. 658. t. 229. The *water dock* has a large thick root, externally black, internally whitish, with an erect stem from three to five feet high, furnished with smooth, lanceolate, pointed leaves, of which the lower are cordate at their base. The three petals, or, as some botanists consider them, the three interior divisions of the calyx, approach each other so as to assume a triangular shape, and in this state are called *valves*. These are large, ovate, entire, and are each furnished with a small, linear, often obscure grain, extending down the middle. The plant is a native of Europe, but naturalized in America. It grows in this country in small ponds and ditches, and flowers in July and August. It is thought to be the *Herba Britannica* of the ancients, celebrated for the cure of scurvy and diseases of the skin.

2. *R. Britannica*. Willd. *Sp. Plant.* ii. 250. This species is distinguished in the vernacular language by the name of *yellow-rooted water dock*. The root is large, dark on the outside, and yellow within. The stem is two or three feet high, and bears broad lanceolate, smooth, flat leaves, with the sheathing stipules slightly torn. The spikes of the panicle are leafless; the valves entire and all graniferous. The plant is indigenous, inhabiting low, wet places, and flowering in June and July.

3. *R. obtusifolius*. Willd. *Sp. Plant.* ii. 254; Loudon's *Encyc. of Plants*, p. 293. The root of the *blunt-leaved dock* is externally brown, internally yellow; the stem two or three feet high and somewhat rough; the radical leaves ovate cordate, obtuse, and very large; the valves dentate and one of them conspicuously graniferous. It is a common weed in our rich grounds and pastures, but is supposed to have been introduced from Europe. Its flowers appear in June and July.

4. *R. crispus*. Willd. *Sp. Plant.* ii. 251. This common species, though not officinal, is perhaps equally entitled to notice with those which are so. It has a yellow, spindle-shaped root, with a smooth furrowed stem two or three feet high, and lanceolate, waved, pointed leaves. The valves are ovate, entire, and all graniferous. It is a native of Europe, and grows wild in this country. It is common in our dry fields and pastures, and about barn yards, and flowers in June and July.

Dock-root, from whatever species derived, has an astringent bitter taste, with little or no smell. It readily yields its virtues to water by decoction. It has not been accurately analyzed; but, according to M. Deyeux, the root of the common European dock (*R. Patientia*) contains, among other ingredients, sulphur, starch, and acetate of lime. The leaves of most of the species are edible, and are occasionally used as spinage. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow colour.

Medical Properties and Uses. The medical properties of dock-root are those of an astringent and mild tonic. It is also supposed to possess an alterative property, which renders it useful in scorbutic disorders, and cutaneous eruptions, particularly the itch, in the cure of which it enjoyed at one time considerable reputation. It is said to have proved useful also in syphilis.

Dr. Thomson found a decoction of the root of the *R. Patientia* very efficacious in obstinate ichthyosis. (*London Dispensatory.*) The *R. aquaticus*, and *R. Britannica*, are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of the *R. crispus* and *R. obtusifolius*; and the *R. alpinus* has in some parts of Europe the common name of *mountain rhubarb*. (*Paris Codex.*) This resemblance of properties is not singular, as the two genera belong to the same natural family. Dock-root is given in powder or decoction. Two ounces of the fresh root bruised, or one ounce of the dried, may be boiled in a pint of water, of which two fluidounces may be given at a dose, and repeated as the stomach will bear it. The root has often been applied externally in the shape of ointment, cataplasm, and decoction, to the various cutaneous eruptions and ulcerations for which its internal use is recommended. The powdered root is recommended as a dentifrice, especially when the gums are spongy. W.

RUTÆ FOLIA. *Lond.*

Rue Leaves.

"Ruta graveolens. *Folia.*" *Lond.*

Off. Syn. RUTÆ GRAVEOLENTIS HERBA. *Ed.;* RUTA GRAVEOLENS. Folia. *Dub.*

Rue odorante, *Fr.;* Garten-Raute, *Germ.;* Ruta, *Ital.;* Ruda, *Span.*

Ruta. *Sex. Syst.* Decandria Monogynia.—*Nat. Ord.* Rutaceæ.

Gen. Ch. *Calyx* five-parted. *Petals* concave. *Receptacle* surrounded by ten melliferous points. *Capsule* lobed. *Willd.*

Ruta graveolens. Willd. *Sp. Plant.* ii. 542; Woodv. *Med. Bot.* p. 487. t. 174. Common rue is a perennial plant, usually two or three feet high, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are doubly pinnate, glaucous, with obovate, sessile, obscurely crenate, somewhat thick and fleshy leaflets. The flowers are yellow, and disposed in a terminal branched corymb upon subdividing peduncles. The calyx is persistent, with four or five acute segments; the corolla consists of four or five concave petals somewhat sinuate at the margin. The stamens are usually ten, but sometimes only eight in number. The plant is a native of the South of Europe, but cultivated in our gardens. It flowers from June to September. The whole herbaceous part is active; but the leaves are usually employed.

These have a strong disagreeable odour, especially when rubbed. Their taste is bitter, hot, and acrid. In the recent state, and in full vigour, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminishsd by drying. Their virtues depend chiefly on a volatile oil which is very abundant, and is contained in glandular vesicles, apparent over the whole surface of the plant. Besides volatile oil, they contain, according to Mähl, chlorophylle, albumen, an azotized substance, extractive, gum, starch or inulin, malic acid, and lignin. Both alcohol and water extract their active properties.

Medical Properties and Uses. Rue is stimulant and antispasmodic, and like most other substances which excite the circulation, occasionally increases the secretions, especially when they are deficient from debility. It is sometimes used in hysterical affections, flatulent colic, and amenorrhœa, particularly in the last complaint. It has also been given in worms. The ancients employed it as a condiment, and believed it to possess, besides other valuable properties, that of resisting the action of poisons. Its excitant and irritating properties require that it should be used with caution. The dose of the powder is from fifteen to thirty grains two or three times a day. The medicine is also given in infusion and extract.

SABBATIA. *U. S.*

American Centaury.

"Sabbatia angularis. Herba. *The herb.*" *U. S.*

This is the *Chironia angularis* of Linnæus, but as it wants some of the essential characters of the genus Chironia, it has been separated from it by subsequent botanists, and now ranks in the genus *Sabbatia* of Adanson.

Sabbatia. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianeæ.

Gen.Ch. *Calyx* five to twelve-parted. *Corolla* rotate, five to twelve-parted. *Stigmas* two, spiral. *Anthers* at length revolute. *Capsule* one-celled, two-valved, many-seeded. *Nuttall.*

Sabbatia angularis. Pursh, *Flor. Am. Sept.* 137; Bigelow, *Am. Med. Bot.* iii. 147; Barton, *Med. Bot.* i. 255. The American centaury is an annual or biennial herbaceous plant, with a fibrous root, and an erect, smooth, four-sided stem, winged at the angles, simple below, sending off opposite axillary branches above, and rising one or two feet in height. The leaves, which vary considerably in length and width, are ovate, entire, acute, nerved, smooth, opposite, and sessile, embracing half the circumference of the stem at their base. The flowers are numerous, growing on the ends of the branches, and forming altogether a large terminal corymb. The calyx is divided into five lanceolate segments, considerably shorter than the corolla. This is deeply five parted, with obovate segments of a beautiful delicate rose-colour, which is paler and almost white in the middle of their under surface. The anthers are yellow, and after shedding their pollen become revolute. The style, which is bent downward and longer than the stamens, terminates in two linear stigmas, which become spirally twisted together.

The plant is widely diffused through the Middle and Southern States, growing in low meadow grounds, and in wet seasons upon uplands, in woods and neglected fields. It flowers in July and August. In its general aspect as well as medical properties, it bears a close resemblance to the *Erythræa*, formerly *Chironia Centaurium*, or European centaury, for which it was mistaken by the earlier settlers. The whole herb is employed, and should be collected when in flower.

All parts of it have a strongly bitter taste, without any admixture of astringency or other peculiar flavour. Both alcohol and water extract its bitterness, together with its medical virtues.

Medical Properties and Uses. American centaury has the tonic properties of the simple bitters, and is very analogous in its action to the other plants belonging to the same natural family. It has long been popularly employed as a prophylactic and remedy in our autumnal intermittent and remittent fevers; and has found much favour with the medical profession in the latter of these complaints. The state of the fever to which it is particularly applicable, is that which exists in the intervals between the paroxysms, when the remission is such as to call for the use of tonics, but is not sufficiently decided to justify a resort to the preparations of Peruvian bark. It is also occasionally useful during the progress of a slow convalescence, by promoting appetite and invigorating the digestive function; and may be employed for the same purpose in dyspepsia and diseases of debility.

The most convenient form of administration is that of infusion. A pint of boiling water poured on an ounce of the herb and allowed to cool, may be given in the dose of two fluidounces, repeated every hour or two during the remission of fevers, and less frequently in chronic affections. The dose of the powder is from thirty grains to a drachm. The decoction, extract, and tincture are also efficient preparations. W.

SABINA. *U.S.*

Savine.

"Juniperus sabina. Folia. *The leaves.*" *U.S.*

Off. Syn. SABINÆ FOLIA. *Lond.;* JUNIPERI SABINÆ FOLIA. *Ed.;* JUNIPERUS SABINA. Folia. *Dub.*

Sabine, *Fr.;* Sevenbaum, *Germ.;* Sabina, *Ital., Span.*

JUNIPERUS. See JUNIPERUS.

Juniperus Sabina. Willd. *Sp. Plant.* iv. 852; Woodv. *Med. Bot.* p. 10. t. 5. This is an evergreen shrub, rising from three or four feet to fifteen feet in height, with numerous erect, pliant branches, very much subdivided. The bark of the young branches is light green, that of the trunk, rough and reddish-brown. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, of a dark green colour, glandular in the middle, opposite, and imbricated in four rows, The flowers are male and female on different trees. The fruit is a blackish-purple berry, of an ovoid shape, marked with tubercles, the remains of the calyx and petals, and containing three seeds.

The savine is a native of the South of Europe and the Levant. It is said also to grow wild in the neighbourhood of our Northwestern lakes. The ends of the branches, and the leaves by which they are invested, are collected for medical use in the spring. When dried they fade very much in colour.

There is reason to believe that the *Juniperus Virginiana*, or common red cedar, is sometimes substituted in the shops for the savine, to which it bears so close a resemblance as to be with difficulty distinguished. The two species, however, differ in their taste and smell. In the *J. Virginiana*, moreover, the leaves are sometimes ternate.

The tops and leaves of savine have a strong, heavy, disagreeable odour, and a bitter, acrid taste. These properties are owing to a volatile oil which is obtained by distillation with water. (See *Oleum Sabinæ.*) They impart their virtues to alcohol and water.

Medical Properties and Uses. Savine is highly stimulant, increasing most of the secretions, especially those of the skin and uterus, to the latter of which organs it is supposed to have a peculiar direction. It has been much used in amenorrhœa, and occasionally as a remedy for worms. Dr. Chapman strongly recommends it in chronic rheumatism. At present, however, it is not generally employed; and in no case should it be given when much general or local excitement exists. In pregnancy it should always be avoided. It is most conveniently administered in the form of powder, of which the dose is from five to fifteen grains, repeated three or four times a day.

As an external irritant it is very useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as the preparation sold in this country under the name of savine ointment, is often deficient in power, either from the age of the drug or the substitution of red cedar, it has in some measure fallen into disrepute. (See *Ceratum Sabinæ.*) In the state of powder or infusion, savine is used in Europe as an application to warts, indolent, carious, and gangrenous ulcers, psora, and tinea capitis; and the expressed juice of the fresh leaves, diluted with water, is sometimes applied to similar purposes.

Sugar is a peculiar organic principle, neither acid nor alkaline, which is derived principally from vegetables, though occasionally from animal matter. As obtained from different sources, it presents shades of difference in its properties; and this circumstance has given rise to a number of varieties of this organic principle, distinguished by names derived from their source or mode of preparation. According to strict definition, no substance is considered a sugar, unless it be susceptible of the vinous fermentation; but we shall not use the term in this restricted sense; but call every substance a species of sugar which has more or less of the saccharine taste.

Sugar is found in the fruit, roots, and sap of many vegetables. All the sweet fruits contain it, especially the grape, which furnishes a distinct variety of sugar; and it is present, in larger or smaller amount, in the turnip, the onion, and the beet. This latter root is cultivated extensively in France for the purpose of yielding sugar; and it was supposed in 1830 that one-twentieth of the immense consumption of that country was furnished from this source alone, and the proportion of the domestic supply to the foreign is annually increasing. In the north-western parts of the United States, as well as in Canada, considerable quantities of sugar are manufactured from the sap of the sugar maple (*Acer saccharinum*). The process pursued is described by Dr. Rush in a paper published in the third volume of the American Philosophical Transactions. But the supply of sugar from the above sources is insignificant compared with that obtained from the sugar cane, which is extensively cultivated in the East and West Indies, Brazil, and some of our Southern States, particularly Louisiana, for the purpose of being manufactured into sugar. This plant is the *Saccharum officinarum* of botanists, and is the source of the officinal sugars of the Pharmacopœias.

Saccharum. *Sex. Syst.* Triandria Digynia.—*Nat. Ord.* Gramineæ.

Gen. Ch. *Calyx* two-valved, involucred, with long down. *Corolla* two-valved. *Willd.*

Saccharum officinarum. Willd. *Sp. Plant.* i. 321; *Phil. Trans.* lxix. 207. The sugar cane is an herbaceous plant, possessing a jointed, succulent root, from which arise several shining, jointed stems, from an inch to an inch and a half in diameter and eight or ten feet high, and containing a white and juicy pith. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long, and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green colour inclining to yellow. The flowers are whitish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant may be said to have a general resemblance to the Indian corn. There are two varieties, the common and the Otaheitan, the latter of which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh. It is distinguished by its greater height, the longer intervals between its joints, and by the greater length of the hairs which surround the flowers.

The sugar cane is a native of the tropical regions of both the old and new continents. It is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be renewed. At the end of a year the plant generally flowers, and in four or five months afterwards, the canes are completely ripe, at which time they have a yellowish colour, and contain a sweetish viscid juice. The quantity of sugar which they yield is very variable, ranging from six to fifteen per cent. Its separation is founded upon its property of crystallization, which is possessed by the sugar alone of all the substances present in the juice.

Preparation and Purification. The canes being ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between iron rollers in a kind of mill. The juice, as it runs out, is received in suitable vessels, and being quickly removed, is immediately mixed with lime in the proportion of one part to eight hundred of the juice, and heated in a boiler to 140°. The gluten and albumen combine with the lime, and form a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by ebullition, the froth being carefully skimmed off as it forms. When sufficiently concentrated, it is transferred to shallow vessels called coolers, from which, before it is cool, it is drawn off into wooden vessels, with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours, the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup allowed to drain off from the sugar, which in this state is granular, of a yellowish colour, and moist. It is next dried in the sun, and being introduced into hogsheads, forms the *brown sugar* of commerce. The syrup, by a new evaporation, furnishes an additional portion of sugar; and the portion which finally remains, incapable of yielding more sugar, is the liquid called *molasses*. Sometimes the brown sugar undergoes an additional preparation, consisting in boiling it with lime-water, and, after sufficient concentration, allowing the syrup to crystallize in large inverted conical vessels, pierced at the apex and plugged. The surface of the crystalline mass being covered with a thin mixture of clay and water, the plug is removed, and the water from the clay penetrating the mass, removes the coloured syrup, which flows out at the hole. The sugar in this state approaches to the white state, and constitutes the clayed sugar of commerce, usually called in this country *Havana sugar*. It is still, however, far from being pure.

The purification of brown sugar constitutes a distinct branch of business, and the methods pnrsued have undergone many changes and improvements. By the original process, the sugar was boiled with lime-water, and clarified by means of bullocks' blood. These agents have the effect of combining with the impurities, which rise to the surface, and are removed. The clarified syrup is then strained through a woollen cloth, whereby it is rendered limpid. It is next transferred to a boiler, where it is subjected to ebullition, until it is brought to a proper concentration, when it is allowed to cool in conical moulds, and to drain for the separation of the molasses. This last boiling requires to be continued so long, that the action of the fire and air frequently decomposes the sugar to such an extent, as to cause a loss of twenty-five per cent. in molasses. This disadvantage has caused the process above described to be very generally abandoned since the year 1812; and now, for the most part, the sugar refiners boil the syrup in shallow boilers, which are suspended in such a way as to admit of their being emptied with the greatest quickness, without putting out the fire. By this arrangement, ten minutes are a sufficient time for boiling, and thus any considerable decomposition of the sugar is avoided.

The process of refining has been still further improved by Messrs. Philip Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity by means of steam, made to pass through a series of tubes traversing the boiler; and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction pump, set in motion by a steam engine, while it was heated by steam, circulating round the boiler. In this way, the syrup was made to boil at a low temperature, and without contact with the air, the two conditions most favourable to the formation of crystallizable sugar.

After the syrup is sufficiently boiled by any of these methods, it is transferred into a large vessel to cool, and afterwards poured into unglazed earthenware moulds of a conical shape, with a hole in the apex, which is stopped with a plug of linen. The moulds are placed, with the apex downwards, above stone-ware pots, intended to receive the uncrystallizable syrup. While the mass is cooling it is stirred, to cause the sugar to granulate, and when it has completely concreted, the moulds are unstopped, to allow the syrup to drain off. This syrup constitutes *sugar house molasses*. To remove the remains of the coloured syrup, the operation called *claying* is performed. This consists in removing from the base of the cones, a layer of the sugar, about an inch thick, and replacing it with pure sugar in powder, which is covered with a mixture of pipe clay and water, of about the consistence of cream. The water gradually leaves the clay, dissolves the pure sugar, and percolates the mass as a pure syrup, removing in its progress the coloured syrup. When this is all removed, the loaf is taken out of the mould and placed in stoves to dry. It now constitutes *white* or *purified sugar*.

Latterly bullocks' blood has gone very much out of use, and animal charcoal has been substituted, in the proportion of from four to fourteen per cent. of the weight of the sugar. The sugar purified in this way is perfectly white. Sometimes the boiling is performed by means of heated whale oil, contained in serpentine tubes, which traverse the syrup, and into which the oil is drawn by a suction pump. This plan, first put in practice by an English refiner of the name of Daniel Wilson, affords the means of heating the syrup rapidly without the risk of burning it, and of withdrawing the heat in an instant, by stopping the action of the pump.

Of the several forms of sugar above indicated, as resulting from the various steps for its preparation, three only, *white* and *brown sugar*, and *molasses*, are officinal in the British and United States Pharmacopœias; and these are designated by the scientific names placed at the head of this article. The United States Pharmacopœia recognises refined sugar only, which it names *Saccharum;* the uses of brown sugar and molasses being replaced by the employment of a prepared syrup of known strength. (See *Syrupus.*) The three British Colleges admit both purified and brown sugar, and the Edinburgh and Dublin Colleges, molasses, under the appropriate name of *Syrupus Empyreumaticus*; but unfortnnately the United States Pharmacopœia calls *purified* sugar *Saccharum*, being the same name employed by the London College to denote the *unpurified*.

Commercial History. Sugar has been known from the earliest ages, and was originally obtained from Asia. About the period of the Crusades, the Venetians brought it to Europe; but at that time it was so scarce as to be exclusively used as a medicine. Upon the discovery of the Cape of Good Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Subsequently the cultivation o the cane was extended to Arabia, Egypt, Sicily, Spain, and the Canaries and finally, upon the discovery of the new world, to America, where it was carried on with the greatest success, and continues to be so up to the presen day. After this time, sugar became comparatively so cheap and abundant that, from being viewed as a medicine and costly luxury, it came into almos universal use among civilized nations, as an article of food. In America i is produced most abundantly in the West Indies, which supply the greate part of the consumption of Europe, little comparatively being brought from the Brazils or the East Indies. The consumption of the United States which in the year 1829 was estimated at one hundred and fifty millions pounds, is more than half supplied by Louisiana and some of the neighbouring States, the remainder being received principally from the West Indies. It is not unlikely, that before many years shall have passed, all th sugar consumed in the United States will be furnished by the sugar-growin States. Within a few years, our planters have introduced into Louisian the variety of cane called the Otaheite or ribbon cane, which is hardier an more productive than the common cane, and better suited to the climate our Southern States.

Properties and Varieties. Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosporescent by friction, and of the sp. gr. 1.6. It dissolves readily in half its weight of cold water, and to almost an unlimited extent in boiling water. The solution, when thick and ropy, is called *syrup*, and forms, by spontaneous evaporation, white, semi-transparent crystals, having the shape of oblique four-sided prisms, and called *sugar-candy*. Sugar is nearly insoluble in absolute alcohol, but dissolves in four times its weight of boiling alcohol of the sp. gr. 0.83. Exposed to heat it swells, undergoes fusion, is decomposed, and exhales a peculiar odour, called *caromel.* Subjected to destructive distillation, it yields an acid water mixed with empyreumatic oil, and as gaseous products, a mixture of hydrogen, carburetted hydrogen, carbonic oxide, and carbonic acid; and there remains in the retort one-fourth of its weight of charcoal, which burns without residue. Dissolved in water and mixed with a ferment, it undergoes the vinous fermentation, and is converted into carbonic acid and alcohol. (See *Alcohol.*) By the action of strong sulphuric acid it is blackened and decomposed; and by a prolonged ebullition with the same acid in a dilute state, is converted into a sugar, identical with the sugar of grapes. Nitric acid converts it into oxalic acid. (See *Acidum Oxalicum.*) Sugar has the property of combining with some salifiable bases, as potassa, ammonia, lime, and protoxide of lead, and forming with them definite compounds called *saccharates*. It renders the fixed and volatile oils to a certain extent miscible with water, and forms with the latter a kind of combination, called in pharmacy *oleo-saccharum.* When in solution, it is not precipitated by subacetate of lead, a negative property by taking advantage of which it may be separated from most other organic principles.

Besides cane sugar, chemists distinguish four other kinds; namely, the sugars severally obtained from *grapes, manna, mushrooms*, and *liquorice.* (See *Manna* and *Glycyrrhiza.*) Maple and beet sugar are the same as that of the cane. The artificial sugars, obtained by the action of dilute sulphuric acid severally on starch and ligneous fibre, are identical with the sugar of grapes. Besides these varieties, there are several saccharine substances of animal origin, such as *honey, sugar of milk*, and *sugar of diabetes.* The three officinal forms of the saccharine principle, *white* and *brown sugar*, and *molasses*, are mere varieties of cane sugar, the two former in the crystalline, the latter in the uncrystallizable state.

Purified or *white sugar*, as obtained in the arts, is in concreted somewhat porous masses, consisting of an aggregate of small crystalline grains, and possessing the general properties of sugar, as already described. When pure it is brittle and pulverulent, perfectly white, inodorous, and possessed of the pure saccharine taste. It may be viewed as the type of the class of saccharine substances.
